**Raman effect in diatomic gases. II.** F. RASETTI. *Proc. Natl. Acad. Sci.* 15, 515-9 (1929); cf. C. A. 23, 2885.—The quantum-mech. explanation of the patterns of Raman lines due to rotational transitions in sym. mols. is given. As shown by Heisenberg and Hund the whole system of terms splits into 2 classes according to the property of the total eigenfunction of being sym. or antisym. in the coordinates of the nuclei. If the nuclei have no spin only 1 of the 2 classes exists. This occurs in  $He_2$  and  $O_2$ . In the presence of a nuclear spin both classes of terms exist but they are practically non-combining because of the extremely weak coupling between nuclear spins.  $N_2$  and  $H_2$  are of this class. The observed patterns are in accordance with the theory.  $O_2$  gives a pattern of 6 or 7 equally spaced lines of diminishing intensity on either side of the unmodified line.  $N_2$  shows a pattern of alternating intensities arising from the 2 types of terms. An important feature of the exptl. work is the use of the Hg line  $\lambda$  2536, which is in a region where the scattering is much stronger than in the visible spectrum and the dispersion great enough to permit the use of a quartz spectrograph.

C. J. HUMPHREYS

**Influence of temperature on the x-ray liquid haloes.** V. I. VAIDYANATHAN. *Indian J. Physics* 3, 391-8 (1929).—The thermal effect on the x-ray diffraction haloes of cam-

phene, mesitylene, AcOH, butyric acid and ethyl alc. was investigated with Cu K $\alpha$  radiation at 30° and 130° to 150°. Camphene has a single halo, whereas the others have two. As a consequence of the temp. rise there is (1) an increase in scattering at small angles, (2) an increase in the diffuseness of the halo, and (3) a contraction of the radius of the haloes as predicted by theory. In the case of AcOH, butyric acid and EtOH, which are associated at ordinary temps. and dissociated at higher temps., the sepn. between the inner and outer halo tends to be strikingly effaced with the temp. increase, the inner halo becoming diffuse more quickly than the outer one. The various phenomena are interpreted on the basis of the theory of Raman and Ramanathan.

H. W. WALKER

**Difference between the absorption and the Raman spectrum.** G. H. DIEKE *Nature* 123, 564(1929).—The fact that Raman lines are found which do not correspond with infra-red absorption frequencies is a proof rather than a contradiction of the validity of Kramer's theory of dispersion, which includes the theory of the Raman effect.

H. F. JOHNSTONE

**Raman effect and fluorescence.** PAUCHANON DAS. *Nature* 123, 607(1929).—Simple probability considerations reveal an interesting relation between fluorescence and the modified scattering of light.

H. F. JOHNSTONE

**The photochemical reaction between glucose and hydrogen peroxide in acid medium with tungstic acid sol as photocatalyst.** I. J. C. GHOSH AND JADULAL MUKHERJEE. *J. Indian Chem. Soc.* 6, 231-8(1929).—G. and M. have studied the photochem. reaction between H<sub>2</sub>O<sub>2</sub> and glucose in HCl solns. with Na<sub>2</sub>WO<sub>4</sub> present as a photocatalyst in the region 330-430 m $\mu$  (Corning filter G 586) from a quartz-Hg arc. There is a period of induction but the monomol. velocity const. with respect to H<sub>2</sub>O<sub>2</sub> after an interval of 1 hr. exposure agree well in themselves (av. 0.0041). The velocity const. is very roughly proportional to the square root of the concn. of the free HCl; the values of the const. pass through a max. as concn. of Na<sub>2</sub>WO<sub>4</sub> varies from 0.025 to 0.0036 M; variation of the glucose concn. is practically without effect. The temp. coeff. is 1.3 for 10°. A mechanism is derived on the basis of the adsorption on the surface of the particles of the WO<sub>3</sub> sol of H<sup>+</sup> and H<sub>2</sub>O<sub>2</sub> (the adsorption to form a peroxide complex is corroborated by other workers). Activation of the peroxide surface is assumed and

from a consideration of possible kinetics is obtained the equation  $dx/dt = k_1 \frac{CH_2O_2}{\sqrt{C_{H^+}}}$

WILLIAM E. VAUGHAN

**Influence of the variation of intensity on the velocity of the decomposition of ferric thiocyanate and the bleaching of neocyanin and some other photochemical reactions.** A. K. BHATTACHARYA AND N. R. DHAR. *J. Indian Chem. Soc.* 6, 197-205(1929).—B. and D. have investigated 7 reactions under the influence of the radiation from a 1000-w. gas-filled W-filament lamp with varying intensities as secured by change in the aperture of an iris diaphragm between the source and the reaction vessel. (a) Decompn. of ferric thiocyanate, (b) bleaching of neocyanin, (c) reaction between citric and chromic acids, and (d) reaction between tartaric and chromic acids all have velocities proportional to the square root of the incident intensity. The reactions of (e) Na lactate and I, (f) Na tartrate and I, and (g) lactic and chromic acids have velocities directly proportional to the intensity of the radiation. The meaning of the results is discussed. The square root relationship seems to hold for reactions which are highly photochem. in nature and have a negligible dark reaction.

WILLIAM E. VAUGHAN

**The light reaction between ferric chloride and oxalic acid.** G. KORNFELD AND E. MÜNCKE. *Z. Elektrochem.* 34, 598-601(1928).—The absorbing materials dissociate into 2 parts. These decompn. products give up the energy which they have absorbed in small quantities to H<sub>2</sub>O mols. until they recombine to form the original material. The oxalic acid takes over the energy from H<sub>2</sub>O mols. and reacts with ferric ion forming ferrous ion and CO<sub>2</sub>. It is also assumed that the CO<sub>2</sub> is first activated and then deactivated by coming into contact with ferric ion and excited oxalic acid and finally gives a ferric complex with ferrous salt by which activated CO<sub>2</sub> is again liberated.

HARRY B. WEISER

**Sensitized photolysis.** EMIL BAUR. *Z. Elektrochem.* 34, 595-8(1928).—The theory of the optical sensitization process is: The sensitizer adsorbs a light quantum and becomes an oxidizer-reducer, comparable to the 2 electrodes of an electrolytic cell. The charged electron returns to its original state through a mol. electrolysis. The energy for carrying on this electrolysis will be derived from increase in the potential of the valence electron during the process of light absorption. The consequences of the theory are: (1) similarity between the sensitized photolysis and the correspond-

ing electrolysis; (2) independence of the anode and cathode processes of the sensitized photolysis; (3) independence of a given sensitized photolysis on the nature of the sensitizer; (4) checking of the photolysis by the photolysis product; (5) protection of the sensitizer by the photolysis produced by it. These several points have been illustrated by formulating sp. photochem. reactions.

HARRY B. WEISER

**The photodecomposition of ethyl iodide.** THOMAS IREDALE. *J. Phys. Chem.* 33, 290-5(1929).—The photochem. decompn. of EtI is a simple process, one quantum effecting the detachment of an I atom from 1 mol. This rules out the second postulate of Job and Emschwiller (*C. A.* 18, 3143), the formation and decompn. of HI, unless it is assumed that the energy furnished by the light in excess of that found from thermal measurements is effective for the decompn. As with HI the decompn. of EtI results in the formation of an excited I atom, the excess energy probably being dissipated as kinetic energy through collisions.

HARRY B. WEISER

**The photochemical dissociation of metallic salts dissolved in organic solvents.** E. PUXEDDU. *Gazz. chim. ital.* 59, 160-4(1929).—A preliminary note. Though much work has been done on the disson. of metallic salts in water by light, there is little information on similar phenomena in org. solvents. The action of light on  $\text{FeCl}_3$  in  $\text{Et}_2\text{O}$  has, however, been described by P. (cf. *C. A.* 14, 3368), and the present work is an extension of these earlier expts., the action of light on  $\text{HgCl}_2$ ,  $\text{PbCl}_2$  and  $\text{TiCl}_4$  in anhyd.  $\text{Et}_2\text{O}$  being studied. The solns. were exposed in hermetically sealed bottles to sunlight for long periods. With  $\text{HgCl}_2$ , a grayish white ppt. formed very slowly, 3.2 g. being deposited from 10 g. of  $\text{HgCl}_2$  after nearly 6 months. This ppt. was  $\text{HgCl}$  contg. an org. substance. The  $\text{Et}_2\text{O}$  contained  $\text{HCl}$ , aldehydes and chlorinated compds. The soly. of  $\text{PbCl}_2$  in anhyd.  $\text{Et}_2\text{O}$  is so extremely low that it was impossible to analyze the products of the reaction. With  $\text{TiCl}_4$  (5 g. in 230 g. of  $\text{Et}_2\text{O}$ ), the soln. turned brown during the 2nd day, and ultimately became clear green and remained so indefinitely. On evapn. of the  $\text{Et}_2\text{O}$  at a low temp., the mixt. became violet, suggesting the green and violet modifications of  $\text{TiCl}_3$ . A cryst. compd. could not, however, be obtained from the dry residue. In conjunction with the earlier expts. with  $\text{FeCl}_3$  (*loc. cit.*) the results indicate that exposure of salts of metals with more than one valency to sunlight causes reduction with formation of salts of the metals with a lower valency. C. C. D.

**The photosensitized and photochemical decomposition of hydrazine.** JOSEPH C. ELGIN AND HUGH S. TAYLOR. *J. Am. Chem. Soc.* 51, 2059-82(1929).—The photochem. decompn. of  $\text{NH}_2$  yields higher than a 3 to 1 ratio of  $\text{H}_2$  to  $\text{N}_2$ . E. and T. propose primary formation of  $\text{N}_2\text{H}_4$ . Anhyd. hydrazine was exposed to light from a Cooper-Hewitt arc.  $\text{NH}_3$  increased to 77% of the theoretical then gradually disappeared. The decompn. is apparently unimol., independent of temp., and unaffected by addn. of  $\text{N}_2$ ,  $\text{H}_2$  or  $\text{NH}_3$ . Thermal decompn. begins at  $250^\circ$ , is heterogeneous, unimol., and yields chiefly  $\text{N}_2$  and  $\text{NH}_3$ . Photosensitized decompn. of  $\text{N}_2\text{H}_4$  by excited Hg atoms activated by light of 2537 Å. U. is exceedingly rapid, proportional to the intensity, and unaffected by addn. of  $\text{N}_2$ ,  $\text{NH}_3$  or  $\text{H}_2$ . Deactivation of Hg in the  $2^1P_1$  state by  $\text{H}_2$  must lead to H atoms which can activate the  $\text{N}_2\text{H}_4$ . The quantum efficiency is at least 13 moles per absorbed quantum. The absorption spectrum of gaseous  $\text{N}_2\text{H}_4$  consisting of 6 or 7 probably continuous bands from 2490 to 2260 Å. U. indicates excited mols. subject to spontaneous primary decompn. Considerations of energetics permit 4 mechanisms. Two of these give only short chains and fail to account for non-retardation by  $\text{H}_2$ . Both the sensitized and the photochem. reactions proceed by either of 2 mechanisms: (a)  $\text{N}_2\text{H}_4 \longrightarrow \text{N}_2\text{H}_3 + \text{H}$ ,  $\text{N}_2\text{H}_3 + \text{N}_2\text{H}_4 \longrightarrow 2\text{NH}_3 + \text{N}_2 + \text{H}$ ,  $\text{H} + \text{N}_2\text{H}_4 \longrightarrow \text{N}_2\text{H}_3 + \text{H}_2$ ; and (b)  $\text{N}_2\text{H}_4 \longrightarrow 2\text{NH}_2$ ,  $\text{NH}_2 + \text{N}_2\text{H}_4 \longrightarrow \text{NH}_3 + \text{H}_2 + \text{H}$ ,  $\text{N}_2\text{H}_4 + \text{H} \longrightarrow \text{NH}_3 + \text{NH}_3$ . The chain reactions are broken up by the wall reactions,  $2\text{H} \longrightarrow \text{H}_2$ ,  $2\text{NH}_2 \longrightarrow \text{N}_2\text{H}_4$  and  $\text{N}_2\text{H}_3 + \text{H} \longrightarrow \text{N}_2\text{H}_4$ . E. and T. propose to study the decompn. of methylamine, which has a fine structure in its absorption spectrum.

F. H. RATHMAN

**The hydrogen-chlorine flame.** E. B. LUDLAM, H. G. REID AND G. S. SOUTAR. *Proc. Roy. Soc. Edinburgh* 49, 156-9(1929).—The H-Cl flame was photographed and in addn. to the continuous spectrum a band spectrum was obtained. The continuous spectrum was thought to be due to the recombination of the Cl atoms before reaching any H atoms. The band spectrum was due to the presence of S obtained from the gas-drying train.

F. W. LAIRD

**Effects of irradiation of crude coal tar by quartz mercury vapor lamps. I. Evidence of chemical changes as shown by changes in absorption spectra.** JULIA HERRICK AND CHARLES SHEARD. *Proc. Soc. Exptl. Biol. Med.* 26, 33-40(1928).—Ether solns. of crude coal tar show increased transmissibility to ultra-violet light after irradiation by an air-cooled quartz Hg vapor lamp. Such solns. on standing have a decreased

transmissibility and become more opaque; the opaqueness disappears when irradiated. These phenomena are more marked in thin films of crude tar than in ether solns. The changes in transmissibility are interpreted as chem. changes in the tar produced by the quartz Hg vapor lamp.

C. V. BAILEY

**Integration of light by photoelectrolysis.** W. R. G. ATKINS AND H. H. POOLE. *Sci. Proc. Roy. Dublin Soc.* 19, 159-64(1929).—A Burt Na cell, used for the integration of light, gave 1.15 microamp. per 1000 meter-candles. On a bright November afternoon, it was possible to detect the production of alkali in a dil.  $\text{NaHCO}_3$  soln. within 10 sec. The current may also be used for the deposition of Cu, 0.1 mg. per day being deposited with the photometer sloped in a south window. The K ethylxanthate method for Cu enables one to distinguish between solns. differing in Cu content by 0.002 mg. per 100 cc.

LOUIS WALDBAUER

**Photodichroism and photoanisotropism. I. Fundamental phenomena and definitions.** FRITZ WEIGERT. *Z. physik. Chem., Abt. B*, 3, 377-88(1929).—W. considers at some length exptl. work on the phenomena that light-sensitive solid layers when illuminated with linearly polarized light become dichroic and anisotropic. He treats in particular photographic processes, wherein Ag salts exposed to radiation exhibit these properties. Photodichroism is stronger if there is present an appreciable quantity of Ag at the beginning of the exposure; the effect becomes weaker with shorter wave length; it is strongest in the red. The process is not a simple one, since it involves auto-sensitization; in the visible metallic Ag is the sensitizer while in the ultra-violet a photolysis of AgCl results. Parallel with the dichroism there occurs a color adaptation of the Ag. Primary dichroism is the simplest case; it is development of the dichroism on exposure of the solid layer to light. Secondary dichroism is the change or disappearance of the phenomenon due to photographic manipulations after the primary process. Induced dichroism is a new phenomenon, whereby, in a primary photoanisotropic system new colored constituents with dichroic properties result. This latter is quite complex. Many references are given. **II. The fundamental phenomena of induced dichroism and the experimental methods.** *Ibid* 389-404.—Induced photodichroism and its effects may be secured for study without disturbance by concurrent primary and secondary dichroism or photographic layers if the plates are fixed after sensitization and then colored Ag produced by a phys. developer. This Ag has dichroic characteristics. Measurements were made with a modified Lippich half-shadow dichrometer.  $D$ , the dichroism of the layer under investigation, is given by  $\log I_e/I_m$ , the log of the ratio of intensities in the directions of the elec. and magnetic vectors, or by  $E_m - E_e$ , the difference in the extinctions. For small values of  $2\alpha$  ( $\alpha$  being the angle of rotation of the dichrometer),  $D = \log \tan(45^\circ \pm 2\alpha)$ . The exptl. technic is fully given. The relation of the new effect to photographic, colloid and other problems is discussed.

**Radioactive preparations.** ALOIS FISCHER and GEORG SCHAPRINGER. Austrian 113,435, Jan. 15, 1929. The use of metal or glass containers for radioactive preps. is avoided by mixing the preps. with a binder such as wax or resin, shaping the mixt. into small rods or fibers, coating with graphite, and then coating with metal. Thus, a coating of Cu may be applied followed by a thin coating of Pt.

**Production of light.** VEREINIGTE GLÜHLAMPEN UND ELEKTRICITÄTS-A.-G. Austrian 113,432, Jan. 15, 1929. Gases or vapors the interaction of which is accompanied by chemiluminescence are brought to reaction at a very low pressure, *e. g.*, 0.01-0.1 mm. An enhanced luminescence is so obtained.

## 4—ELECTROCHEMISTRY

COLIN G. FINK

**Inductor coils for the high-frequency furnace.** C. N. SCHUETTE. *Ind. Eng. Chem., Anal. Ed.* 1, 141-4(1929).—Detailed directions for making high-frequency induction-furnace coils from seamless-soft-drawn-copper tubing, and insulating and mounting them for use are given. A coil can be wound, soldered and tested in a day. Insulation takes half a day. While the coil is drying the base and frame may be made, and on the fourth day the new furnace can be in operation. W. C. EBAUGH

**Does the preparation of close-grained electric-furnace cast iron require basic conditions?** K. F. KRAU. *Gieserei* 16, 88-91(1929).—The metallurgical requirements upon which the prepn. of close-grained elec. furnace cast iron depends are briefly reviewed. Inquiry is made as to whether acid elec. furnaces can be justified. Action of Si in acid practice is that of deoxidizer and degassing agent. C. L. MANTELL

**The Soderberg self-baking electrode.** M. SEM. *Can. Chem. Met.* 13, 177-8(1929). Four illus. The method results in a continuous C electrode for large industrial electric furnaces. S. gives detailed, first-hand information with respect to the paste from which the most satisfactory results have been obtained in practice. E. G. R. A.

**Electrolytic production of potassium ferricyanide from potassium ferrocyanide.** I. G. SHCHERBAKOV. *Zhur. Prikladnoi Khim.* 2, 155-65(1929); cf. *C. A.* 20, 551.—The liquid Hg cathode works satisfactorily. The  $K_3Fe(CN)_6$  produced is free from alkalis and  $K_4Fe(CN)_6$ . The anodic process is essentially the same as in electrolysis with solid cathodes. The cathodic process requires higher voltage with liquid than with solid cathode in app. using clay diaphragms. An av. current density of 1.5-2 amp./sq. in at 20-30° is satisfactory for com. work. An increase in current density from 1 to 4 amp./sq. in. results in an increase in potential of 4-6 v. Per kg. of  $K_3Fe(CN)_6$  0.5 kw.-hr is consumed. If electrolysis is continued after all the  $K_4Fe(CN)_6$  is consumed acid salts are formed. V. KALICHEVSKY

**Pressure electrolysis—power and fuel.** J. E. NOEGGERATH. *Proc. 2nd Intern. Conference on Bituminous Coal*, Nov. 1928, 2, 400-12.—Electrolysis of water into  $O_2$  and  $H_2$  under pressure requires less power than does electrolysis at atm. pressure. Discussion of the problem, fundamental laws, application of gases generated at high pressure (150 atm.), description of app. and N.'s cells, cell characteristics and operation with specific application to utilization of high-pressure gases in internal-combustion engines using oils, etc., instead of gasoline, are included in the paper. The power, floor space, safety and economic advantages are stressed, particularly the elimination of gas compressors. C. L. MANTELL

**The development of the oxide-coated filament.** B. HODGSON, L. S. HARLEY AND ( ) S. PRATT. *J. Inst. Elec. Eng.* (London), 67, 762(1929).—See *C. A.* 23, 1824(1929) M. McMAHON

**Dependence of resistance of insulating and other materials on potential and frequency and their resulting phenomena.** Experimental determination of space charges. P. BÖNING. *Z. tech. Physik* 10, 82-93, 118-24(1929); cf. *C. A.* 23, 1795.—B. has made an extensive investigation of the behavior of insulating and other materials on the basis of ion adsorption on inner surface levels, particularly the dependence of resistance on potential. Curves are given showing the specific resistance *vs.* field strength for gypsum crystals, glass, "silit" and cotton. Earlier deductions showed that insulating material was characterized by the fact that the apparent value of its dielec. consts. and its resistance decreased with increasing potential. With d. c. there is a simple expression for this dependence. With a. c. the relation is very complicated; a substitute scheme and simplification is introduced. Results show that the apparent resistance of an insulating material on a. c. must be smaller than on d. c. and that the loss at high frequencies is independent of frequency. Results are given for the exptl. detn. of space charge under the influence of elec. field, to whose existence was attributed the behavior of insulating material. Differences in voltage distribution in a condenser with 2 layers, air and insulating material, were detd. when the space charge is present by means of special app. A more satisfactory space charge effect was obtained by choosing a dielec. with more boundary faces and lower cond.: paraffin with colophony or paraffin and wood-flour. The results uphold the conclusion that adsorbed ions which constitute the space charge are pos. Reference was made to an instability phe-

nomenon and to the influence of temp. on the reaction. A loosening of the structure of the investigated material causes an increase in the reaction; a colloidion coating prevented ion exit.

**Device for maintaining the proper electrolyte level in storage batteries.** J. D. SARTAKOFF. Brit. 302,206, Sept. 9, 1927.

**Galvanic batteries.** G. FERRABINO. Brit. 301,923, Dec. 9, 1927. Mg or a Mg alloy is used for the anode, an aq. soln. of salts such as  $MgCl_2$ ,  $MgSO_4$ , or  $KCl$  is used for the electrolyte together with substances such as sulfites, oxalates, ferrocyanides, chromates, bichromates or Cr salts and alk. hydrates which prevent oxidation of the Mg on open circuit. The cathode comprises a cond. and depolarizing substance such as dioxides of Mn, Pb or Ba; metallic hydroxides, basic Cu sulfate and  $KClO_3$ , also may be used.

**Galvanic batteries with plate electrodes and separating frames embedded in cement.** SIEMENS & HALSKE A.-G. Brit. 301,934, Dec. 9, 1927. Structural features.

**Selenium cell.** HEINRICH KÜCHENMEISTER. Fr. 657,524, July 16, 1928. Constructional details.

**Molded battery box with a transparent window.** PAUL H. HENKEL (to Continental Rubber Works). U. S. 1,720,363, July 9. Structural features.

**Accumulators.** ALBERT J. M. BAILLEUX and ARTHUR F. HILL. Ger. 477,515, Oct. 15, 1927. Construction of casing is given.

**Accumulator plates.** GEORGE F. DOWNER. Ger. 477,627, May 27, 1925. Plates with gratings filled with  $PbO$  are specially treated to prevent loss of the  $PbO$ .

**Accumulator plates.** ADOLFO POUCHAIN. Ger. 477,628, Jan. 11, 1928. The construction of a cathode for Zn accumulators is described.

**Transportable accumulator with spiral electrodes.** DEUTSCHE ELEMENTE FABRIK A.-G. Ger. 478,089, Sept. 20, 1927.

**Semi-solid electric conductor.** HARRY N. MILLER (to Fansteel Products Co.). U. S. 1,720,371, July 9. A compn. suitable for use in electrolytic condensers comprises an electrolyte such as  $NaHCO_3$  incorporated in a gelatin compn. hardened with  $CH_2O$ .

**Cadmium-coated electric conductors.** M. A. BOLTON and J. W. WALKER. Brit. 302,202, Aug. 12, 1927. Cd may be applied to a cond. wire such as Cu or Ag by passing through a bath of metallic Cd or by electrolysis. Other metals such as Sn may be applied under or over the Cd coating and the Cd-coated wire may serve as a bond wire in Pb-sheathed cables or may be insulated by vulcanized rubber, bitumen, etc.

**Rectifier for alternating currents.** E. PRESSER (to Süddeutsche Telefon-Apparate, Kabel-und Drahtwerke A.-G.). Brit. 302,177, Dec. 10, 1927. In making rectifiers comprising a layer of Se or a Se compd. fused, electrolytically deposited or otherwise intimately united with one of a pair of metal electrodes between which the layer is placed, the electrode carrying this layer is heated to between  $80^\circ$  and the m. p. of Se (preferably at least  $175^\circ$ ) to convert the Se from the amorphous to the metallic state without destroying the intimate union of the layer with the electrode.

**Cuprous oxide rectifiers.** SIEMENS-SCHUCKERTWERKE A.-G. Brit. 301,728, Dec. 3, 1927. In the prepn. of plates of  $Cu_2O$  rectifiers, the plates are heated to a temp. above the dissocn. temp. of the Cu oxide (suitably to about  $1025^\circ$  at ordinary atm. pressure).

**Mercury-vapor rectifiers.** WESTINGHOUSE ELECTRIC & MANUFACTURING CO. Fr. 656,958, July 3, 1928.

**Rectifying alternating currents.** E. PRESSER (to Süddeutsche Telefonapparate Kabel und Drahtwerke A.-G.). Brit. 301,839, Dec. 6, 1927. Se or its compds. serve as the rectifying layer between metal electrodes, or the layer may be formed by fusing or electrolytically depositing it on one of the electrodes, or one of the electrodes may be formed of metal of high at. wt. such as Pb or Bi mech. pressed against the rectifying layer. A high degree of asymmetry in the conducting properties of dry rectifiers is secured by any of these constructions. The surface of the electrode with which the layer is intimately connected is preferably made of or coated with Fe, Ni, Co, Cr or Mn; or, an alloy of Cr and Fe may be used with another electrode of Pb or Bi.

**Forming metal panels with inlaid designs by electro-deposition of metals.** A. M. CALLOW. Brit. 302,636, Sept. 19, 1927. Various details of procedure are given. The foundation plate may be formed of Ag-plated Cu or other material covered with Pb and the use of celluloid inlays is also described, which may be covered with cond. material and then with electrodeposited metal.

**Apparatus for electrodeposition of chromium on the inside of hollow articles.** KEVIN W. SCHWARTZ (to Chromium Corp. of America). U. S. 1,720,354, July 9. Structural features.

**Anode for chromium plating.** FREDERICK M. BECKET. U. S. 1,720,312, July 9. Cast anodes are used comprising Cr together with 0.5–7.0% C. U. S. 1,720,313 specifies the use of an electrolyte formed mainly of an aq. chromic acid soln., with a substantially C-free anode comprising Cr together with 0.25–35% Si.

**Electrolysis.** BAMAG-MEGUIN A.-G. Fr. 656,833, June 29, 1928. In electrolysis, particularly in the decompn. of water, diaphragms composed of asbestos threads with a metallic coating are used.

**Apparatus for electrolysis of fused chlorides.** I. G. FARBENIND. A.-G. Brit. 302,881, Dec. 23, 1927. In an app. for electrolysis of  $MgCl_2$  or other fused chlorides, the partitions for sepg. the products are faced with ceramic material such as porcelain plates or may be made of ceramic material.

**Electrolytic cells suitable for producing caustic soda, chlorine and hydrogen, etc.** FRANK H. BUCK and PHILIP MCRAE (to Jessup & Moore Paper Co.). U. S. 1,720,995–6, July 16. Structural features.

**Electrolytic sharpening of tools such as files.** WALTEN B. ROBE (to Rekeen Tool Co.). U. S. 1,721,414, July 16. An elec. current is passed to tools such as files, rasps or dental burrs from an electrode through a soln. formed from  $CuSO_4$ ,  $H_2SO_4$ , borax and  $HOAc$ .

**Electrolytic fat removing.** RIEDEL & CO. FABRIK FÜR CHEM.-TECHN. ERZUGNISSE. Ger. 478,362, Dec. 24, 1927. In the electrolytic fat-removing process means for keeping the surface of the bath free from foam and fat at the part where the bodies under treatment are removed is described.

**Aluminum.** PAUL L. HULIN. Fr. 656,503, Nov. 9, 1927. In purifying Al electrolytically the anode is composed of an alloy of Al having a f. p. lower than that of pure Al, the alloying metal being much more electropos. than Al. The electrolyte is composed of halogen compds. of the same kind, the mixt. having a f. p. lower than that of pure Al. The electrolysis is carried out at a temp. above the f. p. of the anode alloy but below that of the pure Al deposited at the cathode.

**Aluminum-silicon alloys.** RICHARD MÖLLER. Ger. 478,075, July 17, 1925. Al-Si alloys are prepd. by addn. of elementary Si in the required amt. to the fluoride melts ordinarily used in the electrolytic manuf. of Al.

**Working up anode sludge from the electrolytic manufacture of tin.** FIRMA JACOB NEURATH. (Theodor Kittl, inventor). Austrian 113,317, Jan. 15, 1929. Addn. to 102,289. The anode sludge obtained in the process of Austrian 102,289 (see Brit. 240,147; C. A. 20, 2126) is treated with hot  $HCl$ , allowed to weather for a month or more, and then treated again with  $HCl$ . In this way the sludge is rendered completely sol. except for  $PbCl_2$ , which is removed. The soln. may then be treated with Fe to ppt. Cu and Sb, and the ppt. may be weathered again to form basic  $CuCO_3$ , and then treated with  $H_2SO_4$  to sep. the Cu from the Sb.

**Calcium carbide and pig iron.** HILLIARY ELDRIDGE. U. S. 1,719,970, July 9. A mixt. of  $CaCO_3$ , C and iron oxide is subjected to the action of an elec. arc by which CO and  $CO_2$  are evolved and a current of air is injected into the gases above the treated mass and in a direction away from it for effecting combustion and producing suction above the mixt. An app. is described.

**Ore treatment.** BERGBAU- U. HÜTTEN A.-G. Ger. 477,888, May 18, 1926. Fine ores, carbonates and similar substances are agglomerated by mixing with Fe filings and subjecting to an elec. current.

**Apparatus for sterilizing water electrically.** MARIUS P. OTTO. Fr. 656,502, Nov. 9, 1927.

**Filter-press electrolyzer suitable for decomposing water, etc.** RODOLPHE PRCH-KRANZ. U. S. 1,721,407, July 16. Structural features.

**Treating gases and vapors electrically.** I. G. FARBENIND. A.-G. Fr. 657,441, July 12, 1928. For treating gases or vapors by high-tension elec. currents in the form of discharges called "dark," solid or liquid insulating substances such as glass beads are introduced into the reaction spaces.

**Electrical purification of gases.** OSKI-A.-G. (Heinrich Bernhard R., inventor). Ger. 478,034, Feb. 25, 1928. In the treatment of hot gases in a horizontal elec. cleaner, the cold gases accumulating in the bottom of the cleaner are continuously withdrawn and added to the ingoing gases. This may be effected by ejector action.

**Electrical purification of gases.** OSKI-A.-G. (Erich Oppen, inventor). Ger. 478,309, Apr. 30, 1924. In the elec. cleaning of combustible gases or gases carrying

impurities liable to explode, the gases are led up to the cleaning app. at such a velocity that a flame, if produced in the cleaning app., cannot strike back. The gases are passed through the cleaner at a lower velocity suitable for the cleaning. Cf. C. A. 23, 2893.

**Electric gas cleaner.** METALLGES. A.-G. (Fritz Lechler, inventor). Ger. 478,454, Nov. 22, 1925.

**Electric cleaner for gases and insulating liquids.** HERTHA MÖLLER NÉE WEBER, ARNOLD LUYKEN, GERTRUD LUYKEN, ERNST LUYKEN, NORA LAMPING NÉE MÖLLER, ILSE VOGG-CASTENDYK, IRMGARD FREUDE NÉE CASTENDYK, FRITZ K. CASTENDYK, HENDRICH LUYKEN, GERDA LUYKEN, ELISABETH LUYKEN AND JOHANN LUYKEN. Ger. 478,478, Sept. 13, 1921. Addn. to 443,672.

**Electric gas cleaner (with condenser in parallel with the electrodes).** OSKI-A.-G. (Erich Oppen, inventor). Ger. 478,386, Oct. 4, 1925.

**Precipitating electrode for electric gas cleaners.** SIEMENS-SCHUCKERTWERKE A.-G. Ger. 478,377, May 27, 1925.

**Deoxidizing air in electric apparatus.** LELAND H. HILL and WALTER M. DANN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,720,516, July 9. Liquid-insulated elec. app. such as transformers or interrupters contg. oil is provided with means for effecting air circulation in the app. above the liquid level and for absorbing the O in the air. Various structural features are described.

**Apparatus for drying air for electrical transformers by use of desiccating agents.** ALLMÄNNNA SVENSKA ELEKTRISKA AKTIEBOLAGET. Brit. 302,071, Jan. 4, 1928. Structural features.

**Promoting chemical reactions, separating dust from gases, etc., by an oscillating magnetic field.** A. ESAU AND C. LORENZ A.-G. Brit. 301,929, Dec. 8, 1927. An oscillating magnetic or elec. field of a wave length of 10 meters or less is utilized. Brit. 301,930 relates to a similar process.

**Apparatus for electrometric testing or composition control of liquids.** H. D. HATFIELD. Brit. 302,490, Dec. 5, 1927. Various structural and electrical features are described.

**Electric furnace.** E. BORNAND and H. A. SCHLAEFFER. Brit. 301,912, Dec. 8, 1927. A furnace stated to be suitable for the production of alloys of Mg and Al and for deoxidizing iron by use of metallic oxides, or other operations in which materials are treated, one of which is lighter than another, is provided with an electrode adjustable vertically in such a manner as to force portions of the lighter material into the heavier material. Various structural details are described.

**Electric furnace for metal fusing.** EDWARD R. STOEVE. Fr. 656,736, Nov. 9, 1927.

**Electric induction furnace.** E. F. NORTHRUP. Brit. 301,954, Sept. 8, 1927. Structural features.

**Electric induction furnace.** SIEMENS & HALSKE A.-G. Brit. 301,894, Dec. 8, 1927. An "ironless" furnace employs coils of solid material such as Cu bands in an insulating liquid such as circulating oil. The app. is suitable for annealing wire.

**Electric induction furnace for melting metals.** J. HÄRDEN. Brit. 302,308, Dec. 14, 1927.

**High-frequency induction crucible furnace.** WILHELM ESMARCH (to Siemens & Halske, A.-G.). U. S. 1,721,073, July 16. Structural features.

**Electric resistance furnace.** SIEMENS-SCHUCKERTWERKE A.-G. Brit. 302,223, Dec. 12, 1927.

**Electric resistance furnace.** CARL L. IPSEN and ALBERT N. OTIS (to General Electric Co.). U. S. 1,719,888, July 9. Structural features.

**Electric resistance heater suitable for convection heating.** WALTER C. CALCOTT (to Schleicher, Inc.). U. S. 1,719,872, July 9. Structural features.

**Tapping electrode construction and associated features for electric furnaces.** SIEMENS & HALSKE A.-G. Brit. 302,305, Dec. 14, 1927.

**Electrode mounting for electric furnaces.** ERNST WIRZ (to A.-G. Brown, Boveri & Cie.). U. S. 1,719,863, July 9.

**Carbon electrodes suitable for fusion electrolysis.** I. G. FARBENIND. A.-G. Brit. 302,891, Dec. 23, 1927. C electrodes are soaked in or coated with phosphoric acid to protect them from the atm.

**Oxide cathodes.** GUSTAV L. HERTZ (to N. V. Philips Gloeilampenfabrieken). U. S. 1,720,675, July 16. Material such as Pt or Mo or Ni-Cr coated with Cu oxide is coated with an alk. earth metal such as Ba and the coated material is heated in a non-oxidizing atm. to melt the alk. earth metal layer and the latter is at least partly oxidized.

**Oxide cathodes.** KAREL M. VAN GESSEL (to Radio Corp. of America). U. S. 1,721,169, July 16. A core of W, Mo or other suitable refractory metal or alloy which does not readily form an alloy with any of the alk. earth metals is coated with a film of a readily oxidizable metal such as Cu having a comparatively low point of volatilization, the film is at least partially oxidized and the oxidized film is coated with one or more of the alk. earth metals by bringing the film into contact with the vapor of the alk. metal and effecting pptn. of the latter; the product is then heated to convert the alk. earth metal into oxide and to volatilize the Cu. Cf. C. A. 23, 1018.

**Nickel anodes.** THE INTERNATIONAL NICKEL CO. Fr. 656,475, June 26, 1928. Oxides of metals of the Ni group are uniformly distributed throughout a mass of Ni in amt. of 0.5-0.25% of the wt. of Ni, the resulting compd. being electrolytically non-passive.

**Electric ozone generator and control system for operating the apparatus at intervals.** C. J. V. FERVY. Brit. 301,883, Dec. 7, 1927.

**Piezoelectric and pyroelectric materials.** TELEFUNKEN GES. FÜR DRAHTLOSE TELEGRAPHIE. Brit. 302,726, Dec. 21, 1927. Finely divided material such as quartz powder is subjected to an elec. field to cause the particles to take up a definite direction with respect to their elec. moments and the particles are bound together by strong heating and high pressure or with a binder such as paraffin.

**Conversion of calorific energy into electrical energy.** F. DUVIEUSART. Belg. 352,184, Dec. 31, 1928. The process consists in polarizing osmotic cells consisting of membranes impregnated with solns. or which can absorb gases.

**Metallic powders.** SOC. ANON. DES TRÉFILIERIES ET LAMINOIRS DU HAVRE Fr. 656,777, Nov. 16, 1927. Very fine metallic powders are obtained electrolytically by adding a carbonized material in the dispersed state to the bath. Thus, a fine Cu is obtained by adding glucose treated with H<sub>2</sub>SO<sub>4</sub> or sugar-C as an impalpable powder to an electrolyte consisting of a H<sub>2</sub>SO<sub>4</sub> soln. of CuSO<sub>4</sub>.

**Metal-vapor lamps.** HANNS STAMMREICH. Fr. 657,426, July 11, 1928. An alloy of Hg with another metal such as Cd is used in the lamp, the Hg being distd. off first to a sep. compartment which is then closed before the other metal begins to vaporize. The Hg is afterward run back by tilting the lamp.

**Mercury-vapor lamps.** ALEXANDRE MOSINSKI. Fr. 656,631, June 28, 1928. Method of fixing electrodes.

**Electric discharge devices.** SIEMENS & HALSKE A.-G. Brit. 302,583, Dec. 17, 1927. Cathodes of devices such as rectifiers filled with rare gases or Hg vapor are formed by the deposition of rare earth metals such as La, Ce, Yb or Yt or other electron-emitting metals such as Zr on a base of refractory metal such as W or Mo. The active layer may be mixed with Th and may be deposited electrolytically or in other manner which precludes oxidation, as by deposition of Ce *in vacuo* from its vapor or by reducing Ce nitrate with Mg. Cf. C. A. 23, 1019.

**Electric discharge lamp.** L. L. BECK (to Claude Neon Lights, Inc.). Brit. 302,643, Dec. 19, 1927. A lamp giving light from the pos. column contains Hg and a mixt. of rare gases such as A which produces light of a color similar to that produced by Hg, a heat-producing gas such as He and a diluent such as Ne. The light remains constant at low external temps. Brit. 302,668-9 also relate to similar lamps.

**Electric discharge lamps.** PATENT TREUHAND GES. FÜR ELEKTRISCHE GLÜH-LAMPEN. Brit. 302,701, Dec. 20, 1927. Lighting tubes are divided by longitudinal partitions into chambers which are filled with different gases or vapors to produce various lighting effects depending on which chambers are connected in the circuit; e. g., one chamber may contain a mixt. of A and Hg, with or without Ne, another chamber Ne and still another N or CO<sub>2</sub>. Various structural details are described.

**Electric vacuum discharge tubes.** M-O VALVE CO., LTD. and J. W. RYDE. Brit. 302,503, Dec. 23, 1927. In making cathodes, a metal support such as W has deposited on it a highly electropositive metal such as an alkali or alk. earth metal, after treatment with CN. Various details of temps., pressures, etc., are described.

**Incandescent discharge cathodes.** N. V. PHILIP'S GLOEILAMPENFABRIEKEN. Fr. 657,054, June 7, 1927. The cathodes are made of salts of energetically electropos. metals, in particular alkali and alk. earth metals having amphoteric oxides which are less acid than titanous acid. Cf. C. A. 23, 2668.

**Incandescent cathode tubes.** N. V. PHILIP'S GLOEILAMPENFABRIEKEN. Fr. 656,819, June 29, 1928.

**Electric-lighting tubes.** PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜH-LAMPEN M. B. H. (Franz Skaupy and Hans Pulfrich, inventors). Ger. 478,073, Nov.

5, 1926. Elec.-lighting tubes are filled with a mixt. of  $\text{CO}_2$  and an inert gas, especially He, the latter preferably predominating

**Electric incandescent lamps.** J. A. KLOKS. Brit. 301,709, May 26, 1928. P trioxide is introduced with a gas filling which may be prepd. by passing inert gas mixed with a very small proportion of O through liquid P.

**Gas-filled electric incandescent lamp.** GORTON R. FONDA (to General Elec. Co.). U. S. 1,721,384, July 16. In order to prevent damage by arcing in case of burned-out filaments, a hollow section of the supply wires in an incandescent lamp is provided with arc-quenching materials such as sulfates of Cu and Ni, a nitrate of Ni, Cu, Na or Ba or, in some instances, Fe sulfate or  $\text{BaSO}_4$ .

**Tungsten composition suitable for incandescent lamp filaments.** GORTON R. FONDA (to General Elec. Co.). U. S. 1,721,383, July 16. A compn. which has long life and high-lighting efficiency consists mainly of W and also contains less than 1% of Th oxide and B nitride.

**Filaments manufactured from tungsten, molybdenum and other difficultly fusible metals at a temperature below 1000°.** KARL W. ZSCHOCKE. Austrian 113,453, Jan. 15, 1929. Mech. and manipulative features are given.

**Vibration- and sag-resistant filament.** JOHN H. RAMAGE (to Westinghouse Lamp Co.). U. S. 1,720,000, July 9. A filament free from sagging and offsetting and which is resistant to shock and vibration is prepd. by heating a solid-soln. alloy of W and Ta under oxidizing conditions to convert the Ta into oxide, and producing filaments from the resulting product.

## 5—PHOTOGRAPHY

C. E. K. MEES

**Progress in photography in the last ten years.** J. EGGERT AND H. MEDIGER. *Z. angew. Chem.* 42, 700-3(1929). E. H.

**Photochemistry of silver halide.** V. Silver values and the fixing process. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* 26, 375-80(1929); cf. *C. A.* 23, 2669.—In all investigated cases, the amt. of free Ag present in the emulsion after fixing is different from the amt. of free Ag present before fixing. In most cases of normal coated plates the amt. was smaller because of the dissolving of free Ag in the fixing bath. The formation of  $\text{Ag}_2\text{S}$  could not be detd. The method of washing of a photographic emulsion has great influence on the Ag values. The present methods of fixation are not suitable for the sepn. of Ag from Ag halide, for high-precision Ag detn.

A. P. H. TRIVELLI  
**Methods and applications of photomicrography.** E. P. WIGHTMAN AND A. P. H. TRIVELLI. *Cuir tech.* 18, 25-36(1929).—A review. J. G. NIEDERCORN

**Light standard for sensitometry and the Davis-Gibson light filter with copper cobalt solutions.** J. M. EDER. *Z. wiss. Phot.* 26, 373-4(1929).—If cobalt ammonium sulfate is not available for use in the Davis-Gibson light filter, E. recommends its prepn. by mixing its components in equiv. quantities. He defends this filter against criticism.

A. P. H. TRIVELLI  
**Magnesium light as a normal light for photographic sensitometry and its relation to the International Standard of Sunlight.** J. M. EDER. *Z. physik. Chem., Abt. A*, 141, 321-30; *Z. wiss. Phot.* 26, 353-62(1929).—E. recommends filtered Mg light for the sensitometry of photographic negative material. The color temp. of the light source can be regulated according to the decision, which was limited to negative material, of the Intern. Congress of Photography, London, 1928. In this way a uniform light standard for the sensitometry of all photographic material can be established.

A. P. H. TRIVELLI  
**Sensitizers and dyes suitable for bleach-out processes.** M. MUDROVČIČ. *Z. wiss. Phot.* 26, 171-92(1928).—M. investigated 44 sensitizers, mostly in 2% alc. or  $\text{H}_2\text{O}$  soln., for use in the bleach-out process of color photography. The best sensitizer was allyldiethylthiourea, already previously mentioned by A. Just (*C. A.* 7, 2519). The best dye for blue was Capri blue GON (Leonhardt); for red, Rosindulin 2B (Kalle); and for yellow, Flavindulin was dissolved in collodion with acetylthiosinamine and coated on glass. Over this was coated a gelatin layer contg. the other two dyes, Rosindulin and Capri blue, and the sensitizer allyldiethylthiourea.

A. P. H. TRIVELLI  
**Mercuric cyanide as a desensitizer.** H. MEYER AND R. WALTER. *Z. wiss. Phot.* 26, 165-70(1928); *Brit. J. Phot.* 75, 692-3(1928).—M. and W. have shown that  $\text{Hg}(\text{CN})_2$  in the form of  $\text{K}_2\text{Hg}(\text{CN})_4$  in soln. with all developers (pyro excepted) is stable

and forms a useful desensitizer in practice. This developer acts as an oxidizer for colloidal Ag and this is regarded as the cause of its desensitizing action. A. P. H. T.

**Influence of carboxyl and carbonyl groups on the developing functions.** A. AND L. LUMIÈRE AND A. SEYEWETZ. *Chimie & industrie Special No.*, 511-2 (Feb., 1929); cf. *C. A.* 23, 2112.—L. and L. and S. have previously shown (*Bull. soc. franc. phot.* 415 (1897)) that a CO group bound to an aliphatic or an aromatic nucleus does not destroy the developing properties of polyphenols, but that these properties are destroyed when 1 or more OH groups are introduced into the aromatic nucleus bound to the CO; e. g.,  $\text{MeCOC}_6\text{H}_4(\text{OH})_3$  and  $\text{PhCOC}_6\text{H}_4(\text{OH})_3$  are developers, whereas  $\text{HOC}_6\text{H}_4\text{COC}_6\text{H}_4(\text{OH})_3$  and  $(\text{OH})_3\text{C}_6\text{H}_4\text{CO}$  are not. It is now suggested that Homolka's explanation (*C. A.* 15, 33) as regards  $\text{CO}_2\text{H}$  groups can also be applied in the case of CO bound to a phenol, it being supposed that, in presence of alkali, there is formed an anhydride between the OH's of the 2 nuclei, one of which has its acidity reinforced by the presence of the CO. When a 2nd CO is substituted in *o*-position to the 1st in polyphenols and aminophenols the developing properties are destroyed. Homolka's hypothesis can also be applied in this case by supposing that, under the action of alkalis, a double anhydride formation takes place, corresponding to each of the 'CO groups, when there are several OH's in the 2 nuclei, so that no developing function remains after dehydration; moreover, the diketone functions of anthraquinone tend to act as oxidizers by absorbing H, resulting in a reaction which is the reverse of developing. When OH's are present in only 1 nucleus, anhydride formation is not possible; but it can be supposed that the absence of developing properties is due to the diketone group which acts as oxidizing agent.

A. PAPINEAU-COUTURE

**Chemistry of Photography Including Developing, Fixing, Toning, Reduction, Intensification.** St. Louis and New York: Mallinckrodt Chem. Works. 65 pp.

**Photography.** I. G. FARBENIND. A.-G. Fr. 656,569, June 27, 1928. Protective layers against halo, particularly for panchromatic materials, are obtained by depositing on one or both faces of the support one or more layers of colloids which take the dyes used to prevent the formation of halo. The dyes used are such as are decolorized in the usual treating baths and have detd. spectral relations between themselves.

**Color photography.** SERGE DE PROCOUDINE-GORSKY. Fr. 656,562, June 27, 1928. See *Brit.* 293,038 (*C. A.* 23, 1359).

**Color photography.** JEAN MEUGNIOT. Fr. 656,769, Nov. 16, 1927. Juxtaposed 3 color screens are obtained by using 3 solid elementary colors (yellow, red, blue or green, orange, violet) sol. in the same solvent which is also a solvent for the support used. The support (gelatin or celluloid) is impregnated with the solvent, and the colors carefully powd. and mixed are sprinkled on the support so that each begins to dissolve and produces a circular colored spot which spreads. When the spots are sufficiently spread the support is dried rapidly. The support may then be varnished and its ready to receive a panchromatic photographic emulsion.

**Photographing transparent objects.** C. G. RÖDER G. M. B. H. Ger. 478,059, Sept. 4, 1928. For the usual preliminary spray-coating to avoid reflection or refraction effects, there is used a soln. of wax in turpentine of such a concn. as to produce a transparent coating of wax.

**Photographic diazotype process.** KALLE & Co. A.-G. *Brit.* 302,184, Dec. 10, 1927. Diazo compds. of aminonaphtholcarboxylic acids in acid, neutral or alk. conditions are used in prep. light-sensitive layers on paper, cellulose film or other supports. If negative pictures are desired, layers in the acid condition are subjected to a short treatment with  $\text{NH}_3$  gas before exposure to light. Metal salts may be included in the layers or applied to the finished pictures to improve the tint and stability of the pictures, and the stability of the layer may also be increased by including in the layers gelatin or a stabilizing agent such as naphthalenetrisulfonic acid, toluenesulfonic acid,  $\text{H}_3\text{BO}_3$ , tartaric acid,  $\text{Na}_2\text{PO}_4$  or thiosulfate. Cf. *C. A.* 23, 2670.

**Method for the production of negatives, positives and printing molds of correct color values in photomechanical reproduction.** DRESDENER ETIQUETTEN-FABRIK SCHUPP & NIERTH A.-G. Ger. 477,808, Feb. 3, 1927.

**Photographic developing.** SOC. DE PHOTOCHIMIE "ELKA." Ger. 478,233, Mar. 5, 1926. See *Brit.* 265,630 (*C. A.* 22, 548).

**Photographic sensitive material.** A. HAMBURGER. *Brit.* 301,962, Sept. 10, 1927. Sensitivity of Ag salts is increased by bathing the emulsioned plate or film, before

exposure, or by treating the emulsion before coating, in a soln. of a double salt of Ag and an alkali with B in the neg. radical, *e. g.*, a salt prepd. from  $\text{AgNO}_3$  and borax. Sensitizing dyes also may be used.

**Photographic sensitive materials.** G. KÖGEL. Brit. 302,282, Dec. 13, 1927. In forming sensitive layers for producing positive prints from negatives, a ferric compd. such as ferric ammonium citrate, tartrate or oxalate is used with a carbonyl compd. capable of reacting with ferrous salts to form colored compds. such as isonitrosoacetylacetone, isonitrosopropionylacetone or nitroso- $\beta$ -naphthol or  $\beta$ -naphthoquinonesulfonic acid. A Ag compd. may be added for producing sepia prints.

**Sensitized paper for the production of photographic proofs imitating crayon or pastel.** F. BUYLÉ. Belg. 355,872, Dec. 31, 1929. A base paper is coated with adhesive and then covered with sand, glass, kaolin, chalk or other finely divided substance; the paper is then sensitized.

**Photographic films.** LOUIS WESTON. Fr. 656,953, July 3, 1928. See Brit. 293,269 (C. A. 23, 1579).

**Thin photographic films sensitized throughout their material.** SOC. INDUSTRIELLE D'APPLICATIONS PHOTOGRAPHIQUES SOC. ANON. Brit. 301,879, Dec. 7, 1927. Cellulose films of a thickness of 0.02–0.06 mm. may be sensitized by the so-called oxalid process by use of diazoic compds. and phenol and developed with  $\text{NH}_3$  or other suitable vapor.

**Film for lenticular-screen color photography.** RODOLPHE BERTHON (to Soc. Civile pour l'étude de la photographie et de la cinematographie au couleurs). U. S. 1,721,244, July 16. One face of a transparent support such as gelatin, celluloid, cellulose or colophony is provided with a backing layer such as celluloid having on its outer surface a multitude of microscopic refracting elements for color-selection purposes. The other face of the support is provided with a layer of material in adhesive form such as a cellulosic compn. which is pervious to gas and is impregnated with a light-sensitive mixt. of a diazo compd. and a phenol which react to form a dark-colored substance when exposed to an alk. atm. such as one contg.  $\text{NH}_3$ . Cf. C. A. 23, 1579.

**Optical system for reproduction of color record photographic images made on lenticular films.** SOC. CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS (to Soc. française cinechromatique procedes R. Berthon). Brit. 301,732, Dec. 3, 1927.

**Noninflammable cellulosic films.** SOC. INDUSTRIELLE D'APPLICATIONS PHOTOGRAPHIQUES SOC. ANON. Brit. 301,878, Dec. 7, 1927. Films of regenerated cellulose are impregnated with aq. solns. of incombustible substances in such proportion that no efflorescence or other injurious action occurs.  $\text{NH}_4$  sulfate, phosphate or chloride may be used, with or without glycerol as a softener of the film. The film may be sensitized with diazo compds. and phenol and developed by  $\text{NH}_3$  or other vapors.

**Production of microscopic diffraction elements on color-cinematograph films.** SOC. CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS. Ger. 477,541, Jan. 28, 1927.

**Photographic prints.** ÉTABLISSEMENTS EDOUARD BELIN. Fr. 657,296, Oct. 28, 1927. Photographic prints are rapidly developed by projecting the ordinary baths on to the emulsion, preferably with vaporization and at a high temp. Cf. C. A. 23, 3866.

**Photographic prints.** RUDOLF FRITSCHÉ. Fr. 656,962, July 3, 1928. See Can. 283,344 (C. A. 22, 4073).

**Photographic prints from documents, etc.** E. TAL. Brit. 301,869, Dec. 7, 1927. Contact printing is effected by use as an illuminant of a surface coated with luminescent matter previously excited by exposure to light and placed in contact with the document or with the back of a sensitive plate used.

**Coloring blue prints.** RUDOLF FRITSCHÉ. Ger. 478,009, May 10, 1928. Blue prints are colored green with a soln. contg. a salt of U, with or without  $\text{K}_3\text{Fe}(\text{CN})_6$  and an org. acid.

**Photomechanical printing surfaces.** MEISENBACH, RIFFARTH & Co., A.-G. Brit. 302,887, Dec. 23, 1927. In producing negatives or screen positives with corrected color values, as for offset printing, an emulsion or wet plate is used which is treated with a hygroscopic substance such as glycerol, so that partial etching can be effected while the plate is in moist condition. Various details of treatment are described.

## 6—INORGANIC CHEMISTRY

A. R. MIDDLETON

A chronological review of books on inorganic chemistry. JAN ZAWIDZKI. *Przemysl Chem.* 13, 204-6(1929).

A. C. ZACHLIN

Valence theory of boron and the constitution of the simplest boron hydride. ERICH MÜLLER. *Z. anorg. allgem. Chem.* 176, 205-8(1928); cf. *C. A.* 20, 2625.—M. questions Wiberg's theory (*C. A.* 23, 2897) on the valency relations of  *diborane* ( $B_2H_6$ ). According to W., 2 of the H atoms hold their 2 electrons jointly with the 2 B atoms, 2 electrons thus revolving about 4 atoms. Each B atom therefore possesses 8 electrons. M. advances the theory that a B atom possesses 2 inner and 3 outer electrons, and if 2 atoms unite to form a doublet, 2 inner electrons can be held jointly, the 2 remaining being available for the outer shell. The inner electrons being designated by x and the outer electrons by dots, the B atom could be indicated thus:  $\cdot xBx\cdot$ , and the formation of a doublet thus:  $\cdot xBx\cdot + \cdot xBx\cdot \longrightarrow \cdot BxxB\cdot$ . The formation of a doublet might occur without use of the inner electrons as follows:  $\cdot \overset{x}{B} \cdot \cdot \overset{x}{B} \cdot$  and  $\cdot \overset{x}{B} : : \overset{x}{B} \cdot$ . The

transformation from one type of doublet to the other  $\cdot BxxB\cdot \rightleftharpoons \cdot \overset{x}{B} \cdot \cdot \overset{x}{B} \cdot$  is the cause for the variation in valency between 3 and 4. Many elements of high at. no. exhibit this same elasticity in the stable form of the outer electron shell, the M shell in Mn or Fe being stable with either 13 or 14 electrons.

H. STOERTZ

Studies on tetrathionates. II. Strontium tetrathionate. R. PORTILLO. *Anales soc. españ. fis. quim.* 27, 351-7(1929); cf. *C. A.* 23, 3416.— $SrS_4O_6$ , obtained by the reaction of I on  $SrS_2O_8$ , has the compn.  $SrS_4O_6 \cdot 6H_2O$  after recrystn. from a mixt. of alc and  $Et_2O$ . It is rather stable in the air, loses  $4H_2O$  *in vacuo* over  $H_2SO_4$ , but the other  $2H_2O$  mols. are not removed with decompn., even on heating to 70-80°.  $SrS_4O_6 \cdot 6H_2O$   $d_{40}^{25} = 2.148$ ,  $SrS_4O_6 \cdot 2H_2O$   $d_{40}^{25} = 2.480$ , soly. 0° 20%, 18° 26.3%, 30° 39%, mol. heat of soln.,  $t^\circ = 17^\circ$ , mol.  $H_2O = 1,000$ ,  $Q = -11.6$ .

E. M. SYMMES

Studies on the nitrites. II. The ammines of nickel nitrite. L. LE BOUCHER. *Anales soc. españ. fis. quim.* 27, 358-67(1929).—A new method of prepn. of red  $Ni(NO_2)_2 \cdot 4NH_3$  is from the pyridinate in which pyridine is replaced by  $NH_3$ . The tetrammine d. = 1.826.  $Ni(NO_2)_2 \cdot 4NH_3$  fixes 2 mols. of  $NH_3$ , giving the violet hexammine. The  $NH_3$  pressure of this compd. has been detd. at temps. between 15° and 115°. The pentammine described by Ephraim is a mixt. of tetra- and hexammine. The red hexammine loses 2 mols of  $NH_3$  when heated to 120° in a current of dry air, leaving a green compd. Heating to drive off  $NH_3$  does not leave the nitrite, but a decompn. product remains.

E. M. SYMMES

Thio salts. VIII. Persulfates. L. FERNANDES. *Atti accad. Lincei* [6], 9, 409-14(1929); cf. *C. A.* 23, 1586.— $HMoS_4$  was prepd. in a new way from normal  $(NH_4)_2MoS_4$  by satg. with  $H_2S$ . The structure  $S_3Mo-S-S-S-NH_4$  is improbable, as the compd. is very stable; also  $H_2S$  could not act as an oxidizing agent to give  $Mo^{VII}$ .  $HCl$  at 40-45° decomps.  $HMoS_4$  into  $MoS_3$ , S and  $H_2S$ ; so the compn. is probably like the alkali polysulfides, *i. e.*  $[Mo_2S_7(S_6)](NH_4)_2$ . The V salt is formed in a similar manner:  $V_2S_5 + 2(NH_4)_2S_2 = (NH_4)_4V_2S_9$ ; the ratio of  $S_{(NH_4)_2S} : S_{V_2S_5} : S_{free} = 2:5:2$  gives a structure  $[V_2S_7S_9]^{S_2}(NH_4)_4$ . Guanidine persulfomolybdate was prepd. by leaving a soln. of  $(NH_4)_2MoS_4$  satd. with  $H_2S$  in contact with guanidine chloride. Guanidine persulfovanadate is formed in a similar manner. The K and TI salts are obtained by digesting the above with  $TiNO_3$  or  $KCl$ , resp.

A. W. CONTERI

The double carbonate of cobalt and potassium. F. DE CARLI. *Atti accad. Lincei* [6], 9, 417-9(1929).—When  $Co(NO_3)_2$  is added to a warm concd. soln. of  $K_2CO_3$  a reddish soln. is obtained from which  $CoCO_3 \cdot K_2CO_3 \cdot 4H_2O$  crystallizes. The isotherms of dehydration at 100° and 120° have been measured. After 7 $\frac{1}{4}$  hr. at 120° the dehydration is complete. The curve of partial pressure of  $CO_2$  against  $T^\circ$  abs. gives 13.74 as sum of the heat of disson. of  $CoCO_3$  and the heat of decompn. of  $CoCO_3 \cdot K_2CO_3$ ; the latter has been detd. calorimetrically as + 5.76 cal. (*C. A.* 23, 1563). Therefore,  $CoO + CO_2 = CoCO_3 + 7.98$  cal.  $Co + O = CoO + 63.8$  (Dulong) or 57.59 (mixture). For the reaction  $Co + 1\frac{1}{2}O_2 + C = CoCO_3 + Q$ , the values of Q calcd. from these data are 169.43 cal. and 163.13. Detd. calorimetrically,  $Q = 173.31$ .

A. W. CONTIERI

**The decomposition of alkaline carbonates in aqueous solution.** B. L. VANZETTI. *Gazz. chim. ital.* 59, 219–24 (1929).—A preliminary note. A crit. review of the literature, many references to which are cited, shows the unsatisfactory state of knowledge regarding the decompn. of alk. carbonates in water. The expts. of Küster and Grüters (cf. *Ber.* 36, 748 (1903)) indicate that the rate of decompn. of  $\text{Na}_2\text{CO}_3$  in boiling 0.1 *N* soln. is not great, whereas expts. by V. show that under these conditions decompn. is very rapid, about 70% of the  $\text{Na}_2\text{CO}_3$  being decompd. in 120 hrs., even with more concd. solns., a definite law of decompn. being established. These results induced V. to study the influence of this decompn. on the decompn. of carbonates by weak acids, already described (cf. *C. A.* 19, 2461; 20, 1186).  $\text{H}_2$  and air (each free of  $\text{CO}_2$ ) were passed through the system and the  $\text{CO}_2$  was recovered in aq. 50%  $\text{KOH}$  and soda-lime as before. The residual  $\text{CO}_2$  was evolved with  $\text{H}_2\text{SO}_4$  and also detd. In conjunction with the previous expts. of V. (*loc. cit.*), the results show that: (1) dil. (approx. 0.2 *N*)  $\text{Na}_2\text{CO}_3$  and  $\text{K}_2\text{CO}_3$  solns. boiled 5–6 days in a current of inert gas lose 70% or more of the  $\text{CO}_2$ , with formation of  $\text{NaOH}$  and  $\text{KOH}$ , resp., provided that there is no  $\text{CO}_2$  in the atm. over the soln.; (2) this decompn. follows a simple law, the % carbonate decompd. being proportional to the square root of the time; (3) the current of inert gas may be replaced by a current of superheated steam, or the boiling may be carried out in an open receptacle with replenishment of water by water free of  $\text{CO}_2$ ; (4) there is almost no decompn. when operating *in vacuo*, because distn. then occurs at too low a temp. for the  $\text{CO}_2$  to be removed from the sphere of action; (5) by doubling the concn. of carbonate (2%) the actual quantity decompd. is greater but not correspondingly so, *i. e.*, not twice the quantity of  $\text{CO}_2$  is obtained, and (6)  $\text{Li}_2\text{CO}_3$  solns. behave in a similar way, the decompn. following the same law, and not reaching an equil. as supposed by Rosenheim and Reglin. The rate of decompn. is, however, less with  $\text{Li}_2\text{CO}_3$  than with  $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3$  at equal concns., but over 70% was decompd. ultimately. C. C. D.

**Decomposition of barium sulfate.** GERMAINE MARCHAL. *Bull. soc. chim.* 45, 339–43 (1929); cf. *C. A.* 20, 690, 1167.— $\text{BaSO}_4$  (12 g.) was heated with 1.25 g. of  $\text{SiO}_2$  in an alundum boat in a rapid stream of  $\text{N}_2$ . At  $1200^\circ$ , a loss of 6.7% of the wt. of the  $\text{BaSO}_4$  was observed in 1 hr.; at  $1300^\circ$ , 11.9% was lost in 1 hr. and 23.5% in 7 hrs. (theory for total decompn. being 34.2%). At  $1200^\circ$ , a mixt. of 8.12 g. of  $\text{BaSO}_4$  and 2.1 g. of  $\text{SiO}_2$  lost 8.77% in 1 hr. and 17.71% in 5 hrs.; at  $1300^\circ$ , 7.7 g. of  $\text{BaSO}_4$  + 3.4 g. of  $\text{Al}_2\text{O}_3$  lost 12.27% in 1 hr. and 20.65% in 6 hrs.; 7.75 g. of  $\text{BaSO}_4$  + 1.7 g. of  $\text{Al}_2\text{O}_3$  lost 6.29% in 1 hr. and 11.86% in 5 hrs.; 12 g. of  $\text{BaSO}_4$  + 1.54 g. of kaolin lost 9.98% in 1 hr. and 17.27% in 6 hrs.; and 10 g. of  $\text{BaSO}_4$  + 3.17 g. of kaolin lost 17.32% in 1 hr. and 19.18% in 5 hrs.  $\text{BaSO}_4$  heated alone at  $1300^\circ$  under the same conditions lost only 1.36% in 1 hr. and 1.75% in 5 hrs. Addnl. data and curves are given to show the replacement of the more volatile  $\text{H}_2\text{SO}_4$  by  $\text{Al}_2\text{O}_3$ ,  $\text{SiO}_2$ , etc. A. S. CARTER

**Extraction of commercial rare-earth residues with a view to the concentration of Ilinium.** ROBERT W. BALL and J. ALLEN HARRIS. *J. Am. Chem. Soc.* 51, 2107–12 (1929).—Practically complete extn. of double sulfate residues have been obtained for amts up to 300 g. by means of satd.  $\text{NaOH}$  soln. Fusion with  $\text{Na}$  carbonate is equally efficient for larger amts.  $\text{HNO}_3$  and  $\text{H}_2\text{O}_2$  are recommended for the extn. of com. hydrated oxides. FRANK URBAN

**Isotherm at  $20^\circ$  of the three systems:  $\text{La}(\text{NO}_3)_3\text{--Mn}(\text{NO}_3)_2\text{--H}_2\text{O}$ ,  $\text{La}(\text{NO}_3)_3\text{--Mg}(\text{NO}_3)_2\text{--H}_2\text{O}$  and  $\text{Mn}(\text{NO}_3)_2\text{--Mg}(\text{NO}_3)_2\text{--H}_2\text{O}$ .** CLARA DI CAPUA. *Gazz. chim. ital.* 59, 164–9 (1929).—The object of the expts. was to det. whether double salts are formed from aq. solns. satd. with respect to the 2 salts. A temp. below  $25^\circ$  was chosen because at  $25.8^\circ$  there is a transformation of  $\text{Mn}$  salts. There are no references in the literature on the soly. of the 3 salts at  $20^\circ$ . The soly. of  $\text{La}(\text{NO}_3)_3$ ,  $\text{Mn}(\text{NO}_3)_2$  and  $\text{Mg}(\text{NO}_3)_2$  was 60.13, 56.81 and 43.68 g.-%, resp. The system  $\text{La}(\text{NO}_3)_3\text{--Mn}(\text{NO}_3)_2\text{--H}_2\text{O}$  was analyzed by detg.  $\text{La}_2(\text{SO}_4)_3$  +  $\text{MnSO}_4$  and then detg.  $\text{Mn}$  volumetrically by the Knorr method. The system  $\text{La}(\text{NO}_3)_3\text{--Mg}(\text{NO}_3)_2\text{--H}_2\text{O}$  was analyzed by detg.  $\text{La}_2(\text{SO}_4)_3$  +  $\text{MgSO}_4$  and then detg.  $\text{La}_2\text{O}_3$ . In the 3rd system,  $\text{MnSO}_4$  +  $\text{MgSO}_4$  was detd. and then  $\text{Mn}$  by the Knorr method. In all cases the  $\text{H}_2\text{O}$  was detd. by difference. The results, which are given in tables and in triangular graphs, show that no double salts are formed under the conditions used. C. C. DAVIS

**A study of the products obtained by the reducing action of metals upon salts in liquid ammonia solution. I. Introduction. II. The action of sodium upon zinc cyanide.** WAYLAND M. BURGESS and ARTHUR ROSE. *J. Am. Chem. Soc.* 51, 2127–31 (1929).— $\text{Na}$  reacts very readily with  $\text{Zn}$  cyanide in liquid  $\text{NH}_3$  soln., forming a finely divided metallic ppt., extremely reactive with respect to  $\text{H}_2\text{O}$  and air. B. and R. verify the postulation of Kraus and Kurtz (*C. A.* 19, 787) that the formula of the compd. formed is  $\text{NaN}_4$  and give the following equation for the reaction:  $4\text{Zn}(\text{CN})_2 + 9\text{Na} =$

$\text{NaZn}_4 + 8\text{NaCN}$ . A slight excess of Na does not affect the compn. of the ppt. but an excess of  $\text{Zn}(\text{CN})_2$  does change its compn. The oxidation of  $\text{NaZn}_4$  takes place in 2 steps. At first  $\text{O}_2$  is taken up rapidly, with considerable evolution of heat, but no noticeable change in the appearance of the  $\text{NaZn}_4$  takes place. This primary oxidation is followed by a secondary reaction which proceeds at a very slow rate for a long period of time, accompanied by a change in the color of the substance from black through gray to white. Dry air acts in the same way as dry  $\text{O}_2$ . Moist air or moist  $\text{O}_2$  accelerates the oxidation so much that the 2 stages are not apparent. No evidence of the formation of peroxides was obtained in the oxidation expts. Reaction of the compd. with dil. acid liberates 9 equivs. of  $\text{H}_2$  per mol. of  $\text{NaZn}_4$ ; with  $\text{H}_2\text{O}$ , approx. 4.5 equivs. of  $\text{H}_2$  are liberated in 2 months.

A. J. MONACK

**Action of gaseous ammonia on mercuric bromide and mercuric chloride.** MAURICE FRANCOIS. *Compt. rend.* 188, 1500-1 (1929); cf. *Compt. rend.* 129, 296 (1899).—Gaseous  $\text{NH}_3$  conducted slowly over dry  $\text{HgBr}_2$  and  $\text{HgCl}_2$  for a no. of hrs. at room temp. is absorbed in an amt. corresponding to the addn. compds.  $\text{HgBr}_2 \cdot 2\text{NH}_3$  and  $\text{HgCl}_2 \cdot 2\text{NH}_3$ . The reaction between  $\text{NH}_3$  and the solids is slight.

W. C. FERNELIUS

**The reduction of dichromate to basic chromic salts.** G. GRASSER AND T. NAGAHAMA. *Cuir tech.* 18, 2-10 (1929).—See C. A. 23, 1584.

J. G. NIDDERCORN

**New polynuclear coordination compounds of cobalt.** EDMUND G. V. PERCIVAL AND WM. WARDLAW. *J. Chem. Soc.* 1929, 1317-22.—The probable configuration of certain polynuclear amines which contain the  $\text{O}_2$  linkage is discussed. The products formed by the oxidation of such compds. as  $[-(\text{NH}_3)_2\text{-Co-O}_2\text{-Co}(\text{NH}_3)_2] \times 4$  are used as examples. According to Werner, the compd. thus formed has the  $\text{O}_2$  mol. in a more stable configuration than before. It is assigned the formula  $[(\text{NH}_3)_5\text{Co}^{\text{III}}\text{-O}_2\text{-Co}^{\text{IV}}(\text{NH}_3)_5] \times 5$  which postulates the co-existence of ter- and quadrivalent Co. B. and W. have investigated the reactions occurring when dry air is drawn through alc. solns. of  $\text{CoCl}_2$  contg. amines. The reaction with allylamine is confirmed, and satisfactory evidence of the formation of a complex similar to the above was obtained for propylamine and benzylamine. Ethylamine yielded a small quantity of a complex, whereas ethylenediamine, methylamine, diethylamine and piperidine did not. The oxidation of  $\text{CoCl}_2$  in alc. in the presence of amines does not always produce polynuclear complexes, which seem to be formed only in the presence of primary amines contg. the  $\text{CH}_2\text{NH}_2$  group.

L. L. Q

**The formation of hydriodic acid from iodine and water in presence of charcoal.** P. T. DANILCHENKO AND M. I. RAVICH. *J. Russ. Phys.-Chem. Soc.* 61, 123-30 (1929). One g. I, 1 g. charcoal and 200 g. water did not yield any HI when kept for weeks in the dark at room temp.; after a year the concn. of HI reached 0.0102%. No HI was formed in presence of 0.077% KI, 0.056% I and 1 g. charcoal. At 86-92° HI was formed with an appreciable velocity until its concn. reached 0.12%; the equil. is attained at 0.43% HI. On repeated diln. I was completely transformed into HI, although neither HOI nor  $\text{HIO}_2$  was found. HOI is reduced by C as fast as formed and, being a weak electrolyte, has much less influence on the reaction equil. At higher temp. the reaction proceeds faster because of the greater reactivity of HOI and C.  $\text{H}_2\text{O}$  and I vapors were passed over charcoal (ash content 0.23%). At 400-500° little HI is formed, the amt. increasing with the temp. to 98% at 800°. By using more active (porous) charcoal this temp. was lowered to 672°. The yields are higher than could be expected from  $2\text{HI} \rightleftharpoons \text{H}_2 + \text{I}_2$  because of the effect of addnl.  $\text{H}_2$  formed from charcoal and  $\text{H}_2\text{O}$ . The total  $\text{H}_2$  increases with temp., reaching 50% by vol. at 800°, while  $\text{CO}_2$  decreases and the amt of CO remains practically unchanged.

B. SOVENKOFF

**Dichloramine.** ROBERT M. CHAPIN. *J. Am. Chem. Soc.* 51, 2112-7 (1929).—Dichloramine ( $\text{NHCl}_2$ ) is produced by the chlorination of excess  $\text{NH}_4$  ions at  $p_{\text{H}}$  4.4 to 8.5; it is practically the sole ultimate product at  $p_{\text{H}}$  4.5 to 5.0. Monochloramine held at  $p_{\text{H}}$  4.4 to 5.3 undergoes extensive conversion to dichloramine. The reactions leading to dichloramine under the most favorable conditions require at least 1 to 2 hrs. for completion. On the assumption that dichloramine was the sole product present at  $p_{\text{H}}$  slightly above 4.4, the following partition ratios were obtained: Monochloramine in  $\text{CHCl}_3$ , 0.25; dichloramine in  $\text{CHCl}_3$ , 1.88; dichloramine in  $\text{CCl}_4$ , 0.85; dichloramine in ether, 47.3. From the partition ratios of the 2 pure chloramines in  $\text{CHCl}_3$ , the percentage of dichloramine chlorine in total chloramine chlorine may be calcd. from the apparent partition ratio,  $R$ , of a mixt. by the formula,  $44.2 = (4R - 1)/(R + 1)$ . The Cl-N ratio was also used to identify dichloramine.

A. J. MONACK

**Potassium hexathionate.** JAMES R. PARTINGTON AND ALBERT F. TYLER. *J. Chem. Soc.* 1929, 1382-3.—P. and T. confirm in the main details the method used by Weitz and Achterberg (C. A. 22, 1293) for the prepn. of  $\text{K}_2\text{S}_6\text{O}_{12}$ . The  $\text{K}_2\text{S}_6\text{O}_{12}$  was

obtained only when the  $K_2S_2O_8$  used had been prepd. by Foerster and Mommsen's method (C. A. 18, 1254):  $2KSH + 4KHSO_4 = 3K_2S_2O_8 + 3H_2O$ . L. L. QUILL

**The oxidation of tungsten; evidence for the complexity of tungstic oxide,  $WO_3$ .** JOHN STANLEY DUNN. *J. Chem. Soc.* 1929, 1149-50.—The investigation of the oxidation of W by air at temps. between  $700^\circ$  and  $1000^\circ$  showed abnormal variation between  $850^\circ$  and  $900^\circ$ . Conclusion:  $WO_3$  consists of mixt. of  $\alpha$ - $WO_3$  and  $\beta$ - $WO_3$ , whose equil. shifts with temp. since data show that tungstic oxide is in equil. from the beginning of the expt. The color of the oxide is lemon-yellow at ordinary temps. and deep orange at higher temps. M. MCMAHON

**Complex salts. II. The preparation, properties and stability of some bisdicarboxylato copper salts.** HARRY L. RILEY. *J. Chem. Soc.* 1929, 1307-14; cf. C. A. 23, 1076.—It has been suggested that an important factor governing the formation of a coordinate linkage between 2 ions is the distribution of the elec. charges in the donor ions. A comparison of the stabilities of a series of complex ions of the type  $[AX_1]$ ,  $[AX_2]$ ,  $[AX_3]$ , where A is the acceptor ion and  $X_1$ ,  $X_2$ ,  $X_3$  are different donor ions, would give valuable information as to the electron distribution in the series. For that reason, the nature of the compds. obtained when Cu reacts with certain dicarboxylic acids in aq. soln. was studied to det. whether a suitable series of complex ions would be obtained. The Cu forms with these dicarboxylic acids complex salts of the type  $Na_2[Cu(X)_2(H_2O)_2]$  with the Cu probably displaying a coordination no. of 6. The prepn. of the diooxalato-, the dimalonato- and the diphthalato-complex salts has been described. The stabilities of the complexes decrease as follows: oxalato, malonato, phthalato, carbonato and succinato. L. L. QUILL

Equilibrium between the carbonates and bicarbonates of Na and K in aqueous solution at  $25^\circ$  (HILL, SMITH) 2. Configuration of quadrivalent atoms (LOWRY) 2. The mechanism of the abnormal salt formation of pentaphenylchromium hydroxide and a unique H compound of tetraphenylchromium salts (HEIN, *et al.*) 10.

CHÁVEZ, M. JULIO: Contribución al estudio del thiosulfato de sodio. Santiago: Imprenta "San Pablo." 31 pp.

## 7—ANALYTICAL CHEMISTRY

W. T. HALL

**The organization of laboratory work.** A. SULFRIAN. *Metallbörse* 19, 1296-7, 1352-3, 1407-8(1929).—The proper conduct of an analytical lab. for greatest efficiency is discussed in considerable detail. W. C. EBAUGH

**The employment of the quartz spectrograph for the detection of minute quantities of elements.** H. MORITZ. *Metall u. Erz* 26, 247-50(1929).—Cross-sections are brought under the microscope and the particles to be examd. are removed by means of an elec. borer. As much as possible of the powder is brought into soln. and the soln. is concd. by evapn. A spark spectrum is produced with the concd. soln. If the mineral is insol., it is of advantage to produce an arc spectrum. In this case the powder is placed into the hollow part of an excavated + carbon of a micro arc lamp. The elements H, O, N, F, Cl, Br, I, S and Se present difficulties when examd. by the ultra-violet spectrum, because they do not emit lines under normal atm. pressure. Lines will appear, however, when the material under examn. is converted into a salt, the salt fused on top of the electrodes and a spark spectrum produced. Lines are also obtained when a spark spectrum is produced between a Pt spoon (cathode), which contains the material fused with the flux and a Pt wire (anode). Li and K are difficult to recognize because even in a concn. of over 1% a weak line could be detected only in a few cases. Apart from the rare gases, which were not examd., all other elements not mentioned so far emit typical lines, thus making it possible to obtain at once a complete qual. analysis. M. worked out a method of quant. analysis with the quartz spectrograph which is based on the fact that with decreasing concn. of the element, the no. and the intensity of the lines decrease, with exception of the "persistent lines." A series of standards was prepd. which contained decreasing amts. of the element under consideration. By comparing the standards with the sample to be tested the concn. of the element in the unknown sample could be estd. The method is useful at concns. between 0.001 and 1%. In a few cases (Pb, Zn, Cu) the content could be detd. even between 0.001 and 0.0001%. The standard samples should resemble the test samples regarding their state of aggregation. G. SCHWOCH

**The use of the alloy "weta" in analysis.** B. ZIMMERMANN. *Listy Cukrovar.* 47, 435-6(1929).—"Weta" is a new alloy of dispersed carborundum and quartz in Fe, Co and Ni and is superior in quality to porcelain. It is not porous, quite light, and withstands rapid changes in temp. Porcelain crucibles weighing 17 g. heated in a muffle furnace at 700° showed a loss of 0.0003 g. after the 2nd heating, and 0.0001 g. after the 3rd. Weta crucibles weighing 15 g. gained 0.0010 and 0.0032 g., resp., during the same heating indicating an oxidation process. The resistance to the action of HCl is inadequate: soaking the crucibles in cold dil. HCl for 24 hr. showed a yellow color and gave an Fe test. The increase in weight following ignition ranged from 44 to 42.7 mg. Z. recommends the alloy for preps. but not for analytical work. FRANK MARESH

**Notes on the analytical utilization of complex chemical and induced reactions.** F. FEIGL AND P. KRUMHOLZ. *Ber.* 62B, 1138-42(1929).— $\text{H}_2\text{SiO}_3$ , like  $\text{H}_3\text{PO}_4$ , unites with  $\text{H}_2\text{MoO}_4$  to form a complex acid which is capable of oxidizing benzidine to a blue compd. The  $\text{H}_2\text{SiO}_3$  complex differs from the  $\text{H}_3\text{PO}_4$  complex with  $\text{H}_2\text{MoO}_4$  by being quite sol. in water. By adding to 1 cc. of the dil. HCl or  $\text{HNO}_3$  soln. to be tested (the acidity must not be greater than 0.5 N) 2 drops of acid molybdate reagent and heating till the mixt. begins to boil, the silico complex is formed and after cooling and adding 1-2 drops of 0.25% soln. of benzidine in 10% AcOH and an equal vol. of satd. AcOH, a blue ppt., or coloration, is formed which is an extremely sensitive test for Si. The same reaction can be utilized as a test for F. A fluoride heated with  $\text{SiO}_2$  and concd.  $\text{H}_2\text{SO}_4$  gives volatile  $\text{SiF}_4$ , which on coming in contact with a drop of water gives  $\text{H}_2\text{SiO}_3$  and this will respond to the above test. As an example of an induced reaction, the behavior of Pb toward alk.  $\text{Na}_2\text{SnO}_2$  soln. is interesting. When an appreciable quantity of Bi is present, it is easily reduced to finely divided black metal by alk.  $\text{Na}_2\text{SnO}_2$  soln. but Pb salts under similar conditions are reduced only very slowly even upon heating. If, however, a very little Bi soln. is added to the soln. of a Pb salt, the reduction to Pb takes place very quickly. In fact the effect of Bi is so marked that it requires a mere trace of Bi to bring about this reduction of the Pb and the test may be used to detect a very minute quantity of Bi. W. T. H.

**Recommended specifications for analytical reagent chemicals.** W. D. COLLINS, H. V. FARR, JOSEPH ROSIN, G. C. SPENCER AND EDWARD WICHERS. *Ind. Eng. Chem., Anal. Ed.* 1, 171-4(1929).—Specifications are given for Br, cupric ammonium chloride, CuO powd. and granular,  $(\text{C}_2\text{H}_5)_2\text{O}$ ,  $(\text{C}_2\text{H}_5)_2\text{O}$  abs.,  $\text{K}_2\text{CrO}_4$ , K Na tartrate,  $\text{Ag}_2\text{SO}_4$ , zinc low in As, and zinc low in Pb and Fe. E. H.

**Preparation of alloxantin, reagent for ferric iron.** GEORGES DENIGÈS. *Bull. soc. pharm. Bordeaux* 66, 8-12(1928).—Two methods of prepg. alloxantin, a reagent for  $\text{Fe}^{+++}$ , are given: (1) Place in a  $\frac{1}{2}$  l. conical flask 10 g. of pure uric acid, add 10 cc. concd.  $\text{HNO}_3$ , heat and shake. After standing 1-3 min. a vigorous reaction occurs with liberation of  $\text{NO}_2$ . When effervescence ceases add 10 cc. of distd. water and boil gently until the mixt. becomes clear. Pour into the flask 200 cc. distd. water, 1 cc. of pure HCl and introduce a strong current of  $\text{H}_2\text{S}$  for 30 min. The liquid becomes turbid with formation of yellow-white masses. Boil 10 min., filter, boil again, filter and collect filtrate in a porcelain dish. Allow to cool and let stand 2 days. Wash the crystals that have settled out with cold water several times. Drain and dry on filter paper. (2) Place in a round-bottomed flask 15 g. uric acid, 30 g. concd. HCl and 40 cc. distd. water. Heat the mixt. to 30°, add in small portions 4 g. of  $\text{KClO}_3$  during 45 min., filter, dil. with 30 cc. water and sat. the liquid with  $\text{H}_2\text{S}$ . Crystals of alloxantin and S are formed. Filter, wash the ppt. with cold water and dissolve the alloxantin in boiling water. Filter the insol. S, cool the filtrate; alloxantin separates out in the form of prisms. A. G. DuMEZ

**A new qualitative reagent for sodium.** EARLE R. CALEY. *J. Am. Chem. Soc.* 51, 1965-9(1929).—By mixing a 4% soln. of  $\text{U}(\text{OAc})_3$  crystals in 3% AcOH with a 20% soln. of  $\text{Co}(\text{OAc})_2$  crystals in 3% AcOH, a reagent is obtained which, when 20 cc. are shaken with 1 cc. of the soln. to be tested, gives a yellow ppt. of  $[\text{NaCo}(\text{UO}_2)_3]$  acetate even in the presence of over 0.1 g. of K. Attempts to work out a quant. method were unsuccessful. W. T. H.

**Salt error of indicators due to standard alkaline buffers themselves.** II. J. W. MCBAIN, M. E. LAING AND O. E. CLARK. *J. Gen. Physiol.* 12, 695-710(1929); cf. *C. A.* 21, 871.—Previous results on the comparison of colors given by indicators in alk. buffer solns. and pure aq. NaOH soln. have been confirmed. The NaOH soln. used gave theoretical values for concn. of OH-ion. "The slight but distinct neutralizing effect of dil. sols. of alkali has been measured electrometrically and the allowances to be made are recorded graphically. It is found that whereas alizarin yellow G, tropeolin (1) and thymol violet may be used without appreciable error (in accordance with our previous

communication) the grave discrepancies remain for phenolphthalein, *o*-cresolphthalein, thymol blue and phenol red which must be ascribed to salt error in the alk. buffer itself."

C. H. RICHARDSON

**Potentiometric determinations with ferricyanide in alkaline solution. I. Vanadate and hydrosulfite.** CARLOS DEL FRESNO AND LUIS VALDÉS. *Anales soc. españ. fis. quim.* 27, 368–89 (1929).—Ekker, Palmer, Bollenbach and Luchman proposed methods of detn. of various substances by  $K_3Fe(CN)_6$  in alk. soln., using up to a 5 times excess of the latter, titrating the  $K_4Fe(CN)_6$  by  $KMnO_4$  after removal of oxidation products. Since  $K_3Fe(CN)_6$  can be produced in a very pure state, has a large equiv. wt. and its soln. remains almost unchanged for years at ordinary temp. and in the dark, it was applied to direct potentiometric titration in general. Heretofore only  $Ce^{IV}$  and  $Cr^{III}$  have been detd. in this way.  $V_2O_5$  was reduced by  $SO_2$  in  $H_2SO_4$  soln. to  $V_2O_4$ , then made alk. with exclusion of air.  $Na_2S_2O_4$  was used direct. Titrations were made in a current of N. Potentials formed rapidly and the potential differences are rather high. The effect of temp. and alky. upon titration curves was studied, using NaOH at various concns.,  $Na_2CO_3$ ,  $NH_4OH$  and buffered solns. with Na borate and  $H_3BO_3$ . With increase in OH the curves of potential difference are displaced toward the negative potential and the differences increase simultaneously. The quant. agreement is good. With V the inverse reaction was studied. The alk.  $K_3Fe(CN)_6$  soln. was titrated with a slightly acid  $VOSO_4$  soln. and a large difference found, with good quant. agreement.

E. M. SYMMES

**Smith's method for the determination of arsenic.** YU D. GNESIN. *Zhur.* 1928, 442 4.—The method of Smith (as described by J. Gadamer, *Lehrbuch der chem. Toxicologie* 167, cf. C. A. 18, 2668) can be used for the detn. of As in quantities as low as 0.07 mg by G.'s improvement of Smith's app., which consists in providing the latter with a separatory funnel allowing the dropwise addn. of the liquid to be tested. E. B.

**Recent developments in the analysis of carbon in iron and iron alloys.** NICHOLAS A. ZIEGLER. *Trans. Am. Electrochem. Soc.* 56 (preprint) 8 pp (1929).—Modifications and improvements in the "Yensen" method for accurate detn. of C in Fe and Fe alloys are described. The Yensen method consists in heating the sample in a vacuum to  $1050^\circ$  and heating in pure  $O_2$ . The gaseous products of oxidation are slowly passed through a trap immersed in liquid air. All  $CO_2$  freezes out and remains in the trap. If this  $CO_2$  is expanded into a known vol., the pressure is a measure of the amt. of C originally present in the sample. The error in the method is of the order of  $\pm 0.01$  mg., corresponding to  $\pm 0.0005\%$  for a 2-g. sample. With extra precautions the error can be reduced to  $\pm 0.0001\%$ .

C. G. F.

**Cobalt determination in driers, japans, alloys, etc.** OSCAR HEIM. *J. Oil and Colour Chem. Assoc.* 12, 175–6 (1929).—Vogel's qual. test has been made quant. The metals are obtained in a weak HCl soln.  $ZnO$  is added at  $50^\circ$  until only a visible trace remains undissolved. The ppt. is filtered and washed with warm water. The filtrate, concd. to 20 cc., is transferred to a separatory funnel. The total vol. in the funnel must not be more than 50 cc., in which 30 g. of  $NH_4CNS$  is then dissolved. The soln. is extd. with ether-amyl alc. (9:1). The ether soln. is now extd. with 20 cc.  $H_2SO_4$  and washed several times with water. The Co now can be detd. by electrolysis, as  $CoO$ , or as the 3,5-dimethylpyrazole compd.

G. G. SWARD

**Determination of copper in molybdenum ore.** M. G. RAEDER. *Tids. Kemi Bergvesen* 8, 91–3 (1928).—Place 1 g. of concentrates in a 250-cc. beaker, and add 25 cc. of aqua regia and 6–7 cc.  $H_2SO_4$ . Cover with a watch glass and heat gently till the greater part of the ore ( $MoS_2$ ) is dissolved. Evap. to fumes of  $SO_3$ , dissolve in 100 cc. of boiling water and filter into a 500-cc. beaker. Dil. to 2–300 cc., boil, and add  $Na_2CO_3$  until a pale color due to S is obtained. Then boil 3–5 min., filter hot and wash with hot  $SO_2$ -water. Incinerate and det. Cu by the method of Low.

A. D.

**The determination of ferrous iron in silicate rocks. II. Electrometric.** BYRON A. SOULE. *J. Am. Chem. Soc.* 51, 2117–20 (1929).—It has already been found (C. A. 22, 2897) that silicate powder can be decompd. by HCl and HF in an atm. of  $CO_2$  and the  $Fe^{++}$  detd. in the resulting soln. With  $KMnO_4$  however, a correction had to be applied possibly because of As in the glass. By using  $Ce(SO_4)_2$  in place of  $KMnO_4$  and detg. the end point electrometrically, correct values were obtained without the need of applying a correction factor. The  $Ce(SO_4)_2$ , being a weaker oxidizing agent than  $KMnO_4$ , is not affected by any As present.

W. T. H.

**Direct volumetric determination of potassium and sodium, applicable to other alkalies and alkaline earth metals.** F. DÍAZ DE RADA. *Anales soc. españ. fis. quim.* 27, 390–9 (1929).—The Na ion can be detd. directly by volumetric methods with  $Li_2Fe(CN)_6$  in neutral or AcOH soln. if 80–82% alc. is added. The  $Na_4Fe(CN)_6$  formed is practically

insol. under these conditions. The end of the reaction is detd. by the touch method on a  $\text{Co}(\text{NO}_3)_2$  paper, giving a very sensitive green-blue color.  $\text{NH}_4$ , K, Rb and Cs also ppt. completely at various concns. of alc., the reaction being  $\text{Li}_2\text{Fe}(\text{CN})_6 + \text{M}_2\text{SO}_4 = \text{Li}_2\text{M}_2\text{Fe}(\text{CN})_6 + \text{Li}_2\text{SO}_4$ . Mg, Ba, Sr and Ca are also pptd. as simple ferrocyanides. Another, more practical method is to titrate K in the precipitant by  $\text{Li}_2\text{Fe}(\text{CN})_6$  in the presence of a Ca salt such as  $\text{CaK}_2\text{Fe}(\text{CN})_6$ , in 50% alc. soln., in which it is practically insol. Lack of Ca can give serious errors, while an excess does not harm the sensitivity of the indicator. In dil. soln. this method will det. K in the presence of 4 or 5 times as much Na. Detg. first K + Na, then K alone by the latter method, is recommended.

E. M. SYMMES

**A gravimetric and colorimetric method for the direct determination of sodium.** EARLE R. CALLEY AND C. W. FOULK. *J. Am. Chem. Soc.* 51, 1664-74(1929).—By mixing an 8.5% soln. of  $\text{UO}_2(\text{OAc})_2$  in 6%  $\text{AcOH}$  with a 50% soln. of  $\text{Mg}(\text{OAc})_2$  in 6%  $\text{AcOH}$ , and filtering after the soln. has stood for some time at  $20^\circ$ , a reagent is obtained which can be used for the direct gravimetric or colorimetric detn. of Na. Close attention must be paid, in using this reagent, to temp., stirring and concn. At  $20^\circ$  a ppt of  $\text{Na}(\text{OAc})\cdot\text{Mg}(\text{OAc})_2\cdot 3\text{UO}_2(\text{OAc})_2\cdot 6.5\text{H}_2\text{O}$  is obtained, which can be dried at  $105^\circ$  for 30 min. without decompn. and contains 1.53% Na. 1-5 cc. of soln. contg. 1-50 mg. of Na should be mixed with 100-500 cc. of the reagent at  $20^\circ$  and the mixed soln. stirred vigorously for 30-45 min. Filter and wash with alc. satd with reagent. The presence of  $\text{NH}_4$  or small quantities of K does no harm but Li must be absent. The ppt. dissolves in hot water, giving a yellow soln. which, when cold, can be compared with the color produced similarly by known amts. of Na. Not more than 5 mg. of Na should be present for the colorimetric detn.

W. T. H.

**The determination of the tin coating on tin plate.** FRITZ PETER. *Chem.-Ztg.* 53, 438-9(1929).—Weigh a measured piece of tin plate ( $100 \times 200$  mm.), roll it so that its surfaces do not touch, and immerse in  $\text{HCl}$  (d. 1.08) at almost boiling temp. in a high 350-cc. beaker until the coating has dissolved. Some Fe dissolves also, as shown by the more rapid evolution of H. Withdraw the sample, wash with  $\text{H}_2\text{O}$  and abs.  $\text{EtOH}$ , and burn off the latter while shaking. Cool in a desiccator and weigh. Make up the soln. to 500 cc., take a 100 cc. sample, oxidize with  $\text{KClO}_3$ , boil, and det. Fe by Zimmerman-Reinhardt method. To the Fe found add 0.4% (the normal amt. of impurities in the steel); deduct from the loss in wt. of the original sample the total steel calcd. as above, and call the remainder Sn.

W. C. FBAUGH

**The separation of thorium from uranium by means of ether.** PAUL MISCIATTELLI. *Phil. Mag.* [7], 7, 670-4(1929).—See C. A. 23, 1554.

L. H. REYERSON

**Volumetric determination of vanadium, iron, and uranium with titanium salts.** V. G. KHLOPIN AND L. E. KAUFMAN. *Zhur. Prikladnoi Khim.* 2, 91-108(1928).—Salts of tervalent Ti reduce  $\text{V}^{\text{V}}$ ,  $\text{Fe}^{\text{III}}$  and  $\text{U}^{\text{VI}}$  in acid soln. in the following order  $\text{V}^{\text{V}}$  to  $\text{V}^{\text{IV}}$ ,  $\text{Fe}^{\text{III}}$  to  $\text{Fe}^{\text{II}}$ ,  $\text{U}^{\text{VI}}$  to  $\text{U}^{\text{IV}}$  and  $\text{V}^{\text{IV}}$  to  $\text{V}^{\text{III}}$ .  $\text{V}^{\text{V}}$  is titrated with 0.05-0.1 N  $\text{Ti}^{\text{III}}$ ,  $\text{K}_3\text{FeC}_6\text{N}_6$  and  $\text{Fe}^{\text{III}}$  being used as indicators,  $\text{Fe}^{\text{III}}$  is detd. by the method of Knecht and Hibbert (*Ber.* 36, 1551), KCNS being used as indicator, and  $\text{U}^{\text{VI}}$  is titrated with Neublau G(C) as indicator. All titrations are made in an atm. of  $\text{CO}_2$ .

V. KALICHEVSKY

**The potentiometric determination of bromine, octavalent and quadrivalent osmium in hydrobromic acid solutions.** WM. R. CROWELL AND H. DARWIN KIRSCHMAN. *J. Am. Chem. Soc.* 51, 1695-1702(1929).—If a soln. contg. free Br, octavalent Os and HBr is titrated with  $\text{TiCl}_3$  in  $\text{N}_2$ , 3 inflection points are obtained potentiometrically. The first corresponds to the reduction of Br to  $\text{Br}^-$ , the second to the reduction of octavalent to quadrivalent Os and the third to the reduction of Os to the tervalent condition. The first 2 are suitable for the detn. of  $\text{Br}_2$  and Os when present together in HBr soln. but the third inflection is not sufficiently sharp.

W. T. H.

**Determination of chlorine and phosgene in a mixture of the two.** S. PLETNEV. *Lab. Praktika* 4, No. 2(1928); *Farm. Zhur.* 1928, 715.—In a specially designed app the mixt. of Cl and  $\text{COCl}_2$  is collected in one of two tubes. One of them contains a definite quantity of N NaOH which transforms  $\text{COCl}_2$  into the chloride and Cl into NaOCl. By subsequently adding slowly a soln. of  $\text{As}_2\text{O}_3$  and  $\text{Na}_2\text{CO}_3$ , the NaOCl is transformed into chloride too. The total chloride is then detd. by Volhard's method. In a second expt. the gas is brought into contact in the KI soln. and the residual  $\text{I}_2$  (liberated by free  $\text{Cl}_2$ ) titrated with  $\text{Na}_2\text{S}_2\text{O}_3$ . The quantity of  $\text{COCl}_2$  is obtained by subtracting the quantity of free Cl from the total Cl previously obtained.

Y. POROSOWSKY

**Analysis of insecticides containing fluorine compounds.** LESLIE HART. *Ind. Eng. Chem., Anal. Ed.* 1, 133-5(1929).—For preps. contg. alkali fluosilicates and boric

acid, first det. the total acidity by titrating 50 cc. of hot soln. (contg. about 0.4 g.  $\text{B}_2\text{O}_3$ ) with 0.2 N NaOH using phenolphthalein as indicator, adding 30 cc. of glycerol as soon as the first permanent pink is obtained and completing the titration at about 5°. Four mols. of NaOH will be required for each mol. of  $\text{SiF}_6^{--}$  and 1 mol. for each mol. of  $\text{H}_3\text{BO}_3$ . With another sample, remove  $\text{SiF}_6^{--}$  by pptn. with KCl and alc. Then, without filtering, add glycerol and titrate the  $\text{H}_3\text{BO}_3$  at 5°. Deduct the value now obtained from the total acidity to get the  $\text{SiF}_6^{--}$  and run a blank on all the reagents. For preps. contg. water-sol. fluorides and sol. arsenicals, oxidize the As by  $\text{H}_2\text{O}_2$  in  $\text{Na}_2\text{CO}_3$  soln. and ppt.  $\text{Ag}_3\text{AsO}_4$  in carefully buffered soln. Use the ppt. for the As detn., choosing a distn. method. Take an aliquot part of the filtrate, ppt. excess Ag with NaCl, filter and use another aliquot for the F detn., Gooch's gravimetric method being recommended. For the analysis of a mixt. of NaF, NaHF<sub>2</sub> and  $\text{Na}_2\text{SiF}_6$ , det. the total acidity with NaOH and assume 1 NaOH used for NaHF<sub>2</sub> and 4 NaOH for  $\text{Na}_2\text{SiF}_6$ . Then det. the total F by the gravimetric method of Gooch. For the NaHF<sub>2</sub> detn., add 1 g. of KCl to the soln. of 0.5 g. powder in 25 cc. of water and 25 cc. of alc. Cool to near 0° and titrate with NaOH free from carbonate. The analysis of various products showed that a sample of commercial  $\text{Na}_2\text{SiF}_6$  contained a little NaF and NaHF<sub>2</sub>, commercial NaF contained over 4%  $\text{Na}_2\text{SiF}_6$  and some NaHF<sub>2</sub> while commercial NaHF<sub>2</sub> contained about 29% NaHF<sub>2</sub>, 10%  $\text{Na}_2\text{SiF}_6$  and 60% NaF. W. T. H.

**Improvements in the Denigès colorimetric method for phosphorus and arsenic.** EMIL TRUOG AND A. H. MEYER. *Ind. Eng. Chem., Anal. Ed.* 1, 136-9 (1929).—Denigès has shown that a very sensitive test for  $\text{H}_3\text{PO}_4$  and  $\text{H}_3\text{AsO}_4$  is obtained by adding  $(\text{NH}_4)_2\text{MoO}_4$  and  $\text{SnCl}_2$ , a blue color being produced. The method of applying the test is now improved by prepg. a soln. of  $\text{SnCl}_2$  from crystals of this salt and keeping the soln. under white mineral oil. This soln. keeps very much better than the soln. obtained by dissolving Sn in HCl. Better results are also obtained by doubling the quantity of molybdate reagent and increasing the acidity somewhat. Directions are given for applying the test in the analysis of water, soils, minerals, fertilizers, etc. W. T. H.

**Oxygen determination (in gas) by the Lubberger-Wunsch method.** ANON. *Gay u. Wasserfach* 72, 525-6 (1929).—A 3-5-l. cork-stoppered bottle, the vol. of which is known, and which is provided with a side tube closed by a stopcock and with a dropping funnel, is filled with gas. Ten cc. of  $\text{MnCl}_2$  soln. contg. 10 g. of  $\text{MnCl}_2$  in 100 cc. of slightly acidified water, is added per l. of gas. The dropping funnel is then carefully washed out with water and 30 cc. of a sol. contg. 10 g. NaOH, 35 g. Rochelle salt and 85 g. KI in 300 cc. water added for each l. of gas. After equalizing the pressure on the bottle it is shaken mechanically 1.5 hrs. Concd. HCl, 10 cc. per liter of gas, is then added and the soln. shaken. It is then washed into a beaker and titrated with 0.1 N  $\text{Na}_2\text{S}_2\text{O}_3$ , 1 cc. of which equals 0.560 cc. O at 0° and 760 mm. A sample computation is given. If all precautions are followed concordant results are obtained.

R. W. RYAN

**A contribution to the quantitative spectral analysis of solutions.** FR. GROMANN. *Z. anorg. allgem. Chem.* 180, 257-74 (1929).—A new spark gap with metal electrodes and an improved exciting circuit are described and applied to the analysis of very dil. solns. of Hg salts, particularly the sulfide. G. found that adding CuS to the soln. increased the sensitivity of the app. A discussion is given of the technic, sensitivity and accuracy of this method of analysis.

J. B. AUSTIN

**A drop test for the estimation of the stability of emulsions.** G. GOETTSCHE. *Chem. Weekblad* 26, 336-8 (1929).—To det. quickly the stability of fungicidal liquids a method is described which depends upon the shapes taken when a little of the liquid is dropped into water. An app. is described by which it is possible to obtain reproducible results.

F. DE LEEUW

**Lime analysis.** C. A. DOLGOV. *Nauch. Zapiski Sakhornoi Prom.* 8, 22-38 (1929).—For detn. of total CaO, the conventional method is satisfactory. Free CaO can be detd. by using the glycerol-boric acid titration or the following method can be used: Weigh out 5 g. of lime into a 500-cc. flask. Add 400-450 cc. of boiling  $\text{H}_2\text{O}$  and 50 g. of pure granulated sugar. Shake and make up to the mark with boiled cold  $\text{H}_2\text{O}$ . Discard first 150-200 cc. of filtrate and titrate the rest of the filtrate with 0.5 N HCl, phenolphthalein being used as indicator.

V. E. BAIKOW

**Determination of iron oxides in acid furnace slags.** GEORGE T. DOUGHERTY. *Ind. Eng. Chem., Anal. Ed.* 1, 163 (1929).—Routine methods are described for obtaining the  $\text{FeO}$  and  $\text{Fe}_2\text{O}_3$  in steel furnace slag, the samples being decomposed by  $\text{H}_2\text{SO}_4$  and HF in Pb test tubes on a sand bath.

DOWNES SCHAAP

**The analysis of "Glanzmetall."** LEO SCHWEITZER. *Chem.-Ztg.* 53, 457-9 (1929).—"Glanzmetall" is the name given to some bright alloys which are often made by work-

ing up metal wastes. They differ from the usual Cu alloys by contg. more Sb and from common Sn alloys by contg. more Cu. *Detn. of Cu and Pb*.—Digest 0.5 g. of alloy in a porcelain dish with 15 cc. of Br<sub>2</sub> with 9 vols. of 40% HBr. Evap. to dryness, add 10 cc. more of Br-HBr, evap. again and allow the residue to stand at least 15 min. in a warm place and then digest with 40 cc. of 7.5 N HNO<sub>3</sub> and boil till all Br is expelled. Then rinse into a beaker and det. Cu and Pb simultaneously by electrolysis. *Detn. of Sn*. If the Cu content is less than about 12% and As less than 1% choose (I) from the following procedures, and (III) if more As is present. If more Cu is present, use (II) if less than 10% Sb is present and (III) if more than 10% Sb. (I) Treat 0.5 g. of alloy with 50 cc. of Br-HCl, remove excess Br and reduce with *ferrum reductum*, filter and titrate with I<sub>2</sub>. (II) Treat 0.5 g. alloy with a mixt. of 30 cc. HCl and 5 cc. HNO<sub>3</sub>, warming gently. Treat the soln. with excess NH<sub>4</sub>OH and 5–10 g. of (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>. After 3 hrs. in a fairly warm place, filter, wash with hot water and treat the ppt. as in Method I. (III) Digest 0.5 g. of metal with 15 cc. of concd. HNO<sub>3</sub> and dil. with 100 cc. of water. After the ppt. has settled, filter with paper pulp and fuse the ppt. in an Fe crucible with Na<sub>2</sub>O<sub>2</sub>. Ext. the melt with water and stir with HCl until dissolved. Continue as in (I). *Detn. of Sb*. Of the following 3 methods, use (I) when less than 15% of Cu is present and less than 0.5% Fe and 0.5% As; if more Fe is present and the As content is low, use (II) and when more than 0.5% As is present use (III). When more than 15% of Cu is present, use (IV) with less than about 0.8% of Fe present otherwise use (III). (I) Det. the Sb by Low's method of dissolving in concd. H<sub>2</sub>SO<sub>4</sub> and titrating with KMnO<sub>4</sub> in the presence of HCl. (II) Dissolve 1 g. of metal in 30 cc. HCl and 5 cc. HNO<sub>3</sub>, dil. with water and nearly neutralize with NH<sub>4</sub>. Boil and introduce H<sub>2</sub>S, preferably adding 5 g. of oxalic acid to keep Sn in soln. Filter and wash back the ppt. into the original flask, using a little Na<sub>2</sub>S soln. to remove the last traces of ppt. from the filter. Add 25 cc. of concd. H<sub>2</sub>SO<sub>4</sub> and a few crystals of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Heat to fumes of H<sub>2</sub>SO<sub>4</sub> and continue as in (I). (III) Treat the metal as in the third method given for Sn, eventually fusing with Na<sub>2</sub>O<sub>2</sub>. To the slightly acid soln. obtained after fusing, add H<sub>2</sub>S, filter off the ppt., and treat as in method (II). For the detn. of Ni, Fe and Zn, use the filtrate from the H<sub>2</sub>S pptn. and analyze in the usual way. For the As detn., decompose 2–5 g. of alloy with 5 g. KBr, 50 cc. of satd. FeCl<sub>3</sub> soln., 165 cc. of concd. HCl and 35 cc. of water, and catch the distillate in dil. HCl, eventually titrating with I<sub>2</sub> after neutralizing with NaHCO<sub>3</sub>. If so much S is present that As<sub>2</sub>S<sub>3</sub> ppts. during the distn., weigh the As in this form. For the S detn. boil 2 hrs. with 100 cc. of concd. HCl in a stream of CO<sub>2</sub> and catch the distillate in AcOH soln. of Cd and Zn acetates. Finally treat with CuSO<sub>4</sub> soln., filter off the CuS, ignite and weigh as CuO.

W. T. H.

**Note on the determination of silica in steel.** ROLAND WASMUHT. *Z. anorg. Chem.* 42, 526–7(1929).—P. DICKENS (*Chem. Fabrik* 2, 51(1929)) obtained too high results by the Br-KBr method of Oberhoffer. This difficulty resulted, probably, from the formation of SiBr<sub>4</sub> from FeSi and subsequent hydrolysis of the SiBr<sub>4</sub>. It is easily possible to remove this secondary H<sub>2</sub>SiO<sub>3</sub> by washing the ppt. with dil. Na<sub>2</sub>CO<sub>3</sub>, which does not dissolve the strongly heated SiO<sub>2</sub> in the original metal. A simple shaking device is shown and detailed directions given by which the SiO<sub>2</sub> of Fe and steel can be detd. satisfactorily by the Br-KBr method.

W. T. H.

**Bimetallic electrodes for titrations involving a change of hydrogen-ion concentration.** RAYMOND M. FUOSS. *Ind. Eng. Chem., Anal. Ed.* 1, 125–8(1929).—The following electrode pairs were used for the titration of various acid and basic solns; Sb-Pb, Sb-HgCu, B-Ag, and Cu-CuO. For general use, the Sb vs. amalgamated Cu electrode is most satisfactory. Curves are shown for the titration of NaOH with HCl, HCl with NaOH, Na<sub>2</sub>CO<sub>3</sub> with HCl and AcOH with NaOH and CuSO<sub>4</sub> with NaOH.

W. T. H.

**The solubility of gold in mercury.** ARTHUR A. SUNIER AND BRUCE E. GRAMKEE. *J. Am. Chem. Soc.* 51, 1703–8(1929).—The empirical equation,  $\log N = -1167/T + 0.966$ , expresses the exptl. results up to 160° but not at higher temps. The results agree well with those obtained by Kasanzeff in 1878 but are lower than those obtained subsequently by Parravano and by Britton and McBain. They do not agree at all with the results of Braley and Schneider. For the analysis, the samples were heated in H<sub>2</sub> at about 200° until no more Hg could be seen and then the temp. was raised to about 550° which was necessary to remove the last traces of Hg. Expts. with pure Au and pure Hg showed that the wt. of Au obtained in this way agreed with the wt. taken.

W. T. H.

**Sodium maleate—a buffer for the p<sub>H</sub> region of 5.2–6.8.** J. W. TEMPLE. *J. Am. Chem. Soc.* 51, 1754–5(1929).—The advantage of NaHC<sub>4</sub>H<sub>3</sub>O<sub>4</sub>·3H<sub>2</sub>O + NaOH

for prepg. suitable buffer solns. lies in the fact that the max. buffering power is in the region where phthalate and phosphate buffers have the least efficiency. Directions are given for making the salt and for prepg. 9 solns. of definite H-ion concn. from pH 5.3-6.8. W. T. H.

**Estimation of alcohol in dilute water solutions by the permanganate method.** B. Y. ROZMAN. *Zhur. Prikladnoi Khim.* 2, 191-8(1929).—Mix 50 cc. of the sample and 50 cc. of 0.1 N  $\text{KMnO}_4$  in a 500 cc. Erlenmeyer flask. Add 20 cc. of concd.  $\text{H}_2\text{SO}_4$  in about 4-6 sec. without mixing. After 1 min. add 100 cc. of cold water, mix and add 50 cc. of 0.1 N oxalic acid soln. ( $\text{Na}_2\text{C}_2\text{O}_4$  soln. is permissible.) Heat almost to boiling and titrate the excess of oxalic acid with 0.1 N  $\text{KMnO}_4$ . The method is satisfactory for solns. contg. 0.1-0.05% of EtOH. More concd. solns. should be dild. to this strength. The presence of  $\text{Et}_2\text{O}$  affects the accuracy of the results. V. K.

**Detection of isopropyl alcohol in alcoholic preparations.** C. STAINER AND A. LAUWAERT. *J. pharm. Belg.* 10, 167-9(1928).—A comparative study of some reactions employed in the analysis of alcs. and acetone. With respect to isopropyl alc. it was found:—That Et and Am alc. give acetic ethers with distinct odors while isopropyl alc. does not; that the iodoform test is given by acetone, Et and isopropyl alcs.; that isopropyl alc. does not affect the detection of acetone by Legal's test, of methanol by the U. S. P. test (Trillat and Denigés), or of ethanol in methanol (Denigés test). Denigés reagent ( $\text{HgO}$  50 g., concd.  $\text{H}_2\text{SO}_4$  200 cc., distd. water 1000 cc.). The reagent when brought to a boil is not affected by the addn. of a few drops of the following: Me, Et and Am alc., or ether. With acetone and formaldehyde, it gives a white ppt. after shaking; with pure isopropyl alc. or mixts. of it and any of the above, the reagent gives a yellow ppt. (not white as stated by D.). The test cannot be employed in the presence of hydrocarbons, as petrolatum, which also give a yellow ppt. Directions are given for this test in some special medicaments. A. G. DuMEZ

**Estimation of formaldehyde via the D. A. B. 6.** WALTER MEYER. *Pharm. Ztg.* 74, 771-3(1929).—A crit. review of the official Ger. Pharm. (I method) method with certain other suggested methods (sulfite,  $\text{NH}_3$ , and  $\text{H}_2\text{O}_2$  methods). Working with the purest reagents, the D. A. B. 6 method proved entirely satisfactory, though rather expensive. From the standpoint of cheapness and simplicity, however, both the sulfite and the  $\text{NH}_3$  methods are preferred. The  $\text{H}_2\text{O}_2$  procedure is least satisfactory. W. O. E.

**Rapid method for determination of phenols.** J. A. SHAW. *Ind. Eng. Chem., Anal. Ed.* 1, 118-21(1929).—With a special app., easily made in any lab., 10 cc. of sample is steam distd. to give 25 cc. distillate. This is divided into portions, diluted until the concn. lies between 30 and 35 p. p. m., brought to 20°, Br- $\text{H}_2\text{O}$  added, shaken and the turbidity instantly compared with that in 30 and 35 p. p. m. standards. Alcs., amines, aldehydes, org. bases, oils and inorg. salts interfere. ALDEN H. EMERY

**Detection of  $\alpha$ - and  $\beta$ -naphthol by ultra-violet rays.** T. YOKOI AND M. ISHII. *J. Pharm. Soc. Japan* 49, 475-8(1929). F. I. NAKAMURA

**Determination of glucosides.** L. ZECHNER. *Pharm. Monatsh.* 10, 90-2(1929).—The possible estn. of glucosides by chem., biochem. and physiol. methods is discussed, the latter from various angles. W. O. E.

**A study of combustion catalysis of the sulfur of organic substances.** L. BERMEJO AND A. RANCAÑO. *Anales soc. españ. fís. quím.* 27, sec. tec. 113-28(1929).—Tests were made to find a substitute for Pt foil as catalyst in the Pregl method of combustion of S in org. substances, and to det. if any relation existed between the state of the S in the org. mol. and compn. of the catalyst, but without success. E. M. SYMMES

**Potassium sulfoguaiaicolate D. A. B. 6 as reagent in the detection of methanol in alcoholic preparations.** HERMANN MATTHES. *Apoth. Ztg.* 44, 730(1929).—An account of M.'s experience with this reagent, with the suggestion that the sample prior to use be purified by soln. in  $\text{H}_2\text{O}$  (1 g. in 50 cc.) and evapn. to dryness on the steam bath, otherwise the color tests obtained may prove misleading. W. O. E.

**Iodometric determination of thioisemicarbazide.** A. GAFFRE. *J. pharm. chim.* [8], 9, 19-23(1929).—See C. A. 23, 2676. E. H.

**Lactic acid tests.** H. V. ARNY AND MARGUERITE C. DIMLER. *J. Am. Pharm. Assoc.* 18, 459-62(1929).—All of the tests for lactic acid described in the literature so far as they could be found were tried. The most satisfactory was the resorcinol test of Brauer (C. A. 14, 2772). A method was devised which combines shaking out with  $\text{EtOAc}$  and application of the Brauer test. Shake the prepn. twice with 20 cc. of pure  $\text{EtOAc}$ . Wash the mixed solvent with 5 cc. of  $\text{H}_2\text{O}$  and with 5 cc. of dil.  $\text{H}_2\text{SO}_4$ . Filter the washed solvent through a dry filter and evap. the filtrate on a water bath. Weigh the sirupy residue as lactic acid. Dissolve the residue in 5 cc. of a 1% resorcinol soln.

and layer over  $\text{H}_2\text{SO}_4$ . On standing for 2 min. with gentle rotation a red color develops. L. E. WARREN

**A new reaction of citric acid and its salts.** VICTOR ARREGUINE. *Semana méd* (Buenos Aires) 36, 173-4(1929); *Bull. soc. chim. biol.* 11, 242-5(1929).—From 3 to 4 cc. of a dil. soln. is oxidized by a 4%  $\text{KMnO}_4$  soln., the citric acid being converted into acetonedicarboxylic acid. Add 0.1 g. resorcinol and then slowly  $\text{H}_2\text{SO}_4$  until a red color appears. Cool and shake out several times with  $\text{Et}_2\text{O}$ , add to the  $\text{Et}_2\text{O}$  10 cc.  $\text{H}_2\text{O}$  and some drops of  $\text{NH}_3$ . An intense blue fluorescence is produced if more than 1:1000 parts of citric acid was present in the original soln. The reaction is based on the formation of  $\beta$ -hydroxycoumarinacetic acid. A. E. MEYER

**The factors in the estimation of starch by the iodine method.** E. LÉPIK. *Mitt. Lebensm. Hyg.* 20, 79-88(1929).—The size of the starch particles in the disperse stage depends upon the warming temp., the time of heating and the pressure. The pptn. of the starch-iodide is greater when the particles are small. At higher temp. this pptn. is accelerated if the starch is pure. Impurities hinder the reaction. A pressure over 3 atm. has an inhibitory effect. Certain growths, such as that of *Phytophthora infestans* in potato tubers, will lessen the pptn. It has been found best to use I in  $\text{CaI}_2$  soln. as the precipitant. RUSSEL C. ERB

New data on saturnism (KOHNS-ABREST) 13.

EVERS, NORMAN AND ELSDON, G. D.: **The Analysis of Drugs and Chemicals.** London: Chas. Griffin and Co., Ltd. 349 pp. 25s. net.

STAUDINGER, HERMANN: **Anleitung zur organischen qualitativen Analyse.** 2nd ed., revised and edited by Walter Frost. Berlin: J. Springer. 144 pp. M. 6.60.

## 8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

**Selected bibliography of minerals and their identification.** OLIVER BOWLES. *Bur. Mines, Circ.* 6148, 4 pp.(1929). E. H.

**Utilizing staining methods in the identification of minerals.** R. F. HEAD AND A. L. CRAWFORD. *Eng. Mining J.* 127, 877; *Bur. Mines Repts. Investigations* No. 2032, 3 pp. (1929).—H. and C. have developed a method for the differential coloring of minerals chiefly of value in the rapid examn. of crushed ores, concentrates and tailings. The most serviceable test so far developed is a distinguishing test for  $\text{PbSO}_4$  and  $\text{PbCO}_3$  based upon staining with sol. chromates. Bright yellow coatings of equal intensities are produced upon cerussite and anglesite when the mineral grains are treated with a cold satd. soln. of  $\text{K}_2\text{Cr}_2\text{O}_7$  for 15 min. Anglesite in the presence of cerussite is chromated by cold aq. soln. contg. 2%  $\text{K}_2\text{Cr}_2\text{O}_7$  and 0.5%  $\text{NaOH}$  for 1 min. Cerussite in the presence of anglesite is chromated in 1 min. by a cold 1% soln. of  $\text{CrO}_3$ . L. T. FAIRHALL

**Microchemical tests in the identification of opaque minerals.** H. E. MCKINSTRY. *Econ. Geol.* 22, 830-43(1927); cf *C. A.* 22, 4084.—The application of microchem. tests to samples obtained from polished ore sections is discussed. Tests have been checked and are summarized for Ag, As, Sb, Bi, Ni, Co, Fe, Pb, Cu, Te and Zn. E. J. R.

**A lead ore consisting of native lead, leadhillite and lithargite.** EARL V. SHANNON. *Econ. Geol.* 22, 826-9(1927).—A sample of native Pb from near Hailey, Idaho analyzed: Pb 98.66, Ag. 0.33, Cu 0.07, Fe 0.94, Zn trace, Hg, As, Sb none, sum 100.00%. Crusts around the native Pb were detd. to be lithargite, while a whitish material surrounding the latter was identified as leadhillite. A few grains of native Ag also were present. ELLIOTT J. ROBERTS

**Experiments bearing on bornite-chalcocite intergrowths.** G. M. SCHWARTZ. *Econ. Geol.* 23, 381-97(1928).—Upon heating natural bornite-chalcocite intergrowths to 225-400° and quenching, the specimens showed no trace of the intergrowths. One contg. 15% bornite resulted in a completely homogeneous phase while one contg. about 50% lost all evidences of intergrowth and the larger masses faded into one another. On reheating and cooling the specimens very slowly, the intergrowths could be reproduced. Upon heating and slow cooling of specimens low in bornite (3%), one of the resultant phases appeared to be "blue" chalcocite. Bornite and chalcocite therefore form a solid soln. at somewhat elevated temps. ELLIOTT J. ROBERTS

**$\text{K}_2\text{CuCl}_4\cdot 2\text{H}_2\text{O}$  as a product of the activity of Vesuvius.** F. ZAMBONINI AND G.

CAROBBI. *Ann. osservatorio vesuviano* [3], 2, 7-9(1925); *Mineralog. Abstracts* 4, 14.—The compd.  $2\text{KCl} \cdot \text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  was found on the floor of the crater of Vesuvius in 1920. It is given the mineral name *milscherlichite* after the chemist who first prepd. this compd. artificially. Optical data and a qual. analyses confirm its compn. J. F. SCHAIRER

Origin of chert and flint. W. A. TARR. *Univ. Missouri Studies* 1, No. 2, 46 pp. (1926); *Mineralog. Abstracts* 4, 48.—A collection of 21 chem. analyses shows a range in  $\text{SiO}_2$  from 63.67 to 99.47%. Small quantities of  $\text{CaCO}_3$ ,  $\text{MgCO}_3$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{H}_2\text{O}$  and carbonaceous matter are also present. T. believes that the material has been directly pptd. from sea water as colloidal  $\text{SiO}_2$  and is not an accumulation of org. remains. J. F. SCHAIRER

Observations on wood tin nodules. W. H. NEWHOUSE AND M. J. BUEGER. *Econ. Geol.* 23, 185-92(1928).—Hematite is almost universally present in wood tin nodules. The samples examd. were formed by a crustification process; the color banding cannot be ascribed to the Liesegang phenomenon, but is a deposition one, probably due to variation in Fe content of the depositing solns., or to replacement by hematite. ELLIOTT J. ROBERTS

Investigations on spinels. L. PASSERINI. *Atti accad. Lincei* [6], 9, 338-43(1929).—The spinels  $\text{MgCr}_2\text{O}_4$  and  $\text{NiFe}_2\text{O}_4$  have been obtained by calcining at about  $800^\circ$  the corresponding nitrates and hydroxides, resp. These crystallize in the cubic system. and have the structure of true spinels:  $\text{MgCr}_2\text{O}_4$ ,  $a_0 = 8.290 \pm 0.005$  A. U.,  $d. = 4.49$ ;  $\text{NiFe}_2\text{O}_4$ ,  $a_0 = 8.340 \pm 0.005$  A. U.,  $d. \text{ calcd.} = 5.37$ , ( $d. \text{ obs.} = 5.268$ ). A. W. C.

Changes in the oxidation of iron in magnetite. JOHN W. GRUNER. *Econ. Geol.* 22, 744-9(1927).—G. corrects a misinterpretation by Twenhofel (*C. A.* 22, 2726) of statements in a former paper by G. (*C. A.* 21, 3031) and discusses the results of T. ELLIOTT J. ROBERTS

Changes in the oxidation of iron in magnetite. PERCY A. WAGNER. *Econ. Geol.* 22, 845-6(1927).—A natural occurrence of "ferro-magnetic ferric oxide" in S. Africa is described and the name *maghemite* suggested for this mineral. ELLIOTT J. ROBERTS

Application of thermomagnetic analysis to the study of a few iron ores and of rust. J. HUGGETT AND G. CHAUDRON. *Chimie & industrie Special No.*, 331-4(Feb., 1929).—The results of an investigation carried out by means of the Chaudron-Forrestier recording instrument (*C. A.* 22, 4348) are given, and lead to the following conclusions: (1) thermomagnetic analysis of *magnetite* indicates the well-known transformation at  $570^\circ$ , and with heating in air shows an anomaly at about  $300^\circ$  corresponding to the superficial production of a small quantity of ordinary  $\text{Fe}_2\text{O}_3$ ; (2) *martite* and *specularite* (both  $\text{Fe}_2\text{O}_3$ ) always contain small quantities of magnetic oxide; (3) *goethite* and *lepidocrocite* both give ordinary  $\text{Fe}_2\text{O}_3$  after dehydration; (4) the same method was applied to various silicates and sulfides (the curves are given); (5) the thermomagnetic curve of rust is practically the same as that of lepidocrocite and similar to that of goethite. A. PAPINEAU-COUTURE

An amphibole of the glaucophane group. L. DUPARC. *Compt. rend. soc. phys. hist. nat. Genève* 44, 48-9(1927); *Mineralog. Abstracts* 4, 16.—An amphibole from a quartzite from the Ural shows ordinary glaucophane surrounded by a zone of material with different optical properties which is here named *pseudoglaucophane*. J. F. S.

Minerals of the pegmatites and surrounding rocks from Budislav in eastern Bohemia. RADIM NOVÁČEK. *Časopis Národního Musea* 102, 91-5(1928); *Mineralog. Abstracts* 4, 41.—The biotite-pegmatites of Budislav contain much Mn concd. as *spessartite* which contains  $\text{MnO}$  33.90 and  $\text{FeO}$  7.54%. The biotite contains 0.64%  $\text{MnO}$  and the calcite 0.80%. J. F. SCHAIRER

Minerals of Moravian pegmatites. JOSEF ŠEKANINA. *Časopis Moravského Zemského Musea* 26, 113-212(1928); *Mineralog. Abstracts* 4, 42-3.—A bibliography of 122 publications, and analyses of *tourmaline* and *andalusite* are given. J. F. S.

Contributions to mineralogy of Western Australia. E. S. SIMPSON. *J. Roy. Soc. West. Australia* 14, 45-56(1928); *Mineralog. Abstracts* 4, 9.—*Tantexenite*, a new mineral species, is described. It was found in the tinfields of Pilbara. Its compn. is  $\text{YTi}_2\text{TaO}_6$  with probably  $\text{CaTiTa}_2\text{O}_8$  and  $\text{Y}_2\text{TaO}_8$ . It differs from *euxenite* in having Ta in place of Cb. Sp. gr. = 5.4-5.9; color amber-yellow. Analyses of material from 2 localities are given. Descriptions and new analyses of *grossularite*, *spessartite*, *andradite*, *spodumene*, *cummingtonite* and *corundum* are included. J. F. SCHAIRER

Diffusion in ore genesis. ALFRED R. WHITMAN. *Econ. Geol.* 23, 473-88(1928).—W. studied the diffusion of KI through flawless marble satd. with  $\text{H}_2\text{O}$  under conditions of const. temp. and humidity. One hole in a block of the marble contained a satd. soln. of KI and other holes at various spacings filled with distd.  $\text{H}_2\text{O}$  served as detec-

tors. Quant. analyses of the  $H_2O$  in these holes furnished data from which the value of  $K$  in the equation  $\frac{\partial c}{\partial t} = K \left( \frac{\partial^2 c}{\partial r^2} + \frac{1}{r} \frac{\partial c}{\partial r} \right)$  was detd. to be 1, which is slightly greater than the same coeff. for KI in water. W. then proposes: "That diffusion is a large factor if not the major factor in the formation of metasomatic metalliferous deposits."

ELLIOTT J. ROBERTS

**Mineral association at the George gold-copper mine, Stewart, B. C.** W. V. SMITH-ERINGALE. *Econ. Geol.* 23, 193-208(1928).—Quartz and pyrite are of colloidal origin. Specularite occurs partially altered to magnetite. Arsenopyrite veins and replaces the pyrite. Chalcopyrite is contemporaneous with quartz and often replaces both pyrite and arsenopyrite. The Au is assocd. with the arsenopyrite since the Au value varies directly as the content of this mineral.

ELLIOTT J. ROBERTS

**Gold deposits of Woman, Narrow and Confederation Lakes, District of Kenora (Patricia Portion).** E. L. BRUCE. *Ontario Dept. of Mines* 37, Pt. 4, 1-51(1929).—This region is one of Pre-Cambrian rocks, predominately igneous. Au occurs in lenticular quartz veins and is the only economic mineral found.

ALDEN H. EMERY

**Geology of the Beardmore-Nezah gold area, Thunder Bay district.** GEO. B. LANGFORD. *Ontario Dept. of Mines* 37, Pt. 4, 83-108(1929).—Au accompanied by arsenopyrite, pyrite, pyrrhotite, chalcopyrite, sphalerite, galena, Cu and tourmaline occurs in quartz-filled fractures in a quartzite Fe formation and greenstone. Greenstone carrying 4% of graphite also occurs at one point, and 2 deposits of anthophyllite asbestos are reported.

ALDEN H. EMERY

**Huronian gold mine, Moss Township, District of Thunder Bay.** R. J. WATSON. *Ontario Dept. of Mines* 37, Pt. 4, 109-27(1929).—The region is underlain chiefly by Kewatin rocks of both basic and acid types. Two important ore deposits occur on account of the intrusion of Algoman acidic batholiths. The ore at the Tip Top mine assays Cu 5.3%, Au 0.032 oz. and Ag 0.392 oz. per ton. A quartz vein at the Huronian mine carries chalcopyrite, galena, sphalerite, pyrite, telluride and Au.

A. H. E.

**The Guanajuato mining district, Guanajuato, Mexico.** ALFRED WANDKE and JUAN MARTINEZ. *Econ. Geol.* 23, 1-44(1928).—The Ag ores are argentite, pyrrargyrite and polybasite always intergrown and assocd. with pyrite. With them Au occurs either free, combined with Ag or as a selenide. In the gang, silica, ankerite, calcite and dolomite are common, with rhodochrosite and siderite somewhat less so. The deposit is hypogene and there is no enrichment zone near the surface. The mineralizing solns. varied in compn., quartz replacing calcite pseudomorphically. They had a reducing action, W. and M. estg. that several billion tons of a red conglomerate have had their  $Fe^{+++}$  reduced to  $Fe^{++}$ .

ELLIOTT J. ROBERTS

**The ores of Potosi, Bolivia.** WALDEMAR LINDGREN and J. G. CREVELING. *Econ. Geol.* 23, 233-62(1928).—The genesis of the Ag-Sn ores of Potosi is probably as follows: a rhyolite porphyry intrusion fractured on cooling and allowed mineral bearing aq. solns. to ascend, depositing pyrite, quartz and cassiterite at 200-300°, and later tetrahedrite, andorite, ruby-silver and jamesonite at 100-150°. An analysis of andorite, which occurs as filling between quartz crystals, showed when cor. for impurities (quartz and Fe): Pb 21.12, Ag 13.12, Cu 0.83, Sb 40.67, As 0.49, S 23.77%, corresponding nearly to  $PbAgSb_5S_7$ .

ELLIOTT J. ROBERTS

**A genetic comparison of the Michigan and Bolivian copper deposits.** JOSEPH T. SINGEWALD, JR. *Econ. Geol.* 23, 55-61(1928).—The essential difference between these native Cu deposits and other Cu deposits is not in the character of the mineralizing solns. but in that of the rocks in which deposition took place. The native Cu deposits occur in rocks which originally contained  $Fe_2O_3$  and which now are bleached. The  $Fe_2O_3$  pptd. Cu from the solns. and was itself reduced.

ELLIOTT J. ROBERTS

**Technic of the investigation of iron ores.** FREDERIGH F. OSBORNE. *Econ. Geol.* 23, 442-50(1928).—In etching polished specimens of Fe ores it was found advantageous to confine the etching fluid to a limited area by contg. it in a 6-15 mm. length of 9 mm. Pyrex tubing cemented to the surface. A Pt heating coil immersed in the soln. may be used to heat the reagent in the tube. Magnetite is etched by HCl, HF,  $H_2SO_4$  and acid  $KMnO_4$ ; ilmenite, by HF; hematite, by HCl (though not always); spinel, by none of the above reagents.

ELLIOTT J. ROBERTS

**Lake Savant area, district of Thunder Bay.** E. S. MOORE. *Ontario Dept. of Mines* 37, Pt. 4, 53-82(1929).—Fe, Au, Cu, Pb, Zn and Ni have been found in this area. The magnetite and Au are of no economic importance.

ALDEN H. EMERY

**Platinum-bearing nickel-copper deposits on Lower Shebandowan Lake, District of Thunder Bay.** R. J. WATSON. *Ontario Dept. of Mines* 37, Pt. 4, 123-49(1929).—The rocks are all pre-Cambrian, mostly igneous. Only one mineralized zone seems

worthy of development: a Ni-Cu deposit on Discovery Bay and claims to the west. Sulfide replacements in peridotite schist and assoc. acid intrusions have been found along a zone a mile long and 100 ft. wide. The ore averages Cu 2 and Ni 3%, with a max. of Cu 16 and Ni 20%, also contg. 0.15 oz. of Pt metals per ton. Pyrite, chalcopyrite, pyrrhotite, polydymite and magnetite occur; Ni only in the sheared peridotite. There have probably been 2 periods of deposition.

ALDEN H. EMERY

**The origin of nickel silicates at Webster, N. C.** CLARENCE S. ROSS, EARL V. SHANNON AND FOREST A. GONYER. *Econ. Geol.* 23, 528-52(1928).—Analyses of 7 samples of nickeliferous vermiculite from Webster show 2-11% NiO. Analyses of 4 Ni minerals of the serpentine group show 15.56, 12.08, 2.57 and 4.20% NiO, resp. Analyses of pure vermiculite and some of the same pure vermiculite after treatment with  $\text{NiCl}_2$ -NaCl soln. at  $110^\circ$  for 1-2 months in a sealed tube showed that the vermiculite had taken up 12.52% NiO by replacement of MgO. Analyses of 6 samples of olivine from N. C. show a NiO content of 0.34-0.44%, while bronzite, green diopside and chromite show no NiO. Assoc. secondary minerals show about 0.2% NiO. Conclusion: The original magma from which the olivine crystd. contained NiO but that from which the other primary minerals crystd. did not. Also, the solns. altering the olivine were not Ni-bearing but during replacement most of the Ni from the olivine was carried over into the replacing mineral. Residual soil near Webster contained about 2% NiO, showing a concn. from the original olivine and serpentine about equal to the concn. of  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ , much MgO and  $\text{SiO}_2$  being lost. Partly weathered dunite also shows about 2% NiO, without a corresponding increase of  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$  or loss of  $\text{SiO}_2$  and MgO. This indicates that NiO has been taken up from solns. descending through the material, probably by base-exchange with MgO in Mg silicates.

ELLIOTT J. ROBERTS

**Newly found bauxite deposits in the Otranto District, Italy.** C. CREMA. *Miniera ital.* 13, 165-6(1929).—Analyses show as high as 56%  $\text{Al}_2\text{O}_3$ .

E. I. S.

**Mineralogical composition of tripoli of Kaluga district, U. S. S. R.** E. M. YANISHEVSKII. *Trans. Inst. Econ. Mineral. Met.* (Moscow) No. 42, 32-50(1929).—The diatomaceous earth of Kaluga district, which is mined in the quantity of 160-320 tons monthly, when moistened, is a sticky mass of dark gray color. The compn. of 3 dried typical samples was:  $\text{SiO}_2$  75.59-78.76,  $\text{TiO}_2$  0.27-0.94,  $\text{Al}_2\text{O}_3$  9.67-10.57,  $\text{Fe}_2\text{O}_3$  3.15-3.74, CaO 0.69-1.05, MgO 1.46-1.72,  $\text{K}_2\text{O}$  0.56-0.78,  $\text{Na}_2\text{O}$  0.27-0.54,  $\text{SO}_2$  0.11-0.29, loss on ignition 4.41-4.70%.

BERNARD NELSON

**Carbon ratios as an index of oil and gas in Western Canada.** I. W. JONES. *Econ. Geol.* 23, 353-80(1928).—The carbon ratio theory of White (C. A. 9, 1291) cannot be applied to Cretaceous coals, in particular those of western Canada, as an index to the oil and gas possibilities of the region.

ELLIOTT J. ROBERTS

**Replaceable bases in the shales and clays overlying petroliferous strata.** E. MCKENZIE TAYLOR. *J. Inst. Petroleum Tech.* 15, 207-10(1929).—T. previously developed a theory (C. A. 23, 2024) for the formation of petroleum from a study of shales and clays overlying oil-bearing sands, which postulates that Ca clays underwent base exchange when submerged in sea water, becoming Na clays; were lifted out of the sea, came in contact with fresh water, and were hydrolyzed; bacteria, working in the alk. medium and under anaerobic conditions, broke down org. matter and the decompn. products accumulated, not being able to escape through the clay. Twenty-three samples of shales from Trinidad, Pechelbronn and Mexico have now been examd. for  $p_H$  value and replaceable bases. The  $p_H$  values and the uniform predominance of replaceable Na over replaceable Ca show that the clays have in fact undergone base exchange with NaCl and have hydrolyzed by coming in contact with fresh water.

**Essexite-thermalite-monzonite plutonic rocks from the Kaiserstuhl and their relation to its geological structure.** J. SOELLNER. *Mitt. Badisch. Geol. Landesanstalt* 10, 1-93(1928); *Mineralog. Abstracts* 4, 45; cf. C. A. 22, 4421.—This elaborate petrographic and geologic paper includes 5 new rock analyses.

J. F. SCHAIRER

**A hydrothermal origin of corundum and albitite bodies.** ESPER S. LARSEN. *Econ. Geol.* 23, 398-433(1928).—L. opposes the theory that albitites and plumasites were formed by the desilication of pegmatites due to reaction with the ultra-basic

wall rock. His arguments are: (1) The width of the reaction zones is greater than with ordinary pegmatites and is greater than one would expect. (2) The minerals of the reaction zones (biotite, anthophyllite, actinolite and talc) indicate a hydrothermal rather than an igneous origin. (3) The minerals of the albitites and plumasites, especially the latter, are not such as would be expected from the desilication of a pegmatite or the reaction of a pegmatite with an ultrabasic rock; *i. e.*, under magmatic conditions,  $\text{Al}_2\text{O}_3$ , if present in amts. sufficient to form corundum in quantity, would unite with  $\text{K}_2\text{O}$  present to form leucite, etc. (4) The amt. of material that must be removed from a pegmatite to make an albite rock or an albite corundum rock seem excessive; *i. e.*, quant. calcns. show that at least 74% of the material of a normal pegmatite would have to be removed to form an albite, or 65% to form a plumasite contg. 25% corundum. (5) There is no relation between the width of the border zones and the width of the albite or plumasite. In the Penna. area examd. by L. the reaction zones are always 6-18 in. wide whether the albite body is 5 ft. across or entirely absent. (6) The material added to the border zone is quantitatively very different from the material taken from the pegmatite. Calcns. based on a reaction zone 1 ft. thick of the av. compn. show that this zone could be formed by the albitization of a layer of pegmatite 16.8 cm. wide and made up of 43% each of albite and orthoclase and 14% quartz, and would leave only 7 cm. of albite rock, or, in other words, a dike of albite 6 in. wide would have the reaction zones on each side 12 in. wide. A hydrothermal origin of the deposits and reaction zones avoids all these objections and also accounts for all the phenomena explained by the desilication of pegmatites.

ELLIOTT J. ROBERTS

**Hydrothermal alteration of serpentine.** FRANCIS G. WELLS. *Am. J. Sci.* [5], 18, 35-52(1929).—W. treated olivine with solns. of  $\text{Na}_2\text{CO}_3$ ,  $\text{NaHCO}_3$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{HCl}$ ,  $\text{NaCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{KCl}$ ,  $\text{FeCl}_3$ ,  $\text{AlCl}_3$ ,  $\text{HF}$ ,  $\text{NaF}$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{NaHSO}_4$ ,  $\text{NaOH}$ ,  $\text{SO}_2$ ,  $\text{CO}_2$ , water glass,  $\text{Na}_2\text{B}_4\text{O}_7$ , freshly pptd.  $\text{SiO}_2$  and  $\text{H}_2\text{O}$  under different pressures (1-301 atm.) and temps. (0-620°), and for varying times (1-15 days). In no case was olivine altered to serpentine, though it always dissolved to some extent, the soln. showing  $\text{SiO}_2$  and usually  $\text{MgO}$ . However,  $\text{MgCO}_3$ , Na silicate and  $\text{H}_2\text{O}$  will react to form serpentine. Under exptl. conditions olivine is more insol. than serpentine. Either the presence of constituents usually not assumed to be present alters the relative solubilities of olivine and serpentine, or higher temps. are necessary. W. believes the latter is the case.

ALDEN H. EMERY

**Birbirite, a new rock.** L. DUPARC, E. MOLLY AND A. BORLOZ. *Compt. rend. soc. phys. hist. nat. Genève* 44, 137-40(1927); *Mineralog. Abstracts* 4, 46.—A new rock from the Abyssinian plateau is described petrographically. The dunite has been altered to a compact brown quartzite ( $\text{SiO}_2$  88.20,  $\text{Fe}_2\text{O}_3$  9.01,  $\text{Cr}_2\text{O}_3$  0.86, etc.) here called *birbirite*. Pt is found in small quantity in the laterite covering the dunite and birbirite. Analysis gave: Pt 79.48, Os-Ir 1.41, Ir 0.82, Rh 0.75, Pd 0.49, Au 0.49 and Fe 16.50%.

J. F. SCHAIERER

**Origin of the siliceous Mowry shale of the Black Hills region.** WM. W. RUEBY. U. S. Geol. Survey *Prof. Paper* 154-D, 153-70(1929).—The Mowry shale is a thin member of hard platy shale in the lower part of the Upper Cretaceous series of the northern Rocky Mountain States. It was derived from the alteration of volcanic ash by long exposure to sea water, from which the dissolved silica was pptd. by decay-ing org. matter.

ALDEN H. EMERY

**Experimental work on red bed bleaching.** W. D. KELLER. *Am. J. Sci.* [5], 18, 65-70(1929); cf. *C. A.* 20, 3672; 22, 3869.—Analyses of rock and lab. expts. are given to prove that bleached spots in red beds are caused by reduction of  $\text{Fe}_2\text{O}_3$  and removal subsequent to such reduction.

ALDEN H. EMERY

**The origin and composition of the sediments of the Black Sea.** SILVIO VARDABASSO. *Ann. scuola ing. Padova* 4, 309-14(1929).—The analysis is given of a sample of sludge removed from the bottom of the Black Sea 100 miles northeast of the entrance of the Bosphorus. The material was viscous, of greenish gray color and of penetrating odor. On drying at 110° it lost 71.16%  $\text{H}_2\text{O}$ . The powder thus obtained was mainly composed of Al silicates, which in the original sample were present in colloidal state. The mech. analysis yielded 4.70% of fine sand just perceptible to the naked eye, the rest was composed of particles of smaller size. The powder contained: material insol in acids ( $\text{SiO}_2$  and insol. silicates) 60.45,  $\text{Al}_2\text{O}_3$  13.21,  $\text{Fe}_2\text{O}_3$  5.87,  $\text{CaO}$  4.94,  $\text{MgO}$  0.47, loss on ignition ( $\text{CO}_2$ , S,  $\text{H}_2\text{O}$ , org. substances) 14.16%. S (detd. separately) was 6.80%; no  $\text{MnO}$  and  $\text{P}_2\text{O}_5$  were present. The pungent odor was due to an opalescent liquid, which could be extd. from the powder by means of  $\text{Et}_2\text{O}$ . Its b. p. was higher than 150°; it was assumed to be a thio compd. of the aliphatic unsatd. series. Examin. under the microscope revealed the presence of the following minerals arranged in order

of their decreasing frequency: quartz, calcite, orthoclase, plagioclase, muscovite, chlorite, talc, biotite, tourmaline, zircon, rutile, apatite, epidote, titanite, hornblende, diopside, spinel. No pyrite was present. Fragments of diatoms, radiolaria, etc., were found occasionally.

G. SCHWOCH

**Preparation of sedimentary materials for study.** CLARENCE S. ROSS. *Econ. Geol.* 23, 334(1928).—Acetone is recommended in place of  $\text{CCl}_4$ , etc., for diluting methylene iodide in heavy liquid sepn., because the methylene iodide may be recovered by merely washing out the acetone with  $\text{H}_2\text{O}$ .

ELLIOTT J. ROBERTS

**Composition of peculiar clinkers found in snags after forest fires.** DUANE T. ENGLIS AND W. N. DAY. *Science* 69, 605-6(1929).—Peculiar greenish, rock-like clinkers sometimes found in hollow snags after forest fires have been suspected of being of meteoric origin, and even of being the cause of forest fires. Three samples from western hemlock snags and the wood from a living tree have been analyzed. The clinkers though from different localities all have the same approx. compn. On comparing the analysis of the wood and that of the clinker from the same locality by using the  $\text{K}_2\text{O}:\text{P}_2\text{O}_5:\text{K}_2\text{O}:\text{SO}_4$ , etc., ratios, very close agreement in compn. was obtained. The greenish color is due to Mn in the manganate form. Their meteoric origin has been disproved, as has the possibility of their starting forest fires.

LOUIS WALDBAUER

**The chemical investigation of Trinidad well waters and its geological and economical significance.** J. S. PARKER AND C. A. P. SOUTHWELL. *J. Inst. Petroleum Tech* 15, 138-82(1929).—The deposits in which oil is found in Trinidad were brought down from the South American continent by a river system flowing to the northeast. The types of deposit in which the oil occurs are varied and irregular both vertically and laterally. Minor faulting in the structures also contributes to the difficulty of understanding sub-surface conditions and interpreting the facts given by well-water analysis. The detn. of Ca, Mg, Cl,  $\text{SO}_4$ ,  $\text{CO}_3$  and  $\text{HCO}_3$  in the Trinidad well waters is necessary; Na, with K, can be calcd. with enough accuracy for the purposes of correlation. All the Trinidad waters thus far examd. contained  $\text{HCO}_3$  or a mixt. of  $\text{HCO}_3$  and  $\text{CO}_3$ , and the amts. of these radicals form the basis for comparison of the waters. The I content is also distinctive for certain fields, though the sea water contains no I. It was detd. by oxidizing the concd. and acidified  $\text{H}_2\text{O}$  with  $\text{H}_2\text{O}_2$ , collecting the I in  $\text{CHCl}_3$ , and estg. it colorimetrically or by titration. Trinidad well waters are usually colored, from pale yellow to dark brown. This is in the majority of cases due to naphthenic acids, but does not appear to be always the result of contact with oil. Color should form a convenient means of comparing such waters. Sp. gr. if taken uniformly at about  $80^\circ\text{F}$ . can be used to compute total solids. Three systems obtain for reporting results of well-water analyses: the ionic system in which the ions are reported as mg. per l. or parts per million; the combination system, in which the ions are combined hypothetically, acidic with basic; and the Palmer system of combining the ions into "primary" and "secondary salinity" and "primary" and "secondary alkalinity," and plotting the 4 points as a small and characteristic graph for each water. In the Parker system percentages by wt. of the several ions found are plotted upward additively from the base line and concn. in g. per l. horizontally. Each ion is thus represented by a rectangle. Alternate rectangles are blacked in. The order followed was  $\text{CO}_3$ ,  $\text{HCO}_3$ , Cl, Na and Ca + Mg +  $\text{SO}_4$ ; or if  $\text{SO}_4$  was a large amt., it was plotted separately, followed by Na and Ca + Mg. The chem. variations in the Trinidad waters are so small as to make it difficult to correlate them usefully with the geological data. Yet it is certain that differences between upper and lower waters in a Trinidad structure can be established by chem. analysis, yielding information which will be a guide to the driller if, for instance, a water breaks into the well. The thorough study which has been given to the waters of certain areas in Trinidad could now give place to simple tests calcd. to bring out such differences as have been proved to exist. But in new developments it would again be necessary to make the more complete analyses till the situation in general was understood.

EMMA E. CRANDAL

**Estimates of the ages of the Whin sill and the Cleveland dike by the helium method.** V. S. DUBEY AND ARTHUR HOLMES. *Nature* 123, 794-5(1929).—Emphasis is laid on the importance of age estn. in igneous rocks by the improved technic for measuring very small quantities of He. The He contents of the Whin sill,  $36 \times 10^{-6}$  cc. per g., and of the Cleveland dike,  $11 \times 10^{-6}$  cc./g., correspond to ages of  $182 \times 10^6$  years and  $26 \times 10^6$  years, resp.

## 9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

**Ore treatment by flotation process.** A. ROCHELT. *Z. Oesterr. Ing. u. Architekten Ver.* 81, No. 15-16, 135-8(1929).—The ore-treatment plant and methods used in recovery of Cu and Ag of Kogl mines near Brixlegg in Tyrol are described. E. I. S.

**Ore dressing and flotation.** ANON. *Mining J.* (London). *Special Equipment* No. 43-6, 48(July 13, 1929).—Coarse and fine crushing, wet gravity concn. methods, sintering processes, dust recovery, electromagnetic ore sepn., mill power transmission and submerged combustion are briefly considered with names of equipment manufacturers.

ALDEN H. EMERY

**Effect and composition of flotation reagents.** W. PETERSEN. *Metallbörse* 19, 1322-3, 1380-1, 1434-6, 1490-1(1929).—Prior to 1921 the choice of flotation agents was empirical; with Perkins patent (C. A. 15, 663) the correlation of chem. structure and behavior as flotation reagent began. These substances are classified as (1) foaming agents, chiefly slightly sol. materials with polar-nonpolar constitution leading to the formation of monomol. layers with H<sub>2</sub>O and consequent changes in surface tension; (2) collecting agents, with S'' or N''' or similar elements in lower valence; (3) flotation poisons, like metallic cations of high valence, salts of certain metals, cyanides, hydroxides, ferri- and ferrocyanides, arsenates and arsenites, sulfites, sulfates, thiosulfates, colloidal slimes, etc.; and (4) antidotes, such as CaO, Na<sub>2</sub>CO<sub>3</sub>, protective colloids, etc. Many illustrations of the above are discussed.

W. C. EBAUGH

**Theory of concentrating table.** W. LUYKEN. *Metall u. Erz* 26, 297-301(1929); cf. C. A. 23, 2399.—A critical analysis of expts. (reported by others) on concn. with Wilfley tables, etc., leads to the conclusion that the detg. factor in this type of ore dressing is the sp. gr. of the materials used, and not the sizes of the particles present.

W. C. EBAUGH

**Concentrating auriferous pyrite.** FRIED. W. FREISE. *Metall u. Erz* 26, 301-6(1929).—In a rotating roaster pyrite of 0.6-1.4 mm. diam. began roasting between 350° and 390° that of 2.5-5.6 mm. between 390° and 430°, and that of 40 mm. between 465° and 480°. If As be present roasting starts at a lower temp. than indicated above, the order with other metals is As, Sb, Bi, Fe and Cu. The formation of SO<sub>2</sub>, As<sub>2</sub>O<sub>3</sub> and As<sub>2</sub>S<sub>3</sub> began between 300° and incipient redness. Trials of Cl upon Au showed that volatilization began at 100-122°, increased rapidly to 300° (7%), moderately to 450° (9%), rapidly to 650° (15%) and 850° (27%). Expts. with Au-contg. pyrite ores showed that it made no difference whether NaCl is added before or after grinding. If a preliminary roast be given before NaCl is added the Au losses on roasting are less. In all roasting slow heating (not sudden changes of temp.) is best. Pyrites whether rich or poor in Au suffer the same proportional losses with the same treatment. When other metals are present a chloridizing roast is influenced as follows: Ag and Pd are indifferent; Pb causes very small losses; Sb, Zn and Cu cause much greater Au losses.

W. C. EBAUGH

**The treatment of mixed (bulk) concentrates from base-metal sulfide ores.** W. E. HARRIS. Canada Dept. of Mines, Mines Branch. *Rept.* No. 695, 154-7(1929).—Concentrates of a Zn-Cu ore are roasted in an atm. of steam, thus reducing the formation of *ferrites* to a min. The calcines are leached with H<sub>2</sub>SO<sub>4</sub>, pptg. SiO<sub>2</sub> and Fe in the vat. By agitation and boiling the SiO<sub>2</sub> forms a granular filter bed for the pregnant solns. After filtration, the Zn-Cu soln. is electrolyzed, 60-70% of the Cu being recovered. The acid formed is neutralized with ZnO, recovered from the residue, and the remaining Cu is pptd. with Zn dust. After filtering the soln. is purified from Ni, Co, Cd and the last Cu traces with Hg and Zn dust in hot soln. Zn is finally recovered by electrolysis.

ALDEN H. EMERY

**Converting 70,000 tons of concentrates a month into blister copper.** S. M. SOUPCOFF. *Mining Congress J.* 15, 428-30(1929).—The reverberatories of Utah Copper's

Garfield smelter have capacities of 800 to 1000 tons per day. Flow of material through roasters, reverberatory furnaces, converters and casting machines is described.

**Concentrator of the Phelps Dodge Corporation Morenci Branch.** A. CROWFOOT AND D. C. BARNARD. *Mining Congress J.* 15, 448-54(1929).—Cu ore is concd. E. I. S.

**The iron and manganese ores of the Nordmark District.** N. H. MAGNUSSON. *Sveviges Geol. Undersökning* No. 13, 5-98(1929).—The general geology, origin of the Fe deposits and the formation of new minerals through metasomatic alteration are discussed. The Fe ore is poor in Mn. Only in 2 mines have Mn ores been worked; the ore is chiefly hausmannite. E. I. S.

**Lagunillas iron ore and its metallurgical value.** S. WAESSMAN. *Pub. Direccion general Minas, Geol. e Hidrologia* (Buenos Aires) No. 51, 3-4(1929). E. I. S.

**Improvements in milling practice at the Utah Copper Company plants.** H. S. MARTIN. *Mining Rev.* 31, No. 4, 7-10(1929). E. I. S.

**Leaching waste dumps at Tyrone.** E. M. SAWYER. *Mining Congress J.* 15, 538 9(1929).—Spraying was found inadequate. High-pressure hose application was successful. Baled factory scrap is most satisfactory for pptg. base. Scrap consumption is 1.30 lb. per lb. of Cu recovered. E. I. S.

**Early history of lead smelting in the west.** R. WALLACE. *Mining Rev.* 31, No. 5, 7-15(1929). E. I. S.

**The Clifton smelter of the Phelps Dodge Corporation.** I. J. SIMCOX. *Mining Congress J.* 15, 455-8(1929).—Roasting temps. are maintained by an occasional oil boost. Anode treatment is detailed. Low-S oil is used to facilitate low-S content in Cu. E. I. S.

**Historical summary of gold, silver, copper, lead and zinc produced in California, 1848 to 1926.** J. M. HILL. U. S. Bur. of Mines, *Econ. Paper* No. 3, 22 pp.(1929). E. J. C.

**Platinum and gold nuggets.** S. F. ZHEMCHUZHNIK. *Ind. Australian and Mining Standard* 81, 334(1929).—Notes on examn. and study of microstructure and phys. properties of 14 Pt nuggets of different sizes and from various sources, in connection with problem of genesis of Pt; Au and Ag nuggets were also studied, to investigate possibilities of formation from natural solns. E. I. S.

**The Snowflake tin silver vein.** V. DOLMAGE. *Can. Mining J.* 50, 626-7(1929).—The vein developed is in the Revelstoke dist. It is a quartz vein in carbonaceous argillites, sometimes graphitic and with small bodies of Ag-Pb-Zn ore; Sn occurs as stannite. Selected ore assayed 26.65% Sn. E. I. S.

**The aluminum problem in Poland.** LUDWIK WASILEWSKI. *Przemysl Chem.* 13, 93 100, 120 6(1929); cf. *C. A.* 23, 360.—This is largely a survey of economical and technical conditions which have a bearing on the development of an Al industry in Poland. A. C. ZACHLIN

**Control features new type of open-hearth furnace.** NORMAN F. HINDLE. *Foundry* 57, 502-5, 568-71(1929).—A description is given of the new 25-ton open-hearth steel furnace of the American Steel Foundries at Indiana Harbor, and various features of its construction and control devices are illustrated by photographs and drawings. DOWNS SCHAFF

**The electric operation of blast-furnace hoists.** C. H. S. TUPHOLME. *Iron & Steel Ind. and Brit. Foundryman* 2, 309-13(1929). E. H.

**Cupola-furnace slags.** MATTHES MIKLAU. *Die Giesserei* 16, 534-7(1929).—General discussion. HANS DUUS

**Fuel economy in the cupola.** N. D. RIDSDALE. *Iron & Steel Can.* 12, 179-80(1929). E. H.

**Pulverized coal in steel furnaces.** WM. O. RENKIN. *Iron Age* 124, 155-6(1929). E. H.

**Formation of insoluble zinc compounds during roasting.** H. R. HANLEY, CHARLES Y. CLAYTON AND DAVID WALSH. *Am. Inst. Mining Met. Eng. Tech. Pub.* No. 220, 17 pp(1929).—Progressively increasing amts. of powd. pyrite were mixed with powd. marmatite and the mixt. was roasted for 8 hrs. at 625° and 900°. At these temps. about 0.25 g and 0.45 g. Zn, resp., were rendered insol. per g. of free Fe. The combined Fe, as the marmatite constituent, always renders Zn insol. to the extent of 0.584 g. per g. of combined Fe. The generalized effectiveness of free Fe as pyrite to form insol. Zn is about 40-50% of the combined Fe when roasting at 625° and 80-90% at 900°. E. M. S.

**The sand blast in iron foundries.** II. J. McLACHLAN AND C. A. OTTO. *Iron & Steel Ind. and Brit. Foundrymen* 2, 327-30(1929). E. H.

**Test bar results approximate properties in casting.** JOHN W. BOLTON. *Foundry* 57, 509-12, 572-5(1929).—Information from many sources is compiled in the study of the influence of mfg. practice on given grades of cast Fe and the relationship of test bar results to engineering properties of the casting. DOWNS SCHAART

**The carbon content of high-grade gray castings made by steel additions in the cupola, and properties depending upon it.** KARL EMMEL. *Die Giesserei* 16, 605-12 (1929).—Contrary to the accepted idea that the best gray castings must contain less than 3% C, extensive tables of analyses and phys. test results are given for metal obtained on regular runs (not selected values) made by steel addns. to cupola charges, these show that a C content of 3% or slightly more gave optimum values for tensile strength, certainty of quality desired, etc. It is claimed that this special iron has now reached a stage of development entitling it to the full confidence of the iron foundler and ultimate user. W. C. EBAUGH

**Air in the cupola furnace.** A. LEHMANN. *Die Giesserei* 16, 613-6(1929). The importance of air as a part of the charge in a cupola furnace, the neglect often shown this factor, and means for measuring it (Taylor tube, Venturi meter, etc.) are discussed. W. C. EBAUGH

**The theory and application of regenerative principles in the steel industry.** II. T. J. McLOUGHLIN. *Blast Furnace and Steel Plant* 17, 1044-7(1929); cf. C. I. 23, 3425. E. H.

**The elimination of sulfur from the alloys of iron.** K. GIERDZIEJEWSKI. *Foundry Trade J.* 40, 465-6(1929).—A discussion of the methods of desulfurizing by means of slags. C. I. READ

**Volatility of oxides of lead, cadmium, zinc and tin.** FEISER. *Metall u. Erz* 26, 269-84(1929).—Oxides of metals contained in Pt boats or crucibles were heated in elec. furnaces to known temps. while a current of gas, free from reducing agents—especially CO—was passed over the mass; from the loss of wt. of the oxides the volatility was calcd. Tables and curves report results. The oxides are volatile at about the following temps.: PbO 750°, CdO 900°, ZnO 1300° and SnO<sub>2</sub> 1350°. A decrease of vapor pressure of PbO was caused by SiO<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub> and SnO<sub>2</sub>. The b. p. of PbO is 1472°, and the sublimation temp. of CdO is 1380-1390°. The small vaporization of PbO from mxts. with ZnO points to the existence of compds. between these substances. Al<sub>2</sub>O<sub>3</sub>, CaO, MgO and ZnO did not lower the vapor pressure of PbO. The influence of sintering upon the volatility of PbO was due to the diminution of the surface of the PbO exposed to the high temp. Trials at volatilizing PbO from converter flue dusts showed that it could be done, but that even 2-5% of SiO<sub>2</sub> in the flue dust made removal of the last traces of PbO very difficult. W. C. EBAUGH

**Autogenous welding serving the chemical and process industries.** T. M. JASPER. *J. Am. Welding Soc.* 8, No. 6, 12-7(1929).—Fundamental requirements of welding as applied to containers and pressure vessel construction for oil, chem. and other process industries are outlined. E. I. S.

**Tests of metal arc welds.** ANDREW VOGEL. *Gen. Elec. Rev.* 32, 332-9(1929).—Tests were made to det. unit stresses for design purposes and uniformity and reliability of the welds. The results establish unit stresses of 2000 lb. per linear in. for 1/4 in. welds, 2500 lb. per linear in. for 1/16 in. welds, and 3000 lb. per linear in. for 3/8 in. welds, and show that welding is uniform in strength and entirely reliable. H. STORITZ

**Hammer-welding aluminum and its alloys.** H. REININGER. *Metallhse* 19, 1378-80, 1433-4(1929); cf. C. A. 23, 2408.—Welding Al with gas flames is not effective with pieces of 30-40 mm. thickness, and hammer-welding is resorted to when other methods cannot be used. Pure Al welds more easily than some of its alloys. Hammer-welded Al has only 2/3 to 3/4 the tensile strength of the original metal, whereas autogenous gas-welding gives practically the original value. With many com. Al-alloys about 85% of the tensile strength can be obtained. W. C. EBAUGH

**A new fitting for welded pipe.** E. G. LUENING. *Ind. Eng. Chem., News Ed.* 7, No. 14, 3-4(1929). E. J. C.

**X-ray pattern of metallic crystals.** G. B. DEODHAR. *Nature* 123, 909(1929).—Ring patterns are obtained for Au, Ag and Sn foils. I. J. PATTON

**Reflection of ultra-violet rays from metallic surfaces in relation to their micro-structures.** HAJIME KORÔ. *Mem. Coll. Sci. Kyoto Imp. Univ.* 12A, 81-96(1929).—In Cu-Ag, Cd-Bi, Zn-Cd, Cu-Ni and Mg-Zn alloys a min. in intensity curve for reflection of ultra-violet and visible rays occurs in general at the eutectic, except that Cu-Ag alloys shows no min. for ultra-violet rays. A max. occurs where a compd. is formed. In the case of solid soln. a break or max. in the curve appears. A. P. SACIS

**Röntgen ray investigations in shop practice.** C. KANTNER AND A. HERR. *Metall-*

*wirtschaft* 8, 575-8, 602-6(1929).—Types of shop tests carried out with Röntgen ray app. in the expt. station of the Deut. Reichsbahn Ges. at Wittenberg are discussed and illustrated. Of special value are tests for faulty castings, improper welding, heat treatment, detecting flaws that have been repaired, etc. W. C. EBAUGH

**The effect of annealing upon the solidus temperature of alloys.** J. H. ANDREW AND H. M'NEIL. *J. Roy Tech. Coll.* (Glasgow) 2, No. 1, 64-72(1929).—A wide sepn. between the liquidus and solidus in an alloy system is due to supercooling on freezing, or lack of uniformity of the solid on melting. A bronze contg. 7.89% Sn was annealed to give different degrees of uniformity, and thermal analyses then showed that, as the uniformity increased, the solidus temp. rose greatly, the melting range narrowed, and the liquidus also rose somewhat. Alloys must therefore be thoroughly annealed if an accurate equil. diagram is to be plotted from m.-p. detns. Grain refinement in alloys occurs only during heating through a transformation, and is due to diffusion occurring during the heating. Some typical  $\alpha$ - $\beta$  structures are discussed, and the theory is proposed that  $\alpha$  may exist separately, but with the same space-lattice as  $\beta$ , in the single-phase alloy which first appears on solidification from the melt. G. F. C.

**Effect of section and various compositions on physical properties of cast iron.** R. S. MACPHERRAN. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 12-8.—Tensile and Brinell hardness detns. on test bars ranging from  $1\frac{1}{4}$  to 4" in diam. cast from 3 different types of gray Fe, show: (1) the effect of increasing the section on hard low-Si gray Fe and soft high-Si gray Fe is to materially and progressively lower the tensile strength; (2) the removal of extra stock in the hard low-Si gray Fe and the soft high-Si gray Fe is progressively accompanied by loss of hardness; (3) the high-test Fe under the cooling conditions described has practically the same Brinell hardness throughout the section; (4) the tensile strength of the high-test Fe tends to fall off as the section is increased or as the cooling is retarded, though not to the extent shown by the other 2 types. DOWNS SCHAAF

**Static strength of plain and alloy cast iron.** F. B. COYLE. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 23-9.—A series of constitutional and strength diagrams are presented showing the effect of compn., particularly the elements Ni and Cr, on the tensile strength and structure of cast Fe. DOWNS SCHAAF

**Heat treatment of cast iron.** F. B. COYLE. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 70-4.—The structure, aging and growth of cast Fe, as affected by temp., are briefly described for the following temp. ranges: (1) up to 425°; (2) from 425° to the crit. range; (3) from the critical range to the m. p. DOWNS SCHAAF

**Classification of gray iron alloys.** J. W. BOLTON. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 3-11.—In order to classify gray iron alloys the author discusses the following factors which influence the properties of gray iron castings: (1) chem. compn.; (2) structural and mech. make up of charge; (3) melting process; (4) thermal and mech. history; (5) design and workmanship. DOWNS SCHAAF

**Impact testing of cast iron.** H. BORNSTEIN. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 44-9.—A comparison is made of the impact test results on a "regular Fe" and a "high-strength Fe." DOWNS SCHAAF

**Wear testing of cast iron.** A. L. BOEGEHOLD. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 50-60.—The work of many investigators on wear testing of cast Fe is reviewed, and a brief description is given of a wear test conducted on an automobile engine constructed of individual cylinders of 4 different kinds of cast Fe, which, after running 20,000 miles, demonstrated that the kind of cylinder Fe used had no influence upon the result because of good lubrication between the piston and the cylinder. DOWNS SCHAAF

**Some interrelationships in gray iron metallurgy.** J. W. BOLTON. *Foundry Trade J* 40, 449-54(1929).—The correlation of test results to engineering properties of cast-iron castings is discussed, and numerous curves are plotted showing the effects of various factors on strength, the relationship of the vol.-area ratio to cooling rates, etc. A classification of cast irons based on C and Si contents is given. The raw materials in the charge, melting practice, and thermal and mech. treatment are also important factors influencing the properties of cast iron. The rate of cooling is very important, and is controlled by various factors, especially the vol. to surface ratio of the casting. Results of tests on different-sized castings of one grade of cast-iron are given in detail. Examples are given showing how the strengths of com. castings can be calcd. from test-bar results by allowing for the influence of the various factors discussed above. Test-bars should have similar cooling rates to those of the castings represented. The Fremont shear test on small specimens cut from castings is not generally reliable. The

form and amt. of graphite are most important. Dissolved gases in cast iron do not have serious effects.

**Mechanical properties of cast steel and forged steel of large dimensions.** ZIRO TUZI AND OOSI KADITA. *Bull. Inst. Phys. Chem. Research* (Tokyo) 8, 335-55; *Abstract Ed.* 2, 46(1929).—Two samples of rudder stock, 10 in. in diam. and 18 ft. long, 1 of cast steel and 1 of forged steel, were subjected to chem. analysis, mech. tests, and microscopic examn. The results show much heterogeneity in cast steel pieces and indicate that forged steel is far more reliable.

**Tensile tests on rods and wires of the same iron.** J. MUIR. *J. Roy. Tech. Coll.* (Glasgow) 2, No. 1, 5-11(1929).—Tensile tests of 2 grades of very soft steel rods, 0.2 in. in diam., were made just past the yield point, then the specimens were heated in boiling water and the tests repeated. This procedure gave progressively higher yield points. Rods annealed at various temps. from 500 to 850° were tested in the same way, and the extensions at the yield point for the annealed rods were much greater than for the originals, though the yield point values were similar. No explanation for this difference was found by microscopic examn. In the tests of wires 0.024 in. in diam. annealing was necessary to give any yield point.

**The magnetostriction of various steels.** J. S. RANKIN. *J. Roy. Tech. Coll.* (Glasgow) 2, No. 1, 12-9(1929).—A short review of previous work on magnetostriction is given. An app. is described for measuring the very small changes in length, with oscillating thermionic valves; and its method of use is explained. The changes in length corresponding to various magnetic forces and inductions are plotted for 6 steels, 2 of them contg. Ni. The length change decreased with increasing C content (0.17 to 0.80%) for a given magnetizing force. The steels contg. Ni gave a different form of curve.

**Fundamentals underlying the heat treatment of steel.** O. W. ELLIS. *Can. Chem. Met.* 13, 195-200(1929).

**Blast-furnace gas in heating steel.** A. J. EBNER. *Blast Furnace & Steel Plant* 17, 1031-3(1929); cf. *C. A.* 23, 3792.

**Utilization of mineral oils for thermal treatments of steels.** L. ROY. *Acières speciaux* 4, 171-3(1929); cf. *C. A.* 23, 3427.—R. discusses the volatility, tendency to oxidize, thermal cond. and sp. heats of various oils. By means of a graph, R. shows the speed of tempering of a piece of steel heated to 760° when immersed in a bath contg. 95 l. of liquid, the final temp. of the piece being 345°. Water gives the most rapid tempering, mineral oil the slowest, while a mixt. of 40% mineral oil and 60% cottonseed oil, cottonseed oil and fish oil occupy intermediate positions.

**Tempering changes in steels.** R. HAY AND R. HIGGINS. *J. Roy. Tech. Coll.* (Glasgow) 2, No. 1, 73-80(1929); cf. *C. A.* 22, 3613.—The elements Mo, W, Sn, P, Cr, V and Si are more sol. in  $\alpha$  Fe with body-centered lattice than in  $\gamma$  Fe with face-centered, and therefore when dissolved in Fe they decrease the temp. range in which  $\gamma$  is stable. C, Ni, Al, Cu and possibly Mn are more sol. in the face-centered than in the body-centered Fe lattice, and hence have the opposite effect, increasing the temp. range in which  $\gamma$  is stable. Ni steels, a Cr steel and a Cr-Ni steel were hardened, tempered at various temps. from 25 to 600°, and the Brinell hardness was detd. The Ni-Cr sample was the only one that showed any hardening on tempering at 125°. The fundamental process of tempering is the coalescence of finely dispersed carbide particles. Special elements may stabilize the soln. of carbides, or hinder their coalescence. By sp. vol. calcs. it is shown that the carbide is critically dispersed in steel contg. 0.60% C to obtain max. hardness.

**The normalizing of sheet steel.** W. PARKER. *Engineering* 127, 799(1929).—Sheet steel normalized in small lots in a continuous type furnace has superior phys. properties to box-annealed sheet since the time cycles of heating and cooling of the material are correct for obtaining uniformity in grain structure.

**The lattice-constant of quenched carbon steels.** SINKITI SEKITO. *Science Repts. Tōhoku Imp. Univ.*, 1st Ser. 18, 69-77(1929).—Exptl. results are given to show that the axial ratio of the tetragonal lattice appearing on the surface of quenched C steel diminishes with increasing depth, finally attaining the value 1. On annealing quenched C steel the tetragonal lattice changes immediately into the body-centered cubic form without assuming some intermediate axial ratio. The axial ratio of the tetragonal lattice increases with the C content, as well as with the quenching temp.

**The distribution of the austenite in specimens of quenched carbon steels.** KÔTARÔ HONDA AND ATOMI ÔSAWA. *Science Repts. Tōhoku Imp. Univ.*, 1st Ser. 18, 47-58(1929).—A series of steels contg. 0.3, 0.6, 0.9, 1.5 and 1.7% of C, were quenched in H<sub>2</sub>O from a high temp. After quenching each piece was carefully cut into 2 parts and

hardness detns. were made over the sectional area as well as the outer surface of the specimens. By comparing the lines of the x-ray patterns taken at different points on the surface, it is shown that the amt. of retained austenite in quenched steels is greater in the outer layer than in the inner.

DOWNES SCHAAP

**Recent investigations concerning the hardening of steel.** ERICH SCHEIL. *Arch. Eisenhüttenw.* 2, 375-88 (1928).—By graphs information concerning cooling curves, expansion, sp. vol., temp.-pressure changes, magnetic properties, hardness, lattice parameters, elec. resistance, etc., is presented, and the conclusion drawn that the transformation of austenite into martensite occurs more completely when cooling is brought about more rapidly. Under these circumstances the necessary tension is present.

W. C. EBAUGH

**Properties of materials at high temperatures. The strength at elevated temperatures of low-carbon steels for boiler construction.** R. G. BATSON AND H. J. TAPSELL. Dept. Sci. Ind. Research. *Eng. Research Special Rept. No. 14*, 41 pp. (1929).—At stresses corresponding to the proportional limit and with temps. between 500° and 600° "creep" proceeds at an extremely slow rate at first but gradually increases and leads to final fracture. Results are given for normalized 0.17% C steel and cold-drawn 0.10% C steel annealed at 650°.

H. C. PARISH

**High-carbon copper steels.** A. F. STOGOV AND V. S. MESKIN. *Arch. Eisenhüttenw.* 2, 321-31 (1928).—Previous investigations of Cu steels of low-carbon content are reviewed briefly. The properties of steels of 0.69-1.22% C and 1.19-5.07% Cu are studied. Cu increases the magnetic properties of steel; the crit. point is lowered (to 640° for 5% Cu) and it causes a large temp. hysteresis but without affecting the C content of the pearlite. Quenched and tempered Cu steel shows a high % of elongation and hardens with relatively good ductility and compressive strength. As Cu increases the coercive force of heat-treated steel, it may be assumed that Cu in the steel is not present in the free state.

R. D. BUMBACHER

**Uses of copper bearing steel for structural purposes.** F. P. TURNER, *et al.* *Am. Ry. Eng. Assoc. Proc.* 30, 1015-7 (1929).—Information collected indicates increased use of Cu bearing steel for steel cars, tie plates, track spikes, smoke stacks, boilers, culvert pipe, flashings, ventilators, fencing, structural steel, sash, power line supports, flood light towers and overhead electrification structures for railway tracks.

R. C. B.

**Nickel and nickel-chrome steels, forged and rolled; properties and applications.** ANON. *Aciers spéciaux* 4, 217-9 (1929).—A review.

A. J. MONACK

**Magnetic alloys of iron, nickel and cobalt.** G. W. ELMEN. *J. Franklin Inst.* 207, 583-617 (1929).—After a brief historical sketch of the work done on ferromagnetic alloys since 1913, the properties peculiar to the permalloys (Fe-Ni alloys with more than 30% Ni) and the permalvars (Ni 45%, Co 25%, Fe 30%) are discussed at length. The effects of varying the proportions of the various components, annealing, quenching, etc., on the initial permeability, max. permeability, hysteresis loss, intrinsic induction, resistivity, etc., are presented in a series of three-dimensional plots. The effects of various heat treatments are considered in detail and an explanation is offered on the theory of segregation, although it is recognized that this does not account for the high permeabilities at low fields. The possibility of the formation of a compd. such as FeCO<sub>3</sub> is also considered. A brief account of the applications of these alloys in telephone circuits is included.

W. W. STIFLER

**X-ray investigation of iron and nitrogen alloys.** ATOMI OSAWA AND SHUJIRO IWAIZUMI. *Science Repts. Tôhoku Imp. Univ.*, 1st Ser. 18, 79-89 (1929).—See C. A. 23, 2408.

DOWNES SCHAAP

**X-ray analysis of chromium-nitrogen systems including an investigation of the constitution of ferrochrome metals containing nitrogen.** RAGNAR BLIX. *Z. physik. Chem.*, Abt. B, 3, 229-39 (1929).—An x-ray analysis of a series of Cr-N products prepd. by heating electrolytic Cr in a stream of NH<sub>3</sub> at 800° reveals the existence of 2 intermediate phases in the Cr-N system. One of the phases remains homogeneous over a wide concn. (atomic) range including 33% N. The Cr atoms of this phase are in a hexagonal-close-packed lattice and the N atoms are probably arbitrarily imbedded in the voids of the lattice. The lattice size increases with increasing N content from  $a_1 = 2.747$  A. U.,  $a_2 = 4.439$  A. U., to  $a_1 = 2.770$  A. U.,  $a_2 = 4.474$  A. U. The other phase corresponds to CrN and has the cubic NaCl structure, with a lattice parameter of 4.140 A. U. In the photographs of a ferrochrome metal with 60.3% Cr, 2.4% N, 2.0% Si and 0.21% C there appeared among other patterns those of the hexagonal Cr-N phase so that it is probable that the N of ferrochromes exists in this phase.

H. W. WALKER

**Report of Committee B-2 on non-ferrous metals and alloys.** WILLIAM CAMPBELL. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 19, 34 pp.; cf. C. A. 22, 2912;—

Results are given of phys. and chem. studies of die-casting alloys by cooperating labs. Rept. also discusses statistical analysis, radiographic examn. of die-castings and die-casting progress in Europe.

H. C. PARISH

**The resistance of chrome-nickel thermoelements to (corrosive attack by) metal melts.** R. HASE. *Z. Metallkunde* 21, 200-3(1929).—Chrome-nickel and Ni thermocouples of 5-mm. wire were introduced into a melt of 87% Cu, 6% Sn and 7% Zn at a temp. of 1040° for periods of 12 sec. Photomicrographs are given of cross-sections of the wires after 5-, 10-, 25-, 50- and 100-fold immersions. The Ni was much more rapidly attacked than the chrome-nickel, diminishing greatly in cross-section without showing internal structural changes. The chrome-nickel began to show strong corrosion after a 50-fold immersion which appeared to follow fine cracks originating in the surface. This type of thermocouple will endure 100 or more immersions. A melt of 63% Cu, 37% Zn was very much more corrosive, the character of the attack remaining the same as before. Zn is doubtless the cause of the corrosion. It is concluded that such bored-out wires with a surface as free as possible from cracks hold the greatest promise for long-life thermoelements to be used in casting practice.

ROBERT F. MEHL

**An x-ray study of copper which showed directional properties on cupping.** ARTHUR PHILLIPS and GERALD EDMUNDS. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 48, 10 pp.—In sheets of Cu reduced 70 and 99% the common orientation was characterized by a predominance of dodecahedral planes in the surface and a 353 direction along the rolling axis. A preferred orientation was found in the annealed sheet which formed ears when cupped. Cu which drew without ears showed random orientation. There is evidence that preferred orientations in Cu, annealed at the usual temps., may be often attributed to excessively high rolling reductions. It is suggested that the formations of ears in drawn Cu may be avoided by limiting reductions to approx 65% and annealing at temps. of 500° to 600°.

H. C. PARISH

**Hardness relationships and physical properties of some copper alloys.** C. H. DAVIS and E. L. MUNSON. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 47, 12 pp.—For the several Cu alloys in the alpha phase of binary and ternary systems, the relationship changes progressively from that of pure Cu to that of the alloy of lowest Cu content. The tensile strength-elongation and hardness-elongation relationships are detd. by the compn. and previous history of the material. The tensile strength-hardness relationship of an annealing series of an alloy is a single line.

H. C. P

**Stress cracking in tubing.** CLEMENT BLAZEY. *Metal Ind.* (London) 34, 555-8 (1929).—The distortion undergone by brass tubing contg. 29% Zn and 1% Sn in cold drawing was studied, and the effects on inner and outer crystals of the tube are described. The tendency to crack from internal stresses was greater when the tube was hollow-sunk than when it was drawn normally over a mandrel so that the wall thickness was reduced. The relation between the changes in external and internal diam., and the tendency to crack, is discussed. Frictional drag did not seem to be an important factor so that the exact shape of die does not matter.

G. F. COMSTOCK

**The twinning plane in a zinc crystal.** M. ICHIHARA. *J. Soc. Mech. Eng. Japan* 31, 1043-54(1928).—Twin lamellas on basal, prismatic and diagonal crystallographical planes were observed and the direction of twin lamellas was calcd. graphically. Graph results were identical with observed values. Conditions for producing large single Zn crystals by strain method were investigated.

E. I. S

**The (solid) solubility of copper in silver.** M. HANSEN. *Z. Metallkunde* 21, 181-4 (1929).—Twelve Ag-Cu alloys varying in compn. between 0.68 and 10.22% Cu were prep'd. by melting "purest" Ag and electrolytic Cu in a graphite crucible under charcoal. These were hammered and rolled, then annealed (in 1 cm.<sup>2</sup> pieces) in an elec furnace under an atm. of CO<sub>2</sub>. Oxidation could be detected only in the outer 2 mm layer. After a 20-hr. anneal at 750° alloys with 2.55, 4.57 and 6.16% Cu were quenched after heating for 10-15 min. at a series of increasing temps. and inspected for incipient melting in order to det. the solidus curve. The solid soly. of Cu in Ag was detd. at temps. of 750, 700, 650, 600, 500, 400, 350, 300 and 250°. The alloys were heated at 750°, cooled to quenching temp., then quenched and inspected, except for the detn. of the soly. at the temps. of 350° and less when the alloys were quenched from 700° or 750° and tempered; the soly. at 400° was detd. by both methods with identical results. The soly. was found to be 1.7% Cu from room temp. to 300° increasing to about 9.0% at the eutectic temp. (779°), with an accuracy of 0.5% Cu from 400° upward and a greater accuracy at lower temps.

ROBERT F. MEHL

**Silver solders.** R. R. SEUMAN. *Welding Eng.* 14, 64-5(June, 1929).—Comments on characteristics of Ag solders as a group are made including melting temps., vibration, shock, soundness, corrosion resistance, elec. cond. and speed in using.

E. I. S.

**X-ray study of the internal transformations in silver-zinc alloys.** A. ROUX AND J. CURNOT. *Compt. rend.* **188**, 1399-1401 (1929).—The x-ray crystal patterns of a Ag-Zn alloy contg. 30.23% Zn were detd. in 3 states, annealed at 500°, quenched after heating 10 min. at 500° and quenched and tempered at 210° for 1 hr. The presence of 2 constituents with cubic lattices in the annealed alloy was recognized, but of only one in the quenched alloy. In the quenched and tempered alloy the pattern indicated that the lattice of the single constituent was tetragonal, being deformed by pptn. of the second constituent in small quantity. The microscopic evidence supported these deductions.

G. F. COMSTOCK

**Acid resisting alloys of lead.** MASAO SANO. *Repts. Imp. Ind. Research Inst. Osaka, Japan* **10**, No. 3, 57 pp. (1929).—The following alloys of Pb were prepd: (I) Pb-Sb (4.15-18.10% Sb), (II) Pb-Ni-Sb (0.30-4.05% Ni; 4.40-13.0% Sb) and (III) Pb-Ni (amt. of Ni used was < 5%). The acid-resisting properties of the alloys were studied by immersion in H<sub>2</sub>SO<sub>4</sub>. In I (concn. of acid was 25-80% at 20°, and 15 and 45% at 30° for 7 days) acid corrosion was lowest at the eutectic and highest with 8% Sb. In II (concn. of acid 5-50% at 30° for 7 days; Sb kept at 10% and Ni varied) acid corrosion was inversely proportional to the amt. of Ni. In I acid corrosion was higher at high temp., but in II it was less affected by high temp. In general acid corrosion was higher the more dil. the acid. In II (Ni kept at 2% and Sb varied) acid corrosion was inversely proportional to the amt. of Sb and a min. at 18%. The phys. properties of the above alloys were also studied.

F. I. NAKAMURA

**The texture of cast metals and alloys.** E. SCHMID AND FOSTER C. NIX. *Metallwirtschaft* **8**, 651-4 (1929).

W. C. EBAUGH

**Cast aluminum alloys for pistons.** H. REININGER. *Metallbörse* **19**, 1209-11, 1266 7 (1929).—Tables and illustrations show the compn. and properties of many European and American alloys. In spite of the greater hardness of cast-Fe pistons the life of Al pistons is only about 10-15% less, a factor more than compensated for by their smaller wt. Fe, Ni and Mn give Al alloys of excellent properties; Pb is undesirable; Si alloys are not as suitable for pistons as for other parts of motor vehicles; Zn is not as useful as Fe, Ni or Cu; nor is Sb helpful; Mg can be alloyed to 3.5%, increasing hardness to about twice the extent of Cu. It is an important component, of recent Al pistons. Heat treatment of cast-Al pistons does not seem to yield permanent improvement, due to high motor temp.

W. C. EBAUGH

**Soldering of aluminum to other metals.** L. QUACK. *Chem.-Tech. Rundschau* **44**, 17 (1929).—Al has previously been connected with other metals by welding or soldering, but solders used have been unsuitable and the resulting joints insufficiently resistant to water. Inhoffen has introduced a new mobile, refractory solder which can be used at comparatively low temp. Joints made by this develop no leaks on 14 days exposure to conductivity water. The compn. is not given.

E. PICKERING

**Fatigue resistance of some aluminum alloys.** J. B. JOHNSON AND T. T. OBERG. *Proc. Am. Soc. Testing Materials* **1929** (preprint) No. 43, 5 pp.

H. C. PARISH

**Aluminum alloys for pressure die castings.** SAM TOUR. *Proc. Am. Soc. Testing Materials* **1929** (preprint) No. 51, 18 pp.—Zn in Al alloys causes hot shortness. Ni is usually an advantage and seldom causes trouble. Si added to a no. of Al alloys seems to decrease shrinkage and increase ductility at elevated temps. In many alloys, Fe in proper quantities seems to decrease hot shortness and increase strength at elevated temps. Excessive Fe sometimes causes hot shortness and brittleness. 0.10% Mg seems to decrease fluidity, increases shrinkage, causes some additional hot shortness and decreases strength at elevated temps. Sn causes hot shortness. Practically all alloy additions to Al, except Sn, Zn and possibly Si in some cases, increase hardness as it affects machineability. Si and Sn deaden the luster, while Cu, Ni and Fe improve it.

H. C. PARISH

**Light alloys of high strength.** R. CAZAUD. *Aciers spéciaux* **4**, 174-84 (1929).—A review.

A. J. MONACK

**The corrosion of iron in sodium chloride solution.** W. VAN WÜLLEN-SCHOLTEN. *Arch. Eisenhüttenw.* **2**, 523-30 (1929).—Electrodes of (a) smooth, and (b) rough Fe were dipped into NaCl soln., the outer circuit was completed through an ammeter. In a quiet soln. the smooth electrode became negative; moving the electrodes or stirring the soln. caused reversal of polarity. By measuring single potentials involved and applying Nernst's theory of the cell to det. the e. m. f. produced, it is shown that Fe(OH)<sub>2</sub> and Fe(OH)<sub>3</sub> formed upon the electrodes must be considered not as sep. phases, but as solid solns. When O is admitted to the two poles it alters the potential of both, but the relationship Fe<sup>++</sup>/Fe<sup>+++</sup> does not remain alike for the two poles. Measurements confirmed theoretical values. Similar explanations are offered for the rusting

of Fe; the previous condition of the surface, both as to its phys. state and the  $\text{Fe}^{+++}/\text{Fe}^{++}$  ratio in the rust present, det. the future course of the reaction upon it. W. C. E.

**The corrosion and the rusting of alloyed and unalloyed cast iron.** P. KÖRZSCHEKE AND E. PIWOWARSKY. *Arch. Eisenhüttenw.* 2, 333-40(1928).—In grey cast iron the form of segregation or the quantity of graphite within the usual limits has no influence on corrosion in acids or salt solns. Si, lower than 1.5% for HCl and lower than 3% for AcOH, decreases the corrodibility; a 3% Si cast iron is strongly attacked in caustic solns. Addns. of Ni up to 6% have no pronounced effect on the acid corrosion while it improves the resistance to caustic solns. One % Cr decreases acid corrosion. Neither 0.7-3.0% nor 6% Ni nor 1% Cr show marked influence on rusting in salt solns. A Cu content up to 0.9% does not impart resistance to acid corrosion but with increasing Cu content the resistance toward NaCl solns. is much greater. The resistance of grey cast iron to weather and atmospheric attack is increased by 25% for an addn. of 0.3-0.4% Cu. R. D. BUMBACHER

**Corrosion of cast iron.** H. O. FORREST. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 35, 61-70.—Corrosion rates of samples of cast Fe made by different processes have been made at M. I. T. by rotating small samples, cut from standard 8" pipe, in Cambridge water and measuring the loss in wt. over time intervals up to 300 days. The av. corrosion rate for the irons tested approximated 0.01 in. per year, the av. deviation from the mean value of all samples being only 7%. DOWNS SCHAAF

**The influence of corrosion accelerators and inhibitors on fatigue of ferrous metals.** F. N. SPELLER, I. B. McCORKLE AND P. F. MUMMA. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 41, 12 pp.; cf. *C. A.* 22, 2732. Under corrosion-fatigue, the endurance decreases as the chloride contents increase. In water with low saline contents even a slight external influence causing localized corrosion reduces the corrosion-fatigue endurance limit, even of stainless steels, decidedly either with or without inhibitors in the corroding soln. The strength of inhibitor required to prevent failure increases with chloride concn. Stress is essential but probably plays only a minor part directly in accelerating corrosion. H. C. PARISH

**Application of corrosion-resisting materials to railroad electrical construction.** R. P. WINTON. *Et. al. Am. Ry Eng. Assoc. Proc.* 30, 482-5(1929).—Al alloys, Cr alloy steel, Cu-coated steel, Ni alloys, Cu brass, bronze and Al, Cd and Mg-Si bronze are considered. R. C. BARDWELL

**Intercrystalline corrosion of duralumin.** F. M. BONDOR. *Aviation (Aeronautical Eng. Sect.)* 26, No. 24, 99-100(1929).—Protection of duralumin airplane parts against intercrystalline and common corrosion is discussed.  $\text{CaCl}_2$  used on fields promotes intercryst. corrosion. Resistance to corrosion is affected by the method of quenching. Various methods of protecting duralumin are outlined. E. I. S.

**Corrosion. A problem in protective coatings.** F. N. SPELLOR. *Iron & Steel Can.* 12, 177-8(1929); cf. *C. A.* 23, 3199. E. H.

**Combating corrosion in a chemical plant.** E. JENSEN. *Ind. Eng.* 87, 315-8 (1929).—Experience of Parlin, N. J., plant of Hercules Powder Co., one of whose chief products is nitrocellulose, in protecting equipment and buildings from corrosion. E. I. S.

**General properties of boiler tubes with special reference to the relation between corrosion and fuel.** M. KINUKAWA. *J. Fuel Soc. Japan* 8, 649-63(1929); Abstract sect. *Ibid* 71-3.—A lecture. F. I. NAKAMURA

**Briquetting ores.** EUGEN A. A. GRÖNWALL. Fr. 656,567, June 27, 1928. See Brit. 294,470 (C. A. 23, 1860).

**Rare earth ores.** DEUTSCHE GASGLÜHLICHT AUER-GESELLSCHAFT M. B. H. Fr. 654,465, May 19, 1928. Rare earth ores contg. Zr and Ti are decomposed with  $H_2SO_4$  in a closed cycle, the sulfates obtained being transformed to the oxides by roasting, the  $SO_2$  and  $SO_3$  produced by the roasting with the necessary O or air being passed over finely ground fresh ores which are then decomposed with  $H_2SO_4$ .

**Centrifugal grinder for ores, etc.** MINES DOMANIALES DE POTASSE D'ALSACE. (Lehner Robert, inventor). Fr. 652,921, Apr. 16, 1928.

**Washer for ores.** ADRIANUS C. HOUDIJK. Ger. 478,183, Dec. 12, 1926.

**Treatment of titaniferous ores.** NATIONAL METAL AND CHEMICAL BANK, LTD. Ger. 478,136, May 18, 1926. The powd. ore with its natural moisture content or after addn. of moisture is treated with oleum and the reaction is allowed to proceed without the application of heat.  $TiO_2$  may be obtained from the product by dila. with water.

**Table concentrator for ores.** ALBERT H. STEBBINS. U. S. 1,720,862, July 16. Structural features.

**Froth-flotation ore concentration.** C. H. KELLER (to Minerals Separation, Ltd.). Brit. 301,832, Dec. 6, 1927. Flotation is effected with use of an agent obtained from a hydrocarbon, S, a metal and Cl, e. g., (a)  $C_6H_6$ , S chloride and Zn (b)  $C_6H_6$ , S and  $AlCl_3$ , or (c) *n*-heptane, S chloride and Zn.

**Tank and belt apparatus for "desliming" and classifying ore pulps.** JAMES R. WRIGHT. U. S. 1,720,810, July 16. Structural features.

**A method and apparatus for dressing slime.** THEODOR FRANZ. Ger. 477,657, Oct. 1, 1924.

**Treating solutions obtained from ores after chlorination roasting.** HANS NEUMARK. U. S. 1,720,138, July 9. Cu is pptd. by cementation with Fe, sulfates are removed (suitably by cooling and adding  $CaCl_2$ ) and Zn is pptd. from the resulting soln. by treatment with gases contg.  $H_2S$ .

**Copper extraction from ores.** ANGLO AMERICAN CORP. OF SOUTH AFRICA, LTD. Brit. 301,859, Dec. 7, 1927. Cu occurring in the form of Cu silicate is extd. with an ammoniacal solvent such as  $NH_4$  carbonate. Various details are described. Cf. C. A. 23, 1860.

**Apparatus for separating and concentrating gold from sand by panning.** LEWIS W. BANEY and ERNEST G. MESSER. U. S. 1,719,958, July 9. Structural features.

**Treating tin-bearing materials.** H. L. SULMAN and H. F. K. PICARD. Brit. 301,553, June 13, 1927. Sn is extd. from ores such as cassiterite and from other Sn-bearing materials such as scrap tinned steel by treatment with a sulfidizing agent such as S vapor at a temp. (suitably 750–850°) which will convert the Sn to a sulfide sol. in a suitable reagent such as HCl or alkali or alk. earth metal sulfide solns. and the sulfide is then leached out. Reducing agents may also be used and numerous details and modifications are described.

**Chlorinating tin-bearing materials.** E. A. ASHCROFT. Brit. 302,851, April 5, 1928. Sn-bearing materials such as ores or concentrates contg. cassiterite, slags, alloys or residues are treated with  $ZnCl_2$  or  $FeCl_2$  in the presence of a reducing agent such as Fe or Zn powder or carbonaceous material preferably contg. a little iron. Temps. of 600–900° are suitable and the  $SnCl_2$  formed may be run off or distd. or extd. by lixiviation. Numerous details and examples are given.

**Zinc.** HENRY E. COLEY. U. S. 1,721,373, July 16. See Fr. 647,768 (C. A. 23, 2414).

**Zinc.** GÉORGES LESIC. Fr. 656,917, July 2, 1928. Zn is obtained from calamine earths by submitting the earths to the action of  $FeCl_3$  to obtain  $ZnCl_2$ , and treating the latter with  $MgO$  to obtain  $Zn(OH)_2$  which is dehydrated to  $ZnO$ . The  $MgCl_2$  is reconverted to  $MgO$  by heating it in the presence of  $CaCl_2$  and steam.

**Ore-roasting furnace.** NOEL T. WELLMAN (to General Chemical Co.). U. S. 1,721,265, July 16. A furnace suitable for roasting pyrites to produce  $SO_2$  is constructed

so that the ore is fed to the uppermost of a series of superposed hearths and S is fed by an interconnected device to one of the lower hearths in order to enrich the gas produced.

**Cupola furnace.** P. MARX. Brit. 301,739, Dec. 3, 1927. Oil burners are fitted outside the furnace instead of within the air tuyère, in a furnace otherwise generally similar to that described in Brit. 300,559 (C. A. 23, 3893).

**Gas-burner construction suitable for metallurgical furnaces.** HENRY M. HEVN (to Surface Combustion Co.). U. S. 1,721,484, July 16.

**Gas-fired furnace for heating metal billets.** H. A. DREFFEIN. Brit. 302,651, Dec. 19, 1927. Structural features.

**Gas-fired furnace for heating metal plates.** H. A. DREFFEIN. Brit. 302,652, Dec. 19, 1927. Structural features.

**Gas-fired furnace for annealing or melting metals.** R. GUNKA. Brit. 302,711, Sept. 21, 1927. Structural features.

**Furnace for annealing articles of copper or other non-ferrous metals.** D. BRIDGE & Co., LTD. and W. SHAW. Brit. 302,779, Nov. 7, 1927. Structural features.

**Rotary reducing furnace for use in iron and steel manufacture.** PIERRE J. PEYRACHON. U. S. 1,720,055, July 9. Structural features.

**Apparatus for recovery of sulfur dioxide from pyrites roaster gases, etc.** F. L. WILDER, E. MORRIS, E. SCHIFF and E. S. KING. Brit. 302,386, Sept. 15, 1927. Gas is entrained in a descending column of liquid such as water and released from the liquid subsequently by reduction of pressure.

**Grinding mill for basic slag.** G. POLYSIUS A.-G. Ger. 478,057, May 13, 1928.

**Apparatus for mixing and grinding foundry sand.** A. LENTZ. Brit. 302,664, Dec. 19, 1927. Structural features.

**Molds and molten metal pourers for founding.** JOHANNES WILBERZ. Ger. 477,587, Sept. 25, 1926. Details are given.

**Molds for casting zinc and aluminum alloys.** FELTEN & GUILLEAUME CARLS WERK A.-G. Brit. 302,604, Dec. 16, 1927. An alloy of Fe with about 30% Ni is used for making molds for casting alloys which it is desired shall solidify slowly.

**Ingot mold.** W. H. RAMAGE (to Valley Mould & Iron Corp.). U. S. 1,721,490, July 16. Structural features.

**Ingot mold.** EARL C. SMITH (to Central Alloy Steel Corp.). U. S. 1,720,383, July 9. Structural features.

**Hot-top construction (with an integral brick lining) for ingot molds.** WILLIAM H. RAMAGE (to Valley Mould & Iron Corp.). U. S. 1,721,088, July 16. Structural features.

**Mold-casting machine.** HERBERT EMMERMANN. Ger. 477,585, May 1, 1927. Details of construction are described.

**Die-casting machine.** GELSENKIRCHENER BERGWERKS-A.-G. Ger. 477,586, Oct. 7, 1926. Details are given.

**Cores for electromagnetic apparatus.** I. G. FARBENIND. A.-G. Fr. 33,993, Aug. 16, 1927. Addn. to 619,290. In making cores from metal obtained by the decomposition of carbonyl compounds, the metal is heated in a reducing atm. before being made into cores. Cf. C. A. 22, 1286.

**Magnetic cores.** WALTHER EHLERS and FRITZ FALKENBERG (to General Elec. Co.) U. S. 1,721,379, July 16. The permeability of magnetic cores formed of pressed powdered material is increased by filling hollow spaces in the core after assembly by particles of magnetic material such as colloidal Fe or Fe alloy.

**Material for magnet cores of loading coils, etc.** AUTOMATIC TELEPHONE MFG. Co., LTD. and P. N. ROSEBY. Brit. 301,784, Sept. 5, 1927. Magnet cores or similar articles are formed of powdered iron or an Fe alloy contg. Si 2-8% which is annealed in air-tight pots at about 660° and then treated with synthetic-resin varnish and air-dried while agitated. Numerous details are given.

**Hardening ferrous metals.** H. LINDHORST. Brit. 302,740, Sept. 28, 1927. Articles of iron, mild steel or iron alloys are heated to 720-820° in a hermetically closed chamber with a small quantity (up to 5%) of hardening powder (such as a mixt. of lignite or coke 50, BaCO<sub>3</sub> or other alk. earth carbonate 30 and NH<sub>3</sub> an NH<sub>4</sub> salt, urea, cyanamide, Ca cyanamide or dicyanamide 20%) which decomposes to form CO<sub>2</sub> and other gaseous products which effect the hardening. Parts of the metal which are not to be hardened may be plated with Cu. Cf. C. A. 23, 809.

**Rust-proofing iron.** SOC. ANON. DE HAUTS-FOURNEAUX ET FONDERIES DE PONT-A-MOUSSON. Brit. 301,729, Dec. 3, 1927. Metals of the Fe group are immersed in a hot soln. of phenic acid or phenols to which acids or ferrous salts may be added. An elec-

trolytic treatment may be employed, with the articles treated as anodes and Fe, Zn or other suitable metal as cathode.

**Cast-iron internal-combustion-engine tappet.** GEORGE SCHNEIDER and FREDERICK A. WELSMILLER. U. S. 1,720,353, July 9. The outer surface of the stem of a cast-iron tappet is rendered "nick-resistant" by being made of chilled hardened white iron. The interior axial body of the tappet is made of a core of soft gray iron.

**Use of cerium in refining iron and steel.** I. G. FARBENIND. A.-G. Brit. 302,574, Dec. 17, 1927. Ce (alone or in the form of a ferro-alloy) may be used together with V, Ti, Al, Ca, Mg or Si.

**Separating fine steel or iron oxide particles from mercury, etc.** B. L. NEWKIRK (to British Thomson-Houston Co., Ltd.). Brit. 302,319, Dec. 14, 1927. In sepg. minute particles of steel or Fe oxide from Hg used in a Hg-vapor power system, or in similar sepgs. of minute particles from liquid material which does not wet them, the liquid is passed through a bed of small bodies such as steel balls or gravel which are not wet by the liquid. An app. is described.

**Iron and steel castings.** W. KLEPSCH. Brit. 302,254, Aug. 10, 1927. For rendering iron or steel castings resistant to fire, acids and alkalis, they are cast in molds the sand of which is mixed with sufficient decarbonizing material to produce a superficial layer 0.3–40.0 mm. thick contg. not more than 2.6% (and preferably over 1.4%) C. The iron may contain Al, B, Cr, Co, Cu, Mg, Mn, Mo, Ni, Si, Ti, V or W.

**Process for rendering steel, wrought iron and cast iron non-rusting.** F. DE GROOTE. Belg. 356,056, Dec. 31, 1928. The metal is cleaned and immersed in a bath contg. an acid, an alkali or alk. earth salt, and one or more inert oxides.

**Steel ingot.** JOHN E. PERRY (to Valley Mould & Iron Corp.). U. S. 1,720,857, July 16. Steel ingots adapted for rolling are formed with tapered sides with the taper not to exceed 1.5% and with zones of isocrystn. comprising cupped zones with the mouths of the cups toward the small end of the ingot.

**Protecting steel tubes against corrosion in acid soils and in submerged trenches.** USINES À TUBES DE LA MEUSE. Belg. 355,406, Nov. 30, 1928. The tube is wrapped in a double envelope of jute fabric contg. a layer of CaO or other basic product. Belg. 355,945, Dec. 31, 1928 specifies applying a layer of CaO or other basic product to the tube and wrapping in jute or similar fabric.

**Protecting baths of magnesium or similar metals from oxidation.** GILBERT MICHEL. U. S. 1,720,286, July 9. The surface of the bath is covered with a protective layer such as  $MgF_2$  and the crust thus formed is covered with S. Cf. C. A. 23, 369

**Refining magnesium and its alloys.** GUSTAV PISTOR (to I. G. Farbenind. A.-G.). U. S. 1,720,436, July 9. See C. A. 23, 810.

**Alloys.** RICHARD WALTER. Fr. 656,678, May 12, 1928. Nitrides or carbonitrides of metals or of B or Si are added to metals to increase the hardness thereof. The nitrides are obtained by carburizing first by heating with powd. C or exposing to a current of hydrocarbons, and then treating with  $NH_3$ , cyanamide or carbamide.

**Alloy for steam pipe joint packings, etc.** GUSTAAF VERDICKT. U. S. 1,720,065, July 9. Pb 5, Sb 1 and Zn 0.25 part.

**Alloy for water-heating electrodes, etc.** HENRY A. BEHRENS (one-third each to Clark Nixon and Edward E. Miller). U. S. 1,720,756, July 16. An electrode which undergoes practically no electrolysis on passage of elec. current through it is formed of Sn 2–10, Cu 0.25–2.0, Pb 10–25, Bi 5–20% and Sb.

**Corrosion-resisting alloys.** SOC. ANON. COMMENTRY-FOURCHAMBAULT ET DECAZEVILLE. Brit. 302,249, Dec. 12, 1927. Alloys are formed contg. Ni 20–50, Cr 10–25, Mn 1–5, C less than 1, W 0.5–8.0 or Mo 0.2–5.0 (or W and Mo together 0.2–8.0%) and the remainder Fe. Up to 10% Co and small proportions of V and Ti also may be added.

**Magnetic alloys.** W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 302,394, Sept. 16, 1927. An alloy suitable for use as tape or wire for loading signalling conductors comprises Ni and Co with not less than 5% Mn. Up to 6% of one or more of the elements Cr, Mo, W, Si, V or Al may be added to increase the elec. resistance. Wire formed of the alloy may be heated at 900° and cooled in air. Cf. C. A. 23, 2146.

**Aluminum alloys.** D. R. TULLIS. Brit. 302,440, Oct. 12, 1927. Al alloys contg. B together with Zn 3–16, Si 1–6 and Cr 0.2–1.0% are made by adding to a bath of molten Al a Cr-Al alloy rich in Cr, then a Si-Cr alloy rich in Si, and then Zn and afterward treating the bath with  $BCl_3$  as described in Brit. 272,326 (C. A. 22, 1755). Mn may be used instead of Cr.

**Aluminum-silicon alloys.** SOC. D'ELECTROCHIMIE D'ELECTROMETALLURGIE ET

**DES ACIERIES ELECTRIQUES D'UGINE.** Brit. 302,692, Dec. 20, 1927. In making Al-Si alloys of high Al content, with use of a slight excess of reducing agent, heating is continued until the charge is exhausted, a high concn. of power is applied in the reduction zone and a low-tension elec. supply is used. The charge is preferably briquetted and may contain materials such as kaolin, alumina and petroleum coke proportioned to yield alloys contg. definite specified proportions of Al, Si, Fe, Ti and C.

**Iron-chromium-aluminum alloys.** V. B. BROWNE. Brit. 302,640, Dec. 19, 1927. Alloys such as those contg. Cr 5-30 and Al 3-10%, the remainder being iron with as low a C content as possible, are worked from the ingot by forging or rolling in a series of stages each of which is effected at a temp. lower than that of the preceding stage. Strips or wire may be thus made which are ductile and resist oxidation at high temps.

**Iron-chromium-aluminum alloys.** V. B. BROWNE. Brit. 302,644, Dec. 19, 1927. Alloys such as those contg. Cr 5-30 and Al 3-10% (the remainder being iron with as low a C content as possible) are forged or rolled from the ingot in a series of stages each of which is completed at a temp. lower than that of the preceding stage. Various details are given.

**Molybdenum alloys.** CLIMAX MOLYBDENUM Co. Fr. 656,916, July 2, 1928. A compd. of Mo, such as Ca molybdate is put in contact with molten Fe in a fusion or reduction furnace during the fusion or reduction, approx. the whole of the Mo entering the Fe as alloy. Cf. C. A. 23, 1611, 3432.

**Nickel-chromium steel alloys resistant to corrosion or staining.** W. H. HATFIELD AND H. GREEN. Brit. 302,812, Dec. 31, 1927. Alloys are described contg. Ni 11.5-13, Cr 11.5-13 and C not more than 0.2%. They are rendered ductile by heating to 950-1090° (preferably 1000-1050°) and then cooling either quickly or slowly.

**Tarnish-resisting silver alloy.** DANIEL GRAY, RICHARD O. BAILEY and W. S. MURRAY (to Oneida Community, Ltd.). U. S. 1,720,894, July 16. A material suitable for silverware comprises about 90% or more Ag and sufficient Si (suitably about 1/4-3%) to render it substantially non-tarnishing. Cf. C. A. 23, 4031.

**Alloy-steel tubes for steam boilers.** M. PETERS. Brit. 302,317, Dec. 14, 1927. Steam, water, fire and anchoring tubes of steam boilers are made of steel contg. Cr 0.2-10, Ni 0.2-8, or Mo 0.2-2%.

**Apparatus for the decomposition of hydrocarbons.** ELECTRO METALLURGICAL Co. Fr. 657,118, July 6, 1928. The app. used for the heat decompn. of hydrocarbons is made of an alloy contg. Cr 15-40, Ni 2-15, Si 0.7-3, Mn 0.7-3, C less than 1%, the remainder being Fe.

**Protecting metals.** AMERICAN MACHINE & FOUNDRY Co. Fr. 657,039, July 5, 1928. Metals are protected by coating them with Pb contg. Zn 4.5 and Al 0.5% at a temp. of about 468°, and an exterior coating of Pb contg. 2% Sn phosphide applied at 400°. The exterior coating may also contain 0.1% Pb phosphide. Cf. C. A. 23, 2926.

**Metal-spraying device suitable for applying coatings.** CHARLES M. SAEGER, JR. U. S. 1,721,092, July 16. A high-frequency induction furnace is used for melting the metal to be sprayed.

**Coating wire.** METALLDRAHTWERK KARLSHORST G. M. B. H. (Richard Winkler, inventor). Ger. 478,435, Apr. 1, 1927. Wire for elec. purposes is passed repeatedly, before coating, through a heating oven and a wiper, which may be satd. with petroleum or turpentine.

**Coating for metal molds.** ALFRED R. WILLARD (to Willard Storage Battery Co.). U. S. 1,720,356, July 9. Molds such as those used for casting Pb or Pb-Sb alloy battery grids are treated with a waterglass soln. and finely divided cork.

**Manufacture of substances formed by highly endothermic reactions, such as metallic zinc.** E. CONNERADE. Belg. pat. 356,945, Jan. 31, 1929. The roasted Zn ore and a reducing agent are introduced into a chamber surrounded by the incandescent mass of fuel of a gas producer. The producer gas is circulated through the chamber as it is formed.

**Thermic or electrothermic reduction of oxides for the production of volatile metals such as zinc.** O. DONY. Belg. 355,018, Nov. 30, 1928. Reduction is carried out below 1000° by means of a gaseous reducing agent under pressure, which permits of using ordinary metal walls, such as Fe. Condensation is effected out of contact with air in a closed app. under adjustable pressure.

**Working magnetic material.** N. V. PHILIPS' GLOEILAMPENFABRIEKEN. Fr. 657,464, July 12, 1928. Magnetic material is worked by submitting it, previously decarbonized, to a final operation during which the material partially oxidizes; this

may be carried out by decarbonizing for the greater part by heating in the presence of air or O and continuing the heating until the material is partially oxidized.

**Hollow metal articles.** FREDERICK C. LANGENBERG (one-half to Tracy C. Dickson). U. S. 1,720,368, July 9. In forming articles such as large guns, a hollow tubular body is expanded to increase its elastic limit, and a second tubular body is then placed within the first and expanded until the elastic limit of its inner layer is not materially different from that of the outer layer of the first-mentioned body.

**Porous metal bodies.** FRIEDRICH SIGMUND. Austrian 113,314, Jan. 15, 1929. Porous metal bodies are prepd. from powd. or granular metals or alloys by heating them in a non-oxidizing or reducing atm. and under continuous or intermittent pressure to such a temp. that a porous structure is obtained while avoiding the production of a liquid phase. The heating may alternatively be applied *in vacuo*. The manuf. of bodies for use in filtering and in catalytic processes is referred to.

**Pickling bath for metals.** JAMES H. GRAVELL (to American Chemical Paint Co.). U. S. 1,721,389, July 16. In baths such as those of  $H_2SO_4$  used for pickling ferrous metals, a distillate from animal material such as hair, gristle, hides, casein, flesh, ossein or gelatin is used as a combined pickle regulator and foam-producing material.

**Hardening and testing metals.** E. G. HERBERT. Brit. 301,762, Aug. 29, 1927. In hardening or testing metal articles such as gears or internal surfaces such as bores of guns (or for testing or hardening the metal balls used in the procedure), metal surfaces are bombarded with balls moving with a predetd. velocity. An app. and numerous details for conduct of the process are described.

**Heat-treating non-cementable metals and alloys.** CHEMISCHE FABRIK WEISENSTEIN GES. Brit. 302,642, Dec. 19, 1927. Metals or alloys such as copper or brass are heated in fused salt baths of thin consistency which contain oxidizable substances such as cyanides in small proportion (suitably 10% or less) which prevent scale formation or reduce scale present on the metals. The metals may be preheated in waste furnace gases or other O-free or O-low gases.

**Hard-metal composition suitable for cutting tools or wear-resisting articles.** KARL SCHRÖTER (to General Elec. Co.). U. S. 1,721,416, July 16. A sintered hard and tough metal compn. consists mainly of hard metal carbide such as W carbide and an auxiliary metal such as Co cementing particles of the carbide together and having a sintering temp. lower than the m. p. of the carbide, and comprising over 10% of the material.

**Annealing-box made of cast steel.** P. BOEL. Brit. 301,640, Nov. 24, 1927. Structural features.

**Apparatus for continuous flattening and annealing of steel strips, etc.** HARRY M. NAUGLE and ARTHUR J. TOWNSEND (to American Rolling Mill Co.). U. S. 1,721,350, July 16.

**Annealing steel strips.** HARRY M. NAUGLE and ARTHUR J. TOWNSEND (to American Rolling Mill Co.). U. S. 1,721,351, July 16. In order to effect annealing and to clean the surface of a steel strip, the strip is uniformly heated to annealing temp., the surface is deoxidized while in the heated condition, and the material is then cooled, all during a continuous passage through an app. which is described. Cf. C. A. 23, 3435.

**Annealed thorium.** W. B. GERO (to Westinghouse Lamp Co.). U. S. 1,719,975, July 9. In annealing worked bodies of refractory metals such as Th, the latter is surrounded in a hermetically sealed chamber with finely divided, chemically reactive materials such as Th powder which are inert to the metal body under treatment but are capable of combining with atm. gases within the container to form stable compds. at the annealing temp. The container and contents are then heated to annealing temp.

**Welding rod.** J. B. GREEN. U. S. 1,720,039, July 9. A ferrous welding rod or wire has a distributed S content which in the surface portion is less than 0.025% and in the center portion is more than 0.025%.

**Arc-welding electrodes.** IMPERIAL CHEMICAL INDUSTRIES, LTD. and J. H. PATERSON. Brit. 302,064, Dec. 30, 1927. Parallel wire strands which may be formed of Fe, Ni or Cu or their combinations are welded together at intervals and asbestos fibers may be inserted between the strands to act as a flux and may be soaked with  $Na_2CO_3$  soln or otherwise suitably treated to modify the properties of the electrode.

**Electric arc welding.** INTERNATIONAL NICKEL CO., N. B. PILLING and J. G. SCHOENER. Brit. 301,687, March 22, 1928. In welding Ni or its alloys such as Monel metal, preferably contg. up to 0.2% of an alk. earth metal such as Ca or Mg to render the metal malleable, the parts are subjected to fusion in an elec. arc and the malleabilizing substance is maintained in the melt so as to eliminate any S present and prevent

formation of blowholes. An electrode is used formed of Ni or Ni alloy contg. Ca or Mg and preferably also Mn, Si and C which are retained in the melt by use of a coating or core for the electrode contg. a highly reducing metal of high b. p. such as Ti or a low melting alloy of such a metal such as ferro-Ti and a metal of relatively low b. p. such as Ca (preferably in the form of Ca silicide). Numerous details and formulas are given.

**Solder.** E. EGHOLDT. Brit. 301,717, May 29, 1928. Tubes of solder are filled with a flux and deoxidizing material mixed with a substance which burns with only a small residue and renders the filling viscous so that it does not exude in excess during soldering. Glycerol and  $\text{NH}_4\text{Cl}$  may be used.

**Soldering metal.** PAUL ODAM. Fr. 657,312, Nov. 21, 1927. A metal for soldering Al consists of Al and 5-12% of Si.

## 10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

**The problem of asymmetric synthesis.** R. BOUSSET. *Compt. rend.* 188, 1407-10 (1929).—A theoretical consideration (1) of the exptl. conditions that must be fulfilled for a true asym. synthesis in distinction from a resolution of racemates, and (2) of the possibility of the transfer of dissymmetry.

JANET D. SCOTT

**Optical activity of mixtures of solvents.** I. P. KRIVOBABKO AND G. E. MUKHIN. *Ukrainskii Khim. Zhur.* 2, Sci. Pt., 331-9 (1926).—On the basis of Winther's theory of optical rotation (*C. A.* 1, 2969) the best explanation is the formation of mol. complexes of the active substances in the solns. and mixts. of solvents. The following constants were obtained in measurements of optical activity of di-Me tartrate at 25° and a concn of 0.25 g. mol. in EtOH,  $\text{C}_6\text{H}_6$ ,  $\text{CHCl}_3$ ,  $\text{PhNO}_2$  and their mixts.: EtOH,  $[\alpha]$  2.781°, —1.224°, —4.784; EtOH +  $\text{C}_6\text{H}_6$ , EtOH (%) 100, 76.76, 51.46, 25.5, 0,  $[\alpha]$  2.781°, 2.337°, 1.557°, —1.335°, —4.45°; EtOH +  $\text{PhNO}_2$ , EtOH (%) 100, 79.31, 70.78, 48.05, 29.52, 15.22, 7.61, 0,  $[\alpha]$  2.781°, 5.117°, 5.955°, 6.897°, 8.445°, 10.123°, 12.682°, 17.91°;  $\text{C}_6\text{H}_6$  +  $\text{PhNO}_2$ ,  $\text{C}_6\text{H}_6$  (%) 100, 71.74, 51.18, 33.99, 15.12, 10.33, 0,  $[\alpha]$  —4.45°, 2.114°, 6.36°, 10.46°, 14.512°, 15.574°, 17.91°. According to Winther, where the solvent and optically active substance do not combine, the action of the solvent upon the optical activity depends solely upon the difference in the internal pressure of these 2 substances. The greater internal pressure causes the depolymerization of optically active substance. The optical activity of di-Et tartrate in  $\text{H}_2\text{O}$  is positive, for the single mols. rotate positively. The optical activity in  $\text{CHCl}_3$  is negative. The mol. wt. of di-Et tartrate in  $\text{CHCl}_3$  is 235 (according to Walden) and the internal pressure of  $\text{CHCl}_3$  is less than the internal pressure of di-Et tartrate. The smaller internal pressure accounts for the assocn. of the optically active substance. Thus the assocn. may be brought in connection with the internal pressure.

J. KUCERA

**Air oxidation of hydrocarbons catalyzed by nitrogen oxides.** I. Natural gas. II. Benzene. CARLISLE H. BIBB AND HOWARD J. LUCAS. *Ind. Eng. Chem.* 21, 633-8 (1929); cf. *C. A.* 22, 4333.—Mixts. of natural gas and air, bubbled through concd.  $\text{HNO}_3$  and then heated to 700-750°, gave yields of  $\text{HCHO}$  up to 4%; the concn of the  $\text{HCHO}$  soln. recovered was 10-25%. Mixts. of  $\text{C}_6\text{H}_6$  vapor and air under similar conditions gave yields of  $\text{PhOH}$  up to 5% on the  $\text{C}_6\text{H}_6$  taken and up to 50% on that attacked.

T. H. CHILTON

**Catalytic production of benzaldehyde.** P. SHORIGIN, I. KIZBERG AND E. SMOL'YANIKOVA. *Zhur. Prikladnoi Khim.* 2, 149-54 (1929).—See *C. A.* 23, 3680. V. K.

**1,6-Heptadiene and 1,8-nonadiene.** LESPIEAU AND JOURNAUD. *Compt. rend.* 188, 1410-1 (1929).— $\text{CH}_2\text{:CBr(CH}_2\text{)}_3\text{CBr:CH}_2$ , as prepd. from epibromohydrin and the mixed Mg compd. from  $\text{CH}_2\text{:CBrCH}_2\text{CH}_2\text{Br}$ , was mixed with its higher homolog and so difficult to sep. that it yielded 1,6-heptadiene (I) contaminated with the  $\text{C}_8$  compd. The action of  $\text{HC:CNa}$  (theoretical amt. of Na) on  $\text{Br(CH}_2\text{)}_3\text{Br}$  or  $\text{Br(CH}_2\text{)}_5\text{Br}$  at ordinary pressure gave chiefly I or 1,8-nonadiene (II). I b. 111.5-2.5°,  $d_{17}$  0.8164,  $n_D^{17}$  1.451, mol. refraction 30.34 (calcd. 30.52). It pptd.  $\text{NH}_3$  solns. of  $\text{CuCl}$ , aq. solns. of  $\text{HgCl}_2$  and  $\text{NH}_3$  or alc. solns. of  $\text{AgNO}_3$ . The last ppt. corresponded to  $\text{C}_7\text{H}_6\text{Ag}_2$ .  $2\text{AgNO}_3$  and with a soln. of I containing  $\text{I}^-$  formed  $(\text{Cl}_2\text{:Cl})_2(\text{CH}_2)_3$ , m. 75.5-6.5°. II b. 55.0-5° m. —21°,  $d_{21}$  0.8159,  $n_D^{21}$  1.452, mol. refraction 39.69 (calcd. 39.75). The ppt. with  $\text{AgNO}_3$  (analogous to that from I) yielded  $(\text{Cl}_2\text{:Cl})_2(\text{CH}_2)_5$ , m. 107-8°.

JANET D. SCOTT

**Rearrangement of acetylenic carbinols into ethylenic ketones.** ANTOINE WILLE-

MART. *Compt. rend.* 188, 1172-4(1929).—New carbinols,  $R^1R^2C(OH)C:CR^3$  were transformed into ketones,  $R^1R^2C:CHCOR^3$  (1) by heating with EtOH and  $H_2SO_4$  or (2) by conversion into esters,  $R^1R^2CCIC:CR^3$ , followed by heating with EtOH. Other authors have noted rearrangements in which  $R^1$ ,  $R^2$  and  $R^3$  are Ph radicals or their derivs. The expts. recorded below indicate that these rearrangements are general. 1,1-Diphenyl-1-hydroxy-2-octene,  $Ph_2C(OH)C:C(CH_2)_6Me$  (I),  $b_1$  179–80°, gives by method (1) 1,1-diphenyl-3-keto-2-octene,  $Ph_2C:CHCO(CH_2)_6Me$ ,  $m$ . 7–8°,  $b_1$  173°. The HCl ester of I could not be prepd. with  $PCl_5$ . 1,1-Diphenyl-1-hydroxy-3-*p*-tolyl-2-propene,  $Ph_2C(OH)C:CC_6H_4Me$ ,  $m$ . 68–9°, gives by both methods, 1,1-diphenyl-3-keto-3-*p*-tolyl-1-propene,  $Ph_2C:CHCOC_6H_4Me$ ,  $m$ . 74–5°. 1,3-Diphenyl-1-hydroxy-1- $\alpha$ -naphthyl-2-propene,  $Ph(C_{10}H_7)C(OH)C:CPh$ ,  $m$ . 137–8°, could not be transformed directly, but gave an HCl ester which gave 1,3-diphenyl-1-hydroxy-3-keto-1- $\alpha$ -naphthyl-1-propene,  $Ph(C_{10}H_7)C:CHCOPh$ ,  $m$ . 107–8°. 1,1-Di- $\alpha$ -naphthyl-1-hydroxy-3-phenyl-2-propene,  $(C_{10}H_7)_2C(OH)C:CPh$ ,  $m$ . 70–1°, gives by both methods 1,1-di- $\alpha$ -naphthyl-3-keto-3-phenyl-1-propene,  $(C_{10}H_7)_2C:CHCOPh$ ,  $m$ . 170–1°. 1,1-Diphenyl-1-hydroxy-3- $\beta$ -naphthyl-2-propene,  $Ph_2C(OH)C:CC_{10}H_7$ ,  $m$ . 99–100°, gives by both methods 1,1-diphenyl-3-keto-3- $\beta$ -naphthyl-1-propene,  $Ph_2C:CHCOC_{10}H_7$ ,  $m$ . 168–9°.

MARGARET W. MCPHERSON

2-Methyl-2,6-heptenol and natural *d*-citronellol. JEAN DOEUVRE. *Bull. soc. chim.* 45, 351–64(1929).—*Geraniol* (I) (300 g.) and 150 g. of KOH were heated for 8 hrs. at 160° with 200 cc. of 95% EtOH. The product was washed with  $H_2O$ , neutralized with HOAc and fractionated, giving (a),  $b_{14}$  76°, resembling 2-methyl-2,6-heptenone (II), (b),  $b_{14}$  78–9° (60 g.), 2-methyl-2,6-heptenol (III), (c),  $b_{14}$  115–25° (100 g.), I and *d*-citronellol (IV), and (d),  $b_{14}$  over 125° (80 g.), unidentified liquids. III,  $b_{24}$  88–9°,  $b_{760}$  177–8° (cor.),  $d_4^{14}$  0.855,  $n_D^{14}$  1.5411, surface tension  $\gamma_{17}$  27.8 dynes/cm. (*allopphanate*,  $m$  99–100°), contained 10% of 2-methyl-1,6-heptenol, as established by the products of  $O_3$  oxidation, corresponding to 10% of the  $\beta$ -form of I present in the original mixt. III (25 g.) and 280 g. of 25%  $H_2SO_4$  were stirred for 20 hrs.; the product was filtered, satd. with  $(NH_4)_2SO_4$  and extd. with  $Et_2O$ . Distn. gave 2-methyl-2,6-heptanedial,  $b_{14}$  124–6°,  $d_4^{12.4}$  0.946,  $n_D^{12.4}$  1.4569. III (12.8 g.) was treated with 88 g. of const.-boiling III in an ice bath, allowed to stand for 36 hrs., heated at 40° for 30 min. and finally extd. with PhH, decolorized with  $NaHSO_3$  and fractionated, giving 6 g. of 2,2,6-trimethyltetrahydropyran (V),  $b_{760}$  127–8°,  $d_4^{12.6}$  0.853,  $n_D^{12.6}$  1.4285. Had III been 2,6-dimethyl-2,6-heptenol, as stated by Barbier (*Compt. rend.* 126, 1423; 128, 110), the product would have been the 2,2,4,4-tetra-Me deriv.,  $b$ . 141–3° (*allopphanate*  $m$ . 108°), instead of V. It is suggested that II is formed from I through consecutive hydrolysis and loss of EtOH which then condenses, forming the high-boiling fraction (d) and in so doing, reduces a part of the ketone to III. This is substantiated by the conversion of II to III in the same manner as the prepn. of III from I. With  $SOCl_2$ , III gave V and 2-methyl-6-chloro-2-heptene,  $b_{15}$  59–61°. Fifty g. of III in 60 cc. of  $CCl_4$  was treated with 40 g. of  $PBr_3$  in 30 cc. of  $CCl_4$  at 0°; after boiling, washing and neutralizing with 5% NaOH, fractionation gave 60% of 2-methyl-6-bromoheptene,  $b_{14}$  71–2°,  $d_4^{17}$  1.146,  $n_D^{17}$  1.4720, which, from the products of  $O_3$  oxidation, appeared to be 22% of the 1-heptene and 76% of the 2-heptene, indicating isomerization. Boiling III with HI gave a small quantity of V and a mixt.,  $b$ . 95–105°, contg. 2-methyl-6-iodoheptene and 2-methyl-duodoheptene. The recovered mixt. contg. I and IV was treated with KOH until all of the I was removed, giving pure IV,  $b_{20}$  119–21°,  $d_4^{17}$  0.866,  $n_D^{17}$  1.4617,  $[\alpha]_D^{18} + 2^\circ 14'$ .  $O_3$  oxidation proved this pure IV to be approx. 20%  $\alpha$ - and 80% of the  $\beta$ -form. This would constitute the compn. of the naturally occurring mixt. Equal wts. of pure IV and  $BzCl$  were heated at 140–60° for 8 hrs. and the benzoate,  $b$ . 190–200°, was sapond. and fractionated, giving repurified IV,  $b_{18}$  119° (cor.),  $d_4^{16}$  0.860,  $n_D^{16}$  1.4572,  $[\alpha]_D^{16}$   $2^\circ 18'$ , *allopphanate*,  $m$ . 104.5–5.5° (cor.), which was 39% of the  $\alpha$ - and 59% of the  $\beta$ -form, indicating isomerization. This shift of C:C is due to HCl (by hydrolysis of  $BzCl$ ) for treatment of IV with dry HCl heated at 150° gave 42%  $\alpha$ - and 54%  $\beta$ -isomer. This is explained by the addn. of HCl at the double bond and its subsequent removal to give C:C in positions 1 and 2.

The ketosulfonic acids. I. Synthesis of some derivatives of thiodiazole. PAWEŁ MAZÁK AND JERZY SUSZKO. *Roczniki Chem.* 9, 431–43 (443 French)(1929).—A certain analogy between  $\beta$ -ketosulfonic and  $\beta$ -ketocarboxylic acids as is the case between acetonesulfonic (I) and acetoacetic acid can be seen in the 2 following points: (a) I is decompd. under the influence of sirupy  $H_3PO_4$  at moderate temps. and under the influence of concd.  $H_2SO_4$  even in the cold with liberation of  $SO_2$ ; (b) the phenylhydrazone,

$\text{MeC}:(\text{NNHPh})\text{CH}_2\text{SO}_3\text{K}$ , of the K salt of I, is condensed by the action of  $\text{PCl}_3$  into 2,5-dihydro-4-methyl-2-phenyl-1,2,3-thiadiazole 1-dioxide, m.  $84-5^\circ$ , which is distinguished by a remarkable resistance toward acids, whereas under the influence of alkalis it undergoes decompn. quite readily with the formation of the phenylhydrazone of I. It has an acid as well as a basic character. Also the phenomenon of tautomerism has been observed. Properties exhibited by the Br derivs. (5-Br, m.  $123^\circ$ ; 5,5-di-Br, m.  $96^\circ$ ) and the 5-nitro deriv., m.  $170-2^\circ$ , permit of drawing the conclusion regarding the position of substituents on C atom 5 of the thiadiazole nucleus (methylene C). J. K.

**Effect of pressure on the formation of Grignard reagents.** HENRY GILMAN, R. J. VANDER WAL AND F. E. BROWN. *Bull. soc. chim.* **45**, 350-1 (1929).—Observation of a decrease in vol. in the prepn. of some Grignard reagents has led to a study of the effect of pressure upon the reaction. The time of formation of  $\text{BuMgBr}$ , as indicated by the color reaction of Gilman and Schulze (*C. A.* **19**, 2473; **22**, 942), was reduced from 8.6 mins. to 8.1 mins. by the application of 2-3 atms. pressure. The slow reaction between  $\text{PhCl}$  and Mg was not accelerated by heating in a sealed tube at  $100^\circ$  or by a pressure of 96 atms. at room temp. A. S. CARTER

**Relative activity of some organic halides. Relative times of formation of some Grignard reagents.** HENRY GILMAN AND R. J. VANDER WAL. *Bull. soc. chim.* **45**, 344-9 (1929); cf. *C. A.* **23**, 1868.—Applying the color test of Gilman and Schulze (*C. A.* **19**, 2473; **22**, 942), 5 cc. of  $\text{Et}_2\text{O}$ , 0.0187 mol. of halide and 0.5 g. of Mg turnings were mixed and portions removed at regular time intervals for test. The following data with regard to the av. time necessary for color development relative to structure were obtained. The order of increasing activity of the halides was F, Cl, Br and I, though the formation of  $\text{R}-\text{R.MgI}_2$  was favored in the case of iodides and the color reaction, which depended upon the formation of  $\text{RMgX}$ , sometimes appeared as rapidly with bromides. A regular decrease in rate resulted with an increase in the no. of C atoms; the following times are in mins.:  $\text{PrBr}$  6.5,  $\text{BuBr}$  7.5,  $\text{C}_7\text{H}_{15}\text{Br}$  12.5,  $\text{C}_8\text{H}_{17}\text{Br}$  16.3,  $\text{MeI}$  3.5,  $\text{EtI}$  4.5,  $\text{PrI}$  6.4,  $\text{BuI}$  7.6,  $\text{C}_6\text{H}_{13}\text{I}$  27.5,  $\text{BuCl}$  no reaction,  $\text{PhI}$  11,  $\text{PhBr}$  20. Owing to the catalytic effect of free  $\text{I}_2$  alkyl iodides which had not been treated with  $\text{Hg}$  during their prepn. reacted more readily than those which had. Complex chains showed greater activity than their normal isomers:  $\text{BuBr}$  7.5, *iso*- $\text{BuBr}$  5.4, *sec*- $\text{BuBr}$  3.5; it was found impossible to test *tert*- $\text{BuBr}$  for the product was  $\text{Bu}-\text{Bu.MgBr}_2$  and not the color-forming  $\text{BuMgBr}$ . The following bromotoluenes indicated the effect of position in the  $\text{PhH}$  ring (with 10 drops of a 5% soln. of  $\text{I}_2$  in  $\text{Et}_2\text{O}$  as catalyst: *p*- $\text{BrC}_6\text{H}_4\text{Me}$  16.5, *m*- $\text{BrC}_6\text{H}_4\text{Me}$  20.5, *o*- $\text{BrC}_6\text{H}_4\text{Me}$  23;  $\beta$ -bromonaphthalene was much more rapid than the  $\alpha$ -compd. when tested without a catalyst; with the catalyst, the times were  $\alpha$  25.8,  $\beta$  21.2. The following were also tested:  $\text{PhCH}_2\text{Cl}$  25 mins., bromocyclohexane 25, chlorocyclohexane no reaction,  $\text{PhCH}_2\text{CHBr}$  no reaction,  $\text{p-C}_6\text{H}_4\text{Br}_2$  no reaction without a catalyst, but with the catalyst, the time was 15 min. A. S. C.

**Further investigations on the color reactions of metallo-organic compounds.** HENRY GILMAN AND LLOYD I. HECK. *Ber.* **62B**, 1379-84 (1929).—See *C. A.* **23**, 1869.

HANS J. DUBS

**Derivatives of hexamethylenetetramine with phenols, phenol derivatives and sugars.** J. E. LABORDE. *Chimie & industrie Special No.*, 504-10 (Feb., 1929).—Hexamethylenetetramine *o*-phenolsulfonate, from 30% aq.  $\text{o-HOC}_6\text{H}_4\text{SO}_3\text{H}$  with aq. hexamethylenetetramine (I) in equimol. proportions evapd. *in vacuo* over  $\text{H}_2\text{SO}_4$ , m.  $140^\circ$ , b.  $180^\circ$ ,  $n_D^{20}$  (0.023 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3357, decompd. by boiling water with liberation of  $\text{PhOH}$ , by hot mineral acids with liberation of  $\text{PhOH}$  and  $\text{CH}_2\text{O}$  and by hot alkalis with liberation of  $\text{NH}_3$ ; the crystals in hot  $\text{H}_2\text{O}$  give a red color with Millon's reagent, and a brick-red ppt. on cooling; a hot aq. soln. gives a yellowish white ppt. with Br water or with nascent Br. *Di-I o-phenolsulfonate*, prepd. as above, but with 2 mol. of I, m.  $160^\circ$ ,  $n_D^{20}$  (0.023 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3369, gives the same reactions with hot  $\text{H}_2\text{O}$ , acids and alkalis, a reddish brown color with  $\text{FeCl}_3$  and a pinkish white ppt. with Millon's reagent. I *p-phenolsulfonate*, from 1 mol. of  $\text{p-HOC}_6\text{H}_4\text{SO}_3\text{H}$  in 30 cc. of 95% alc. and 1 mol. of I in 30 cc. of 45% alc., evapd. in the air at room temp., m.  $180-2^\circ$ ,  $n_D^{20}$  (0.023 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3369, decompd. as above by hot acids and alkalis, gives a violet-brown color with  $\text{FeCl}_3$ , a pink color with Millon's reagent and a pink ppt. on cooling. *Di-I p-phenolsulfonate*, from 2 mol. of I per mol. of  $\text{p-HOC}_6\text{H}_4\text{SO}_3\text{H}$ , m. about  $190^\circ$  with conversion into a brown resinous mass,  $n_D^{20}$  (0.023 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3978, not decompd. by alkalis, decompd. by acids with liberation of  $\text{PhOH}$  in the cold and of  $\text{PhOH}$  and  $\text{CH}_2\text{O}$  at higher temp., gives a greenish brown color with  $\text{FeCl}_3$ , and a yellow ppt. with Millon's reagent when hot. Hexamethylenetetramine thymolate, from 1 mol. of thymol and 2 mol. of I, in  $\text{CHCl}_3$ , begins melting at  $40^\circ$  but is not com-

pletely melted until  $180^{\circ}$ ,  $n_D^{20}$  (0.023 g. in 1 g. abs. alc.) 1.3658, decompd. by strong acids with liberation of thymol and  $\text{CH}_2\text{O}$ , not decompd. by alkalis either hot or cold. *I thymolsulfonate*, from equimol. amts. of thymolsulfonic acid in 95% alc. and **I** in 40% alc., decomp.  $250^{\circ}$  with evolution of vapors having a pyridine-like odor; in spite of repeated crystallizations, it could not be obtained pure and well crystallized. *Di-I thymolsulfonate*, from 1 mol. thymolsulfonic acid and 2 mols. of **I** in alc. solns.,  $n_D^{20}$  (0.023 g. in 1 g. abs. alc.) 1.3638, decompd. by hot mineral acids with liberation of thymol and  $\text{CH}_2\text{O}$ , unaffected by hot alkalis. No crystalline products could be obtained with glucose, fructose or maltose. Cryst. derivs. were obtained by mixing equimol. amts. of sugar and **I** in 40% alc. (sucrose, galactose) or  $\text{H}_2\text{O}$  (lactose), evapd. to a sirupy consistency at  $40^{\circ}$  and then in vacuum over  $\text{H}_2\text{SO}_4$  for 2 weeks (3 days in the case of galactose). The *sucrose deriv.* is odorless, sweet, m.  $160^{\circ}$ ,  $n_D^{20}$  (0.020 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3348,  $\alpha_D^{15}$  (5% soln.)  $8.10^{\circ}$ , unaffected by hot alkalis, decompd. by mineral acids with liberation of  $\text{CH}_2\text{O}$ ; the sugar portion of the mol. gives the usual reactions for sucrose. The *lactose deriv.* is odorless, less sweet than the sucrose deriv., m.  $180^{\circ}$ ,  $\alpha_D^{15}$  (5%)  $7.40^{\circ}$ ,  $n_D^{20}$  (0.022 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3348. The *galactose deriv.* is odorless, sweet, m.  $180^{\circ}$ ,  $n_D^{20}$  (0.020 g. in 1 cc.  $\text{H}_2\text{O}$ ) 1.3355,  $\alpha_D^{15}$  (5% soln.)  $7.40^{\circ}$ , decompd. by hot alkalis with evolution of  $\text{NH}_3$  by mineral acids with evolution of  $\text{CH}_2\text{O}$ .

A. PAPINEAU-COUTURE

**Dipole moments, association and ultra-violet absorption of aliphatic ketones and their solutions. I. Solvent influence and reaction mechanism from the standpoint of the dipole theory.** K. L. WOLF. *Z. physik. Chem.*, Abt. B, 2, 39-76 (1929).—The dipole moment of saturated aliphatic ketones is independent of the length of the C chain and is equal to  $2.74 \times 10^{-18}$ . The solvent displacement of the absorption bands is dependent on the polar groups. There is a direct relation between this displacement and the amount of association of the ketone soln. Both of these phenomena, as well as the case of formation of the bisulfite and oxime compounds, are dependent on the size of the dipole moment and the hindrance of polar groups by indifferent (electro-sym.)  $\text{CH}_2$  groups. The 10 ketones studied belong to the acetone homologous series. The solvents used included hexane, EtOH, MeOH,  $\text{H}_2\text{O}$  and benzene.

WALLACE R. BRODE

**Diazomethane methylations in the presence of catalysts. II.** HANS MEERWEIN, THEODOR BERSIN AND WILLY BURNELEIT. *Ber.* 62B, 999-1009 (1929); cf. C. A. 23, 97. It was reported in the 1st paper that ketones, which, with few exceptions, do not react with  $\text{CH}_2\text{N}_2$ , can be made to react smoothly in the presence of suitable catalysts, with formation of ethylene oxides and homologous ketones. In view of a recent statement by Arndt (C. A. 23, 2441), the behavior of  $\text{Me}_2\text{CO}$  toward  $\text{CH}_2\text{N}_2$  in the absence of catalysts has again been studied (with PAUL PÖHL) and it has been found, as before, that neither undil.  $\text{Me}_2\text{CO}$  nor its solns. in Et<sub>2</sub>O, PhMe, heptane, MeCN,  $\text{CHCl}_3$  or  $\text{Ac}_2\text{O}$  react to any appreciable extent with  $\text{CH}_2\text{N}_2$ . Not only was the velocity of  $\text{N}_2$  evolution followed but at the same time the decrease in the  $\text{CH}_2\text{N}_2$  content of the solns. was detd. in the usual way by titration with BzOH in Et<sub>2</sub>O; in every case the decrease was exceedingly small and can be ascribed to the spontaneous decomposition of the  $\text{CH}_2\text{N}_2$ . Contrary to Arndt, no addn. product of  $\text{CH}_2\text{N}_2$  to  $\text{Me}_2\text{CO}$  was observed. That such addn. products are not decompd. by BzOH in Et<sub>2</sub>O, i. e., that free  $\text{CH}_2\text{N}_2$  can be detd. in this way in their presence, was shown by control expts. with Schlotterbeck's  $\text{CH}_2\text{N}_2\text{-CCl}_3\text{CHO}$  addn. product. Nevertheless, the reaction between  $\text{CH}_2\text{N}_2$  and ketones is quite sensitive toward catalysts and the small decomposition velocities reported in this paper can be obtained only by careful work. As already pointed out, the substances acting as catalysts are in the 1st place electrolytes, i. e., pronouncedly heteropolar substances like acids and salts, and, secondly, compounds with a strong dipolar character, such as  $\text{H}_2\text{O}$  and the alics. To the latter class has now been added another representative, viz.,  $\text{HCONH}_2$ . Its effectiveness is not quite as great as that of  $\text{H}_2\text{O}$ , so it can hardly find practical application; however,  $\text{Me}_2\text{CO}$  with 70% of its wt. of  $\text{HCONH}_2$  reacts quite vigorously with  $\text{CH}_2\text{N}_2$ , giving chiefly *asym*-dimethylene oxide with some  $\text{MeCOEt}$  and probably higher ketones; the  $\text{HCONH}_2$  itself is methylated only in traces at most. This accelerating action of  $\text{HCONH}_2$  supports the view that it is the polar character of these substances which is the decisive factor in detg. their catalytic influence, i. e., that their action depends on the formation of complexes with a greater dipolar moment and which, because of the greater electrostatic forces radiating from them, have a greater additive power toward  $\text{CH}_2\text{N}_2$ . A no. of investigators consider that the hydrates and alcoholates of aldehydes are not normal valence compounds, but complexes,  $\text{RCHO} \cdots \text{HOH}$ . This seemed to be supported by the observation of Arndt and Eistert that  $\text{CCl}_3\text{CHO} \cdot \text{H}_2\text{O}$  and  $\text{CH}_2\text{N}_2$  in Et<sub>2</sub>O give chiefly 3,3,3-trichloropropylene 1,2-oxide (**I**), i. e., the methylation product of free  $\text{CCl}_3\text{CHO}$ . The  $\text{CCl}_3\text{-}$

$\text{CHO} \cdot \text{H}_2\text{O}$  reacts at once with vigorous evolution of  $\text{N}_2$ , whereas free  $\text{CCl}_3\text{CHO}$ , as found by Schlotterbeck, first forms with the  $\text{CH}_2\text{N}_2$  an addn. compd. which evolves  $\text{N}_2$  only when the  $\text{Et}_2\text{O}$  is evapd. off. To clear up this point the action of  $\text{CH}_2\text{N}_2$  on  $\text{CCl}_3\text{CH}(\text{O}) \cdot \text{H}_2\text{O}$  and a series of chloral alcoholates in the corresponding alcs. has been thoroughly studied. From the hydrate in  $\text{Et}_2\text{O}$  were obtained, along with I as the chief product,  $\text{CCl}_3\text{CH}(\text{OMe})_2$  (II),  $\text{MeOH}$ ,  $\text{Me}_2\text{O}$  and a high-boiling N-contg. product (b. 98–103°) which has not been identified. The formation of II can be explained only by the assumption that the hydrate is a normal valence compd.,  $\text{CCl}_3\text{CH}(\text{OH})_2$ , and that the methylation of its OH groups is due to its acidity. Since mol. wt. detns. indicate that the hydrate in solns. at 0° is only very slightly dissociated into its components, the formation of I as the chief product would seem to indicate that the free  $\text{CCl}_3\text{CHO}$ , at least in  $\text{Et}_2\text{O}$ , reacts with  $\text{CH}_2\text{N}_2$  with extraordinarily greater velocity than does the hydrate, the reaction probably being accelerated by the acidic character of the hydrate. To this acid character of the hydrate is also ascribed the fact that the primary  $\text{CH}_2\text{N}_2$ - $\text{CCl}_3\text{CHO}$  addn. product at once evolves  $\text{N}_2$  in the presence of the hydrate. The formation of  $\text{MeOH}$  and  $\text{Me}_2\text{O}$  can also readily be explained as resulting from the methylation of  $\text{H}_2\text{O}$  and  $\text{MeOH}$  under the catalytic influence of the hydrate. With the chloral alcoholates in the corresponding alcs. the reaction is quite analogous. Along with I are formed the unsym. acetals,  $\text{CCl}_3\text{CH}(\text{OR})\text{OMe}$ , and more or less of the Me ethers of the alcs. The relative proportions of I and acetals formed depend greatly on the nature of the alc.; 10.9, 9.6, 23.4, 16.6 and 88.8% of I were obtained in Et, Pr, iso-Pr, Bu and *tert*-Bu alc., resp. In the presence of 25% of its wt. of the weakly acidic  $\text{CCl}_3\text{CH}_2\text{OH}$  (III)  $\text{Me}_2\text{CO}$  reacts extraordinarily vigorously with  $\text{CH}_2\text{N}_2$  and practically only the  $\text{Me}_2\text{CO}$  is methylated, with formation of *asym*-dimethylethylene oxide and  $\text{MeCOEt}$ . The fact that the III itself is not methylated whereas org. acid catalysts ( $\text{BzOH}$  ( $\text{CO}_2\text{H}$ )<sub>2</sub>), react appreciably with the  $\text{CH}_2\text{N}_2$ , would seem to indicate that it is not only the strength of the acid but also the nature of the anion which detts. the ease with which an acid is methylated by  $\text{CH}_2\text{N}_2$ . C. A. R.

**New method for the preparation of pentadecylic acid.** STANISLAS LANDA. *Chimie & industrie Special No.*, 524 (Feb., 1929); cf. C. A. 23, 1872.—In a large flask gradually add hot 1%  $\text{KMnO}_4$  soln. to hot cetene (about 2 parts  $\text{KMnO}_4$  to 1 part cetene); when oxidation is complete let cool, pass  $\text{SO}_2$  till the liquid is clear and the bulky acid collects at the surface of the liquid. To purify the crude acid, dissolve in 3 parts of abs. alc., satd. with  $\text{HCl}$  gas, decant the soln., wash the ester with hot water till free from acid, dehydrate, distil in vacuum (the Et pentadecylate b.<sub>16</sub> 172–4°), sapon. the distillate, acidify, and recrystallize once from petroleic ether (d. 0.718) refined with fuming  $\text{H}_2\text{SO}_4$  (preferable to 70% alc. owing to the ease with which the acid is esterified). The pure acid b.<sub>13</sub> 193–5°, m. 52–52.5°.

**Action of ethylmagnesium bromide on tetraethylsuccinamide.** HUAN. *Compt. rend.* 188, 1174–6 (1929); cf. Blaise and Montague, C. A. 19, 2476; Barré, C. A. 22, 579.— $\text{EtMgBr}$  and  $(\text{CH}_3\text{CONEt}_2)_2$  give 3% of  $(\text{CH}_3\text{COEt})_2$  (I) and 63% of  $\beta$ -propiolyl diethylpropionamide,  $\text{EtCO}(\text{CH}_2)_2\text{CONEt}_2$  (II), b.<sub>12</sub> 142–3°; semicarbazone, m. 138°; phenylhydrazone, m. 107°; *p*-nitrophenylhydrazone, m. 165°. II and 48%  $\text{HBr}$  boiled several hrs. give  $\text{EtCO}(\text{CH}_2)_2\text{CO}_2\text{H}$ . II and excess  $\text{EtMgBr}$  give principally  $\gamma$ -hydroxy- $\gamma$ -ethylcaproic diethylamide,  $\text{Et}_2\text{C}(\text{OH})(\text{CH}_2)_2\text{CONEt}_2$  (III), b.<sub>13</sub> 166–8°, 5% of I, and a  $\gamma$ -ketol, which loses  $\text{H}_2\text{O}$  to become  $\alpha$ -ethyl- $\alpha'$ -diethylidihydrofurfuran (IV), b.<sub>11</sub> 55–6°. IV and semicarbazide in aq.  $\text{EtOH}$  give the semicarbazone of the corresponding  $\gamma$ -ketol, m. 95°. III and  $\text{Ac}_2\text{O}$  give  $\text{AcNEt}_2$ , b. 185°, and  $\gamma$ -diethylbutyrolactone,  $\text{Et}_2\text{C}(\text{CH}_2)_2\text{CO}_2\text{O}$ , b.<sub>10</sub> 107–9°, which gives with  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$  a compd. m. 78°.  $\text{EtO}-$

$\text{CO}(\text{CH}_2)_2\text{CONEt}_2$  and  $\text{EtMgBr}$  give slightly different yields of the same substances

MARGARET W. MCPHERSON  
**The preparation of pure oleic acid.** E. RAYMOND. *Chimie & industrie Special No.*, 523 (Feb., 1929); cf. Bertram, C. A. 21, 2662.—Bertram's method is complicated and expensive, because of the use of  $\text{Hg}(\text{OAc})_2$ , and moreover it leaves 0.5% of satd. acids, which is no better than Twitchell's method. Better results were obtained by the following method, which is similar to Bertram's but simpler and cheaper: sep. the greater portion of the satd. acids by pressing the fatty acids of almond or olive oil at low temp. (10–12°), dissolve the sepd. unsatd. acids in 4 vols. of alc. contg. 1.5 times the  $\text{Pb}(\text{OAc})_2$  theoretically required to ppt. the satd. acids present, purify the crude oleic acid by recrystn. at  $-15^\circ$  to  $-25^\circ$  from its 50% soln. in alc., which easily removes other unsatd. acids and any traces of satd. acids which remained in the crude acid. Crystn. at low temp. is readily carried out in a tube provided with a perforated piston over which is a filter cloth; the tube is immersed in the  $\text{CaCl}_2$  bath of a refrigerating

machine, and after the oleic acid has crystd. the piston is lowered to the bottom of the tube, the underlying crystals being completely free from mother liquor. After 3 crystns. pure oleic acid is obtained, solidifying at 13°, and giving an isomeric form, m. 16°.

A. PAPINEAU-COUTURE

**A relation between boiling point and molecular architecture of *cis-trans*-ethylenic acids, saturated acids and acetylenic acids.** M. BOURGUEL. *Compt. rend.* 188, 1494-6 (1929).—A study of a certain no. of straight-chain  $\alpha$ -ethylenic acids, *i. e.*, higher homologs of crotonic and isocrotonic acids, has shown a clear relationship in the phys. consts. of the *cis*- and *trans*-series. The ethylenic acids, 1-heptene- and 1-octenecarboxylic acids, were obtained from 1-heptene- and 1-octenecarboxylic acids, resp., by hydrogenation with colloidal Pt (C. A. 20, 2977). Thus obtained, they were considered as *cis*-isomers; treatment with I converts them to the *trans*-isomers. For *cis*-isomers with 4, 5, 6, 8 and 9 C atoms the b. ps. at 15 mm. are 73°, 88°, 101°, 127° and 140°, resp. For *trans*-isomers with 4, 5, 8 and 9 C atoms, the b. ps. at 15 mm. are 93°, 106°, 143° and 154.5°, resp. For both series there is a uniform gradation which may be expressed as a linear function. The b. ps. of the corresponding satd. acids coincide closely with those of the *cis*-ethylenic isomers and the b. ps. of the corresponding acetylenic series coincide closely with those of the *trans*-ethylenic series. D. and  $n_D$  of the *cis*-isomers are consistently lower than those of the *trans*-isomers.

R. P. WALTON

**Action of organo-magnesium derivatives on the ethyl ester of ethylcyanoacetate.** A. MAVRODIN. *Compt. rend.* 188, 1504-6 (1929).—When Et ethylcyanoacetate (I) is treated with organo-Mg halides in boiling ether, the only reaction is the decompn. of 1 mol. of the organo-Mg halide by the enolic HO, with liberation of the hydrocarbon; on hydrolysis I is recovered almost quantitatively. The CN grouping, which in NC-CH<sub>2</sub>-CO<sub>2</sub>Et is attacked in the cold by the Mg halide, is much more resistant in I. The 2 groupings of I are brought into play if it is heated in boiling toluene for several hrs. But while the CN grouping is converted smoothly into the ketone, the ester grouping is not converted to the tertiary alc. as might be expected but stops at the ketonic stage, the resulting product being a sym.  $\alpha$ -alkyl- $\beta$ -diketone, RCOCH<sub>2</sub>EtCOR. By such procedure EtMgI gives ethyldipropionylmethane (II), b<sub>10</sub> 91-2°, in 25-30% yield. II is characterized by the deriv. which it gives with semicarbazide in the cold, *i. e.*, the 3,4,5-triethylpyrazole-1-carboxamide, m. 98°. By the same procedure PhMgBr gives ethyldibenzoylmethane (III) in 60% yield. This substance combines directly with semicarbazide, giving 4-ethyl-3,5-diphenylpyrazole (IV), m. 167°. The picrate of IV m. 161°. Treatment of III with NH<sub>2</sub>OH gives 3-ethyl-2,4-diphenylisoxazole, m. 93-4°. The action of organo-Mg derivs. on the Et alkylcyanoacetates, accordingly, constitutes a practical procedure for obtaining sym. alkyl- $\beta$ -diketones which are difficult to prep. by other means.

R. P. WALTON

**Preparation of acetic anhydride.** E. FRITZMAN. *Zhur. Prikladnoi Khim.* 1, 27-36 (1928).—Introduce 985 g. powd. AcONa and 48 g. S in a 3 l. flask and add 1200 g. of Ac<sub>2</sub>O (CCl<sub>4</sub>, CHCl<sub>3</sub>, C<sub>6</sub>H<sub>6</sub>, PhMe or similar substances might be used). Pass 320 g. Cl<sub>2</sub> for 1 hr. 15 min. while the mixt. is agitated and the flask cooled with water and then keep the mixt. at 90° for 1 hr. more. Distil off Ac<sub>2</sub>O at 100° and 50-100 mm. Hg. The yield is about 90%. On a larger scale cast iron and steel app. can be used, but Pb and Sn are quickly corroded. Al is not affected by Ac<sub>2</sub>O even after 3 hrs. boiling. Another method of prep. Ac<sub>2</sub>O which is commercially promising consists in mixing equimol quantities of anhyd. AcONa and *p*-MeC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>Cl, the by-product in mfg. saccharin, and distg. the Ac<sub>2</sub>O produced at 170-200°. The yield is 80-90%. V. K.

**Esterification velocity of fatty acids with ethylene glycol-hydrochloric acid.** ANTON KAILAN and ADOLFINE SCHACHNER. *Monatsh.* 52, 23-52 (1929).—Results are reported for C<sub>17</sub>H<sub>35</sub>CO<sub>2</sub>H (I), C<sub>18</sub>H<sub>37</sub>CO<sub>2</sub>H (II), C<sub>19</sub>H<sub>39</sub>CO<sub>2</sub>H (III), iso-C<sub>17</sub>H<sub>33</sub>CO<sub>2</sub>H (IV) and iso-C<sub>18</sub>H<sub>35</sub>CO<sub>2</sub>H (V) in 107 tables. The monomol. velocity consts. for the esterification of I, II and III in C<sub>2</sub>H<sub>4</sub>(OH)<sub>2</sub> catalyzed by HCl show, within the limits of error, the same values as for PrCO<sub>2</sub>H and may be expressed by the same formulas as functions of the H<sub>2</sub>O and HCl concns. The const. for V is about 22.4%, of IV about 70% of that for PrCO<sub>2</sub>H. With all acids these are proportional to this in the case of anhyd. glycol or glycol contg. a little H<sub>2</sub>O, but in glycol contg. much H<sub>2</sub>O this is true only up to about 1/4 N HCl concn; with higher HCl concns. this increases more rapidly in glycol contg. much H<sub>2</sub>O. In agreement with earlier measurements, the retarding action of the H<sub>2</sub>O in the glycol is about the same as with C<sub>2</sub>H<sub>5</sub>(OH)<sub>2</sub> and much less than with EtOH. With 0.03-0.06 mols. H<sub>2</sub>O per 1. the velocity const. in EtOH is about 30-40% greater than in glycol, but in glycol it is about 2.5 times as great as in C<sub>2</sub>H<sub>5</sub>(OH)<sub>2</sub>. Under all the exptl. conditions practically complete esterification occurred. The original should be consulted for the mass of exptl. details.

C. J. WEST

**Derivatives of volemitol.** V. ETTÉL. *Collection Czechoslov. Chem. Comm.* **1**, 288-93 (1929); cf. *Ber.* **28**, 1973; *C. A.* **11**, 2462; **14**, 3647; **22**, 4512.—This work concerns the reported identity of volemitol and  $\alpha$ -sedoheptitol. The properties of volemitol are: m. 153-4°,  $[\alpha]_D^{20}$  2.07° for a 3% soln. and 2.08 for a 10% soln.,  $[\alpha]_D$  20.71° for 0.7955 g. of I and 2 g. of borax in 27.6 cc. water. The consts. for some derivs. are: trimethylacetal, m. 212-3°,  $[\alpha]_D$  -13.84° for a 1%  $\text{CHCl}_3$  soln.; triacetylacetal, m. 161-2°,  $[\alpha]_D$  -72.35° for 1%  $\text{CHCl}_3$  soln.; tribenzoylacetal, m. 200° from alc., 214-5° from toluene,  $[\alpha]_D^{20}$  -1.7°; heptacetate, m. 120-1°,  $[\alpha]_D^{20}$  20.7°; heptaphenylcarbamate, m. 266°, insol. in the usual solvents. Comparison with the references above will show that the identity is doubtful.

V. F. HARRINGTON

**The action of peracids on unsaturated compounds and of benzoyl peroxide on a mixture of paraffin hydrocarbons.** J. BÖESEKEN, W. C. SMIT AND GASTER. *Proc. Acad. Sci. Amsterdam* **32**, 377-83 (1929).—The oxidation of Me 9,12-linoleate (I) by  $\text{BzO}_2\text{H}$  or  $\text{AcO}_2\text{H}$  gave 40% Me dioxidostearate (II), m. 31°. Sapon. of II gave a di-oxidostearic acid, m. 79°. Hydrolysis of the ethylene oxide linkages with dil.  $\text{H}_2\text{SO}_4$  at 80° or with 80%  $\text{H}_2\text{SO}_4$  at 0° gives tetrahydroxystearic acids, m. 95° and 148°, resp. The constitution of 9,11-linoleic acid (III), M. R. 77° 88.9, was detd. by ozonization, the products being azelaic and heptanoic acids. Oxidation of the Me ester of III with  $\text{BzO}_2\text{H}$  in  $\text{CHCl}_3$  gives a Me dioxidostearate, m. 47°, which, when sapond., gives 2 di-oxidostearic acids, m. 89° and 75°.  $\text{BzO}_2\text{H}$  and Me oxidoricinelaide in  $\text{CHCl}_3$  give a mixt. of esters which when sapond. at low temp. give 2 oxidocelaic acids, m. 64° and 59°,  $[\alpha]_D^{17}$  -17.2° and 3.4°, resp. Often the oxidation is followed with hydrolysis, forming 2 trihydroxystearic acids, m. 137° and 112°. The consts. for the velocity of oxidation of oleic, elaidic, ricinoleic and ricinelaic acids by  $\text{AcO}_2\text{H}$  at 18° were 0.036, 0.023, 0.026, 0.016, resp.  $\text{AcO}_2\text{H}$  oxidizes triple bonds much more slowly than double bonds. A no. of org. compds. react with  $\text{Bz}_2\text{O}_2$  without a catalyst at 60-100°, giving the

general reaction  $\text{Bz}_2\text{O}_2 + \text{RH} \begin{cases} \rightarrow \text{CO}_2 + \text{BzOR} + \text{PhH} \\ \rightarrow \text{CO}_2 + \text{BzOH} + \text{PhR} \end{cases}$  (RH = aliphatic hydro-

carbon,  $\text{C}_2\text{H}_5\text{Cl}$ , or cyclohexane).  $\text{Bz}_2\text{O}_2$  and petroleum ether (b. 100-2°) give a heptyl benzoate which on hydrolysis gives a tertiary heptyl alc. This is a new method of synthesizing directly tertiary alcs. starting with paraffins, and it shows that  $\text{Bz}_2\text{O}_2$  is selective. The reaction with normal paraffins even at higher temps. is very slow.

FREDERICK C. HAHN

**The configurational relationship of lactic acid and 2-chloropropionic acid with a further note on the configurational relationship of lactic acid and methylpropylcarbinol.** P. A. LEVENE AND H. L. HALLER. *J. Biol. Chem.* **81**, 703-9 (1929), cf. *C. A.* **21**, 3599; **23**, 100, 1876.—The configurations of lactic and chloropropionic acids have been further correlated by the conversion of *d*- $\Delta^2$ -4-pentenol into 1,4-chloropentene and the latter into *d*-2-chloropropionic acid on the one hand and *l*- $\Delta^2$ -4-pentenol into lactic acid on the other. The method gives a direct way of correlating the configurations of all  $\alpha$ -halo acids to one reference substance, namely, to the halopropionic acid. The configurations of *d*-methylpropylcarbinol and *d*-lactic acid have been correlated by a 2nd method, the conversion of *l*- $\Delta^2$ -4-pentenol into both these substances.

A. P. LOTHROP

**Comparative studies on the influence of the substituent in the amino group of polypeptides on their cleavage by normal alkali, erepsin and trypsin-kinase.** EMIL ABDERHALDEN, L. DINERSTEIN AND S. GENES. *Fermentforschung* **10**, 532-43 (1929).—New derivs. described are *p*-chlorobenzoyl-*dl*-leucylglycylglycine (I), m. 183°, obtained by shaking the tripeptide in NaOH with alternate addns. of *p*- $\text{ClC}_6\text{H}_4\text{COCl}$  and 2 *N* NaOH; *p*-nitrobenzoyl-*dl*-leucylglycylglycine (II), m. 163-5°, in the same manner, with a  $\text{C}_6\text{H}_5$  soln. of *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{COCl}$ ; *p*-chlorobenzoyl-*dl*-alanylglycylglycine (III), m. 246-7°; *p*-nitrobenzoyl-*dl*-alanylglycylglycine (IV), decomp. 228-9°;  $\beta$ -naphthalenesulfonyl-*dl*-alanylglycylglycine (V), not crystd., from the tripeptide in NaOH and  $\beta$ - $\text{C}_{10}\text{H}_7\text{SO}_2\text{Cl}$  in  $\text{Et}_2\text{O}$ . Other derivs. included in these tests, but previously described, are *dl*- $\alpha$ -bromoisocaprolyl-*dl*-leucylglycylglycine (VI), *dl*-leucylglycylglycine (VII), *dl*- $\alpha$ -bromoisocaprolyl-*dl*-leucylglycylglycine (VIII), PhNCO deriv. of *dl*-leucylglycylglycine (IX),  $\beta$ -naphthalenesulfonyl-*dl*-leucylglycylglycine (X), *dl*- $\alpha$ -bromopropionylglycylglycine (XI), *dl*-alanylglycylglycine (XII). No polypeptide contg. a substituent in the  $\text{NH}_2$  group was attacked by erepsin at 37° and  $p_{\text{H}}$  7.8. Trypsin-kinase at 37° and  $p_{\text{H}}$  8.4 hydrolyzed I, II, III, IV, VI, VIII, IX and X, but not the 2 peptides VII and XII, nor the derivs. V and XI. *N* NaOH at 37° hydrolyzed VIII and XI the most rapidly. X was hydrolyzed more rapidly than its free tripeptide, but only at the outset. The other derivs.

of VII, viz., I, II, VIII, IX and X, were hydrolyzed somewhat more rapidly than VII, but the difference was not great. Hydrolysis of the tripeptide XII was compared with that of its  $p\text{-ClC}_6\text{H}_4\text{CO}$ ,  $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}$  and  $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$  derivs. Of these, the  $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}$  deriv. was hydrolyzed the most rapidly, and the  $\beta\text{-C}_{10}\text{H}_7\text{SO}_2$  deriv. the most slowly.

A. W. DOX

**The effect of ionization upon optical rotation. IV. Further studies on amino acids and peptides.** P. A. LEVENE, LAWRENCE W. BASS, ALEXANDER ROTWEN AND ROBERT E. STEIGER. *J. Biol. Chem.* **81**, 687–95 (1929); cf. *C. A.* **21**, 3892.—Additional expts. are presented in corroboration of earlier conclusions that the change in rotation on passing from an unionized mol. to the mono-ion, or from the mono-ion to the di-ion, is a linear function of the degree of dissoen. and that this phenomenon can be used to det. dissoen. const. lying in ranges in which electrometric titration does not give accurate results. Data are given for *l*-leucine, *l*-valine, glycyl-*l*-valine, glycyl-*d*-valine and glycyl-*d*-isovaline.

A. P. LOTHROP

**Aromatic levulic amides.** R. LUKEŠ AND V. PRELOG. *Collection Czechoslov. Chem. Comm.* **1**, 282–7 (1929).—Wolff (*Ann.* **299**, 260) by the action of  $\text{NH}_3$  on 2-methyl-5-keto-4,5-dihydrofuran (I) obtained a product to which he assigned an open-chain structure. This has been doubted by Beilstein (4th ed. **3**, 676). L. and P. have prepd. the anilide (II), m. 101–2°, the *p*-toluidide, m. 108–9°, the  $\alpha$ - (m. 105–8°) and the  $\beta$ -naphthalamide of I both by the action of the proper amine on I or  $\gamma$ -acetoxy- $\gamma$ -valerolactone 1-Phenyl-2-methyl-2-hydroxy-5-ketotetrahydropyrrole (III), m. 101°, has been prepd. by the Grignard reaction. A secondary product of this reaction is 1-phenyl-2,5-dimethylpyrrole. II reacts with another mol. of  $\text{PhNH}_2$  to give the anilide of II, m. 145°. III does not. The 2 possible formulas for II are  $\text{MeCOCH}_2\text{CH}_2\text{CONH-}$

$\text{Ph}$  or  $\text{O.CO.CH}_2\text{CH}_2\text{CMeNHPh}$ . The work is to be continued. V. F. HARRINGTON

**Derivatives of cyanomalononic acid.** FRANZ PABST. *Arch. Pharm.* **267**, 325–52 (1929) — After reviewing the studies of Frerichs, Michael and Cobb, and others on this subject, P. describes and characterizes the following derivs.: cyanomalononic Me ester amide,  $\text{NCC}(\text{CONH}_2)\text{CO}_2\text{Me}$ , by heating  $\text{NCCCH}_2\text{CO}_2\text{Me}$  and  $\text{KCNO}$ , m. 116–7°, identical with the product obtained by Frerichs and Hartwig on melting  $\text{NCCCH}_2\text{CO}_2\text{Me}$  with  $\text{KCN}$ , more readily sol. in cold  $\text{H}_2\text{O}$  than the corresponding Et ester; it is acidic, decomg. carbonates and attacking Zn, likewise titratable with phenolphthalein as indicator.  $\text{NCC}(\text{CONHPh})\text{CO}_2\text{Et}$  forms a Ag salt,  $\text{C}_{12}\text{H}_{11}\text{N}_2\text{O}_5\text{Ag}$ .  $\text{NCC}(\text{CONH}_2)\text{CO}_2\text{Et}$  yields with  $\text{KOH}$  and  $\text{PhCH}_2\text{Cl}$  benzylcyanomalononic Et ester amide,  $\text{NCC}(\text{CONH}_2)(\text{CH}_2\text{Ph})\text{CO}_2\text{Et}$ , m. 86°, difficultly sol. in  $\text{H}_2\text{O}$ , easily sol. in EtOH and  $\text{Et}_2\text{O}$ , insol. in caustic alkali and alk. carbonate solns. Dicyanomalonic Et ester amide imide,  $\text{C}_{10}\text{H}_{10}\text{N}_4\text{O}_6$ , has no definite m. p. (Ag salt,  $\text{C}_{10}\text{H}_8\text{N}_4\text{O}_6\text{Ag}_2$ ; Ba salt,  $\text{C}_{10}\text{H}_8\text{N}_4\text{O}_6\text{Ba} \cdot 6\text{H}_2\text{O}$ ). Dicyanomalonic Me ester amide imide,  $\text{C}_8\text{H}_8\text{N}_4\text{O}_6$ , m. 140° (decompn.). Ag salt, of cyanomalonic benzyl ester amide,  $\text{C}_{11}\text{H}_{11}\text{N}_2\text{O}_5\text{Ag}$ , silky flakes. Dibenzylcyanomalonicate,  $\text{C}_{18}\text{H}_{18}\text{N}_4\text{O}_6$ , m. 73–4° (Na salt,  $\text{C}_{18}\text{H}_{14}\text{N}_4\text{O}_6\text{Na}$ , K salt,  $\text{C}_{18}\text{H}_{14}\text{N}_4\text{O}_6\text{K}$ , Ag salt,  $\text{C}_{18}\text{H}_{14}\text{N}_4\text{O}_6\text{Ag}$ ). Benzylcyanomalonic Et ester anilide,  $\text{C}_{19}\text{H}_{18}\text{N}_2\text{O}_5$ , m. 104.5°. Cyanomalonic Me ester anilide,  $\text{C}_{11}\text{H}_{10}\text{N}_2\text{O}_5$ , m. 146° (Ag salt,  $\text{C}_{11}\text{H}_9\text{N}_2\text{O}_5\text{Ag}$ ). Benzylcyanomalonic Me ester anilide,  $\text{C}_{18}\text{H}_{16}\text{N}_2\text{O}_5$ , m. 103°. Cyanomalonic dianilide,  $\text{C}_{16}\text{H}_{14}\text{N}_4\text{O}_6$ , m. 192° (Ag salt,  $\text{C}_{16}\text{H}_{12}\text{N}_4\text{O}_6\text{Ag}_2$ ; Fe salt,  $(\text{C}_{16}\text{H}_{12}\text{N}_4\text{O}_6)_3\text{Fe}$ ). Benzylcyanomalonic dianilide,  $\text{C}_{20}\text{H}_{18}\text{N}_4\text{O}_6$ , m. 215°. Cyanomalonic dimethylanilide,  $\text{C}_{18}\text{H}_{17}\text{N}_3\text{O}_5$ , m. 178°. Cyanomalonic di-*p*-aniside,  $\text{C}_{18}\text{H}_{17}\text{N}_3\text{O}_6$ , m. 215° (Ag salt,  $\text{C}_{18}\text{H}_{16}\text{N}_3\text{O}_6\text{Ag}$ ). Cyanomalonic di-*m*-toluidide,  $\text{C}_{18}\text{H}_{17}\text{N}_3\text{O}_5$ , m. 186°. Cyanomalonic di-*p*-toluidide, m. 221°. W. O. E.

**Acetylmucates of alcohols and phenols.** T. KARIYONE AND S. MOROTOMI. *J. Pharm. Soc. Japan* **49**, 170–3 (1929).—Boiling of 10 g. tetraacetylmucic acid and 25 cc.  $\text{SOCl}_2$  in 10 cc.  $\text{C}_6\text{H}_6$  on the  $\text{H}_2\text{O}$  bath for 3 hrs. gave 7 g. tetraacetylmucoyl chloride (I), m. 185°, sapon. value, 80.58. I promises to be a useful reagent for the identification of alcs. and phenols. Boiling of 3 g. of I and 2.3 g. menthol in 10 cc. PhMe for 3 hrs. gave 1.2 g. dimenthyl tetraacetylmucate, m. 153°. Heating of 16.5 g. santalol and 15.9 g. I in 30 cc. PhMe gave the monosantalyl ester (II), m. 136°; acid value, 86.8. II may be used as a substitute for santalol. It has the advantage over the latter in being cryst., odorless and non-irritative to the stomach. The following alc. and phenolic esters of I were also prepd.: di-Am ester, m. 105°; dithymyl ester, m. 176°; dicarvacryl ester, m. 175°; dieugenyl ester, m. 175°.

NAO UYEI

**Alkoxoniumhexacyanocobaltates.** FRANZ HÖLZL, THUSNELDA MEIER-MOHAR AND FRIEDRICH VIDITZ. *Monatsh.* **52**, 73–82 (1929).— $\text{H}_3\text{Co}(\text{CN})_6$ , prepd. from the K salt and carefully dried, gives, when dissolved in  $\text{EtOH-H}_2\text{SO}_4$  and treated with dry  $\text{HCl}$ , tert. ethoxoniumhexacyanocobaltate (I),  $\text{Co}(\text{CN})_6 \cdot (\text{H.EtOH})_3$ ; when dry  $\text{HCl}$  is passed into a soln. of I in abs. MeOH there ppts. the sec. methoxonium compd.,  $\text{Co}(\text{CN})_6 \cdot$

H.(H.MeOH)<sub>3</sub>, while in PrOH there is formed the *tert. propoxonium compd.*, Co(CN)<sub>6</sub>-(H.PrOH)<sub>3</sub>. The MeOH compd. is slightly hygroscopic; all 3 compds. are easily sol. in H<sub>2</sub>O but do not crystallize therefrom; the soly. in alcs. increases with increasing mol. wt. of the solvent. These compds. behave as very weak bases; their aq. solns. may be titrated as free acids and their alc. solns. yield salt-like compds. with many org. N bases; the addn. of C<sub>2</sub>H<sub>5</sub>N gives a ppt. of Co(CN)<sub>6</sub>.H<sub>3</sub>.(C<sub>2</sub>H<sub>5</sub>N)<sub>3</sub>. By passing in dry HCl or by adding concd. HCl to H<sub>3</sub>Co(CN)<sub>6</sub> in H<sub>2</sub>O there results a cryst. ppt., probably a hydroxonium salt of the complex acid. The nature of these compds. and the method of their formation are discussed.

C. J. WEST

**Alkylation of tetra- and tricyanocadmium acids.** FRANZ HÖLZL AND SEPP KIRCHMAYR. *Monatsh.* 51, 397-419(1929).—AgCd(CN)<sub>4</sub> was prepd. from the K salt and concd. AgNO<sub>3</sub> and purified by digesting with H<sub>2</sub>O at 60°, from which it crystd. on cooling. Shaken with an excess of MeI at room temp. in the dark for 10 days and extd. with CHCl<sub>3</sub>, there resulted a yellow-brown amorphous mass, purified by repeated crvstn. from MeOH-H<sub>2</sub>O; analysis indicated the compd. Cd<sub>4</sub>C<sub>6</sub>N<sub>6</sub>H<sub>12</sub>O<sub>8</sub>, which may be  $\left[ \left( \begin{smallmatrix} \text{CN} \\ \text{Cd} \\ \text{OH} \\ \text{H}_2\text{O} \end{smallmatrix} \right)_4 \cdot \text{CNMe} \right]$  or  $\left[ \left( \begin{smallmatrix} \text{CN} \\ \text{Cd} \\ \text{OH} \end{smallmatrix} \right)_4 \cdot \begin{smallmatrix} (\text{H}_2\text{O})_4 \\ \text{CNMe} \end{smallmatrix} \right]$ . The aq. soln. shows a slightly alk. reaction; on warming there is a strong isonitrile odor. Various formulas are proposed, showing the possible arrangement of the Cd atoms. If the reaction is carried out as above for 1 week and the product crystd. from dry MeOH, there results the compd.

Cd<sub>4</sub>C<sub>6</sub>N<sub>6</sub>H<sub>12</sub>O<sub>8</sub>, which may be formulated  $\left( \begin{smallmatrix} \text{CN} \\ \text{Cd} \\ \text{OH} \end{smallmatrix} \right)_2 \cdot \text{CNMe}$ , for which 2 formulas are proposed. The primary intermediate product of both compds. is assumed to be  $\left( \begin{smallmatrix} (\text{CN})_2 \\ \text{Cd} \\ \text{CNMe} \end{smallmatrix} \right)$ . The action of Me<sub>2</sub>SO<sub>4</sub> upon the K salt gives the compd. Cd<sub>3</sub>C<sub>9</sub>N<sub>7</sub>H<sub>7</sub>O<sub>7</sub>,

obtained by crystg. the solid reaction product from dry MeOH; the mother liquor contains the compd. [Cd(CNMe)<sub>4</sub>(MeSO<sub>4</sub>)<sub>2</sub>] or [Cd(CNMe)<sub>3</sub>(MeSO<sub>4</sub>)<sub>2</sub>]. If the above reaction is carried out at an elevated temp., there is a complete decompn. of the complex. A satd. soln. of the K salt and Me<sub>2</sub>SO<sub>4</sub>, shaken in the cold for 2 days, give the compd. Cd<sub>3</sub>C<sub>9</sub>H<sub>7</sub>N<sub>7</sub>O<sub>7</sub>, for which also various formulas are proposed. EtI and the Ag salt do not react at room temp.; at elevated temps. decompn. occurs. The original should be consulted for the discussion of the formulas proposed for these compds.

C. J. WEST

**Ureides of brominated derivatives of valeric acid.** ST. WEIL, (MISS) J. LANGHERT AND A. KASSUR. *Roczniki Chem.* 9, 464-9(469-70 French)(1929).—Ureides of brominated  $\alpha$ -methylisovaleric and  $\alpha$ -ethylisovaleric acids were prepd. and studied. No stronger narcotic action on rats and cats was found than that exhibited by the brominated ureide of isovaleric acid. The following compds. were prepd.:  $\alpha$ -bromo- $\alpha$ -methylisovaleryl bromide, Me<sub>2</sub>CHCBrMeCOBr, obtained by mixing 25.0 g. methylisovaleric acid with 2.5 g. red P, adding to the mixt. 75.0 g. Br and subsequently heating on the water bath to 90-100° till no HBr was evolved; b<sub>16</sub> 130°, sol. in ether and CHCl<sub>3</sub>;  $\alpha$ -bromo- $\alpha$ -ethylisovaleryl bromide, similarly prepd., b<sub>20</sub> 145°; menthyl  $\alpha$ -bromo- $\alpha$ -methylisovalerate decomps. easily in the light, b<sub>20</sub> 173-5°, sol. in alc., ether and CHCl<sub>3</sub>; menthyl  $\alpha$ -bromoethylisovalerate, decomps. on exposure to the light, b<sub>11</sub> 161°;  $\alpha$ -bornyl bromo- $\alpha$ -methylisovalerate, b<sub>12</sub> 170°, sol. in alc., ether and CHCl<sub>3</sub>, decomps. in the air; bornyl  $\alpha$ -bromo- $\alpha$ -ethylisovalerate, becomes dark in the air and light, b<sub>10</sub> 178°;  $\alpha$ -bromo- $\alpha$ -methylisopropylacetic ureide, Me<sub>2</sub>CHCMeBrCONHCONH<sub>2</sub>, sol. in alc., m. 177-9°;  $\alpha$ -bromo- $\alpha$ -methylisovaleric ureide, m. 197°. J. KUČERA

**The action of heat on allophanic amides.** J. BOUGAULT AND J. LEBOUCC. *Compt. rend.* 188, 1406-7(1929).—The allophanic amides (I) (II) and (III) resp., corresponding to PhNH<sub>2</sub>, *p*-toluidine, and PhNHNH<sub>2</sub>, were prepd. from allophanic chloride, NH<sub>2</sub>CONHCOCl, and the amine. Heated to 200-10°, I and II decompd. into NH<sub>3</sub>, cyanuric acid, and a sym. disubstituted urea ((PhNH)<sub>2</sub>CO from I and *p*-(MeC<sub>6</sub>H<sub>4</sub>NH)<sub>2</sub>CO from II); III (new), m. 218°, formed NH<sub>3</sub> and phenylurazole, PhN.CO.NH.CO.NH,

m. 267°, prepd. (as also the di-Me ether, m. 88-9°) by Pinner's method (*Ber.* 20, 2358; 21, 1223) for identification.

**Recent progress in the chemistry of glucides.** P. CASTAN. *Rev. gén. sci.* 40, 361-8(1929).

E. H.

**The cleavage of sugars by alkali.** F. FISCHLER. *Z. angew. Chem.* 42, 682-4 (1929).—Hexoses and other sugars yield trioses (methylglyoxal) (I) when treated with

cold alkali as shown by an  $\text{CHI}_3$  test. This test works well with glucose (II), mannose, lactose, and maltose, less easily with galactose. With fructose, arabinose and xylose the test is very weak. The pentoses are thought to yield glycolaldehyde which consumes the KIO and hinders  $\text{CHI}_3$  formation. Sucrose gives as strong a test as II but requires more time. The reducing action of sugars in alk. solns. is ascribed to their decompn. products. The behaviors of  $\text{CO}(\text{CH}_2\text{OH})_2$  (III), I and II in sulfite-Ost soln. are compared. III is thought to yield I in this soln. The aldo- and keto-structure of the sugars is not questioned. G. C. STROUSE

**Oxidation of sugars in alkaline solution by oxygen.** Influence of  $p_{\text{H}}$  on the production of carbon monoxide. MAURICE NICLOUX AND H. NEBENZAHL. *Compt. rend. soc. biol.* 101, 189-92(1929).—Fructose, galactose and glucose were stored 2-4 days at  $38-40^\circ$  in contact with excess  $\text{O}_2$  and 0.66  $M$  phosphate buffer solns. of  $p_{\text{H}}$  7.38, 7.73, and 8.04 (250 mg. carbohydrate to 20 cc. buffer soln.). The max. vol. of CO produced was, at  $p_{\text{H}}$  7.38: fructose 0.64 cc., galactose 0.38 cc. and glucose 0.16 cc.  $\text{O}_2$  consumption paralleled CO production. Negative results were obtained using 0.066  $M$  phosphate buffer solns. The results support N. and N.'s theory that CO, found in mammalian blood, is a normal metabolic product, derived from the biol. oxidation of carbohydrates. B. C. BRUNSTETTER

**The oxidation of different sugars in alkaline solution by oxygen from the point of view of carbon monoxide production.** MAURICE NICLOUX AND H. NEBENZAHL. *Compt. rend. soc. biol.* 100, 864-6(1929); cf. C. A. 22, 2742, 3179, 3180, 3633.—Arabinose, fructose and galactose in 250 mg. amts. were each shaken 5 min. at  $84-85^\circ$  with 50 cc. 0.1  $N$  KOH and 40-50 cc.  $\text{O}_2$ . The av. production of CO was: arabinose 1.9 cc., galactose 2.1 cc., and fructose 2.4 cc. B. C. BRUNSTETTER

**The oxidation of carbohydrates by molecular oxygen. Study of the action of phosphates.** MAURICE NICLOUX AND H. NEBENZAHL. *Compt. rend. soc. biol.* 101, 720-2(1929).—Under the exptl. conditions noted in the preceding abstract, fructose, glucose and galactose in borate buffer solns. at  $p_{\text{H}}$  7.36 and 7.8 are not oxidized by  $\text{O}_2$ . The subsequent addn. of phosphate buffer ( $p_{\text{H}}$  7.4) to the soln. of fructose and borate buffer resulted in the oxidation of fructose. B. C. BRUNSTETTER

**3-Acetylmonoacetoneglucose and its transformation into 6-acetylmonoacetoneglucose.** KARL JOSEPHSON. *Svensk. Kem. Tid.* 41, 99-106(1929); cf. C. A. 23, 2943.—3-Acetylmonoacetoneglucose (I) is obtained by the treatment of 3-acetyldiacetoneglucose (II) with 75% HOAc followed by subsequent concn. under diminished pressure and recrystn. from EtOAc and petroleum ether (5 g. of II in 10 cc. of HOAc and 3 cc. of  $\text{H}_2\text{O}$  gave after 4 days 2.7 g. of I, corresponding to a 62% yield). I m.  $125.6^\circ$  (cor.),  $[\alpha]_{\text{D}}^{20} = -20^\circ$ . I reverts back to II upon treatment with anhyd. acetone and  $\text{CuSO}_4$ . The stability of I is dependent upon the  $\text{OH}^-$  concn., and even in slightly acid or neutral soln. the transformation of I into the isomeric 6-acetylmonoacetoneglucose (III) proceeds with noticeable rapidity. The velocity of the migration of the acyl group in the transformation of I and II can be followed by polarimetric measurements where the  $p_{\text{H}} = 5.5-8$ , but is already too rapid where  $p_{\text{H}}$  exceeds 9. The data indicate that the transformation velocity is of the same order of magnitude as the mutarotation of a reducing sugar. L. F. AUDRIETH

**Synthesis of sucrose.** GÉZA ZEMPLÉN AND ÁRPÁD GERECs. *Ber.* 62B, 984 (1929).—Irvine, Oldham and Skinner (C. A. 22, 2552) state that the condensation of  $\gamma$ -tetraacetylfructose and tetraacetylglucose under the influence of  $\text{P}_2\text{O}_5$  does not yield sucrose. Z. and G., in similar expts. in connection with a study of the synthesis of sucrose as reported by Pictet and Vogel, observed that disaccharide formation, to the extent of 10-15%, takes place but they were never able to isolate octaacetylsucrose, even on seeding the different fractions contg. the disaccharide mixt. Control expts. showed that even from a mixt. of 50% octaacetylsucrose and 50% tetraacetylglucose or  $\gamma$ -tetraacetylfructose the acetylated sucrose cannot be isolated because of its sensitivity to foreign substances. Evidently quite subtle conditions, which cannot be gotten from P. and V.'s description, are essential for the isolation of the substance. C. A. R.

**Syntheses in the carbohydrate group with the aid of sublimed ferric chloride.** I. Preparation of the biosides of the  $\alpha$ -series. GÉZA ZEMPLÉN. (WITH ZOLTÁN BRUCKNER AND ÁRPÁD GERECs). *Ber.* 62B, 985-90(1929).—In a study of the action of sublimed  $\text{FeCl}_3$  on acetylated sugars in  $\text{CHCl}_3$  Z. found that there was no conversion into aceto-halogen derivs. as with  $\text{TiCl}_4$  (cf. Pacsu, C. A. 22, 4479) but neither were the products identical with the starting materials.  $\alpha$ -Octaacetylcellobiose (I) and  $\beta$ -octaacetylmaltose (II) were studied especially, and the products were found to be heptaacetyl- $\alpha$ -ethylcellobioside (III) and heptaacetyl- $\alpha$ -ethylmalloside (IV), resp. Under the influence

of the alc. in the  $\text{CHCl}_3$  the I and II in the presence of  $\text{FeCl}_3$  split off  $\text{AcOH}$  and form the biosides which, surprisingly enough, are of the  $\alpha$ -series, so that octaacetylbiobioses can be converted directly into acetylated  $\alpha$ -biosides. In alc.-free  $\text{CHCl}_3$  not a trace of bioside is formed. From 100 g. I refluxed in  $\text{CHCl}_3$  about 1 hr. with 15 g.  $\text{FeCl}_3$ , there can regularly be obtained 6-7 g. crystals with a reducing power 2-3% that of glucose. III, m. 169-70°,  $[\alpha]_D^{16}$  49.7° ( $\text{CHCl}_3$ ), reducing power before hydrolysis 2.1-2.27% that of glucose, after hydrolysis 52%, mol. wt. (Rast) 628, is smoothly converted in  $\text{CHCl}_3$  by  $\text{HBr-AcOH}$  at 18° into acetobromocellobiose, m. 180° (decompn.),  $[\alpha]_D^{19}$  90.5° ( $\text{CHCl}_3$ ). Refluxed in  $\text{CHCl}_3$  with  $\text{TiCl}_4$  (which converts  $\beta$ - into  $\alpha$ -glucosides), III gave a product m. 174°,  $[\alpha]_D^{15}$  52.6° ( $\text{CHCl}_3$ ); the small increase in the rotation indicates that the III consists chiefly of the  $\alpha$ -compd., although it is not quite pure, since it still has a slight reducing power and moreover a sample of the  $\beta$ -isomer, with a reducing power of 2.6%, that of glucose and  $[\alpha]_D^{18}$  -19.5° gave with  $\text{TiCl}_4$  a product m. 171°, with  $[\alpha]_D^{17}$  55.6°. IV (133 g. from 150 g. II), powder, sinters 80-5°, m. 90-100°, reducing power 2.3%, before, 51.3% after hydrolysis,  $[\alpha]_D^{17}$  122.2° ( $\text{CHCl}_3$ ), gives with  $\text{TiCl}_4$  a product with  $[\alpha]_D^{17}$  124.4° ( $\text{CHCl}_3$ ). C. A. R.

**Action of aluminum metal and mercuric salts on acetohalogensugars. I. Synthesis of  $\alpha$ -biosides.** GÉZA ZEMPLÉN (WITH ÁRPÁD GERÉCS). *Ber.* 62B, 990-3 (1929), cf. preceding abstr.—Acetobromocellobiose (I) heated in  $\text{C}_6\text{H}_6$  with Al and dry  $\text{Hg}(\text{OAc})_2$  rapidly splits off its Br and gives heptaacetylcellobiose in good yield; in abs. alc. is obtained heptaacetyl- $\alpha$ -ethylcellobioside (II). If PhOH is dissolved in the  $\text{C}_6\text{H}_6$ , heptaacetyl- $\alpha$ -phenylcellobioside (III) is obtained in such pure form that heating with  $\text{TiCl}_4$  does not raise its rotation; with  $\text{HBr-AcOH}$  it smoothly regenerates I, showing that the cellobiose has undergone no transformation or rearrangement in the reaction. The II (88.4% yield) m. 186°,  $[\alpha]_D^{18}$  -19.44° ( $\text{CHCl}_3$ ). III (32.4% yield), m. 217°, reducing power nil before, 50.5% that of glucose after reduction,  $[\alpha]_D^{17}$  81.10° ( $\text{CHCl}_3$ ). In the same way was obtained heptaacetyl- $\alpha$ -cyclohexylcellobioside (63% yield), m. 203.5°, reducing power nil before, 48.2% after hydrolysis,  $[\alpha]_D^{20}$  63.4° ( $\text{CHCl}_3$ ). C. A. R.

**Cleavage of levoglucosan with titanium tetrachloride.** GÉZA ZEMPLÉN AND ZOLTÁN CSÜRÖS. *Ber.* 62B, 993-6 (1929).—Glucose derivs. with a free HO group in the 6-position can readily be obtained by heating triacetyllevoglucosan (I) in  $\text{CHCl}_3$  with an excess of  $\text{TiCl}_4$ ;  $\alpha$ -1-chloro-2,3,4-triacetylglucose (II) is thus formed with no detectable complication, for with  $\text{C}_6\text{H}_5\text{N-AcOH}$  it smoothly gives  $\alpha$ -acetoethylglucose; with  $\text{MeOH}$  and  $\text{Ag}_2\text{CO}_3$  the II yields  $\beta$ -1-Me 2,3,4-triacetylglucoside (III). With  $\text{Ag}_2\text{CO}_3$  in  $\text{C}_6\text{H}_6$  is obtained a tetra-Ac compd. giving a  $\text{MeC}_6\text{H}_4\text{SO}_2$  deriv. identical with Helfferich and Klein's 1,2,3,4-tetraacetyl-6-toluenesulfonyl- $\beta$ -d-glucose. Attempts to convert tribenzoyllevoglucosan into an analogous Cl deriv. failed completely. Under the same conditions as were used to prep. II the substance was recovered unchanged. Pentabenzoylglucose behaves normally, smoothly yielding tetrabenzoyl-1-chloroglucose. Trimethyllevoglucosan gives an amorphous product which contains only 2.2-2.7% Cl; 2,3,4,6-tetramethylglucose decomps and no definite product could be isolated, pentaacetylgluconitrile and hexaacetylmannitol are unchanged. II (33 g. from 50 g. I), m. 124-5°,  $[\alpha]_D^{19}$  191.5° ( $\text{CHCl}_3$ ). III (14 g. from 30 g. II), m. 131-2°,  $[\alpha]_D^{19}$  -13.59° ( $\text{CHCl}_3$ ). C. A. R.

**1,2-Dimethylcyclopropane.** JEAN BAUDRENHIEU. *Bull. sci. acad. roy. Belg.* 15, 53-80 (1929).—In the prepn. of 3-penten-2-ol (I) from  $\text{MeCH:CHCHO}$  and  $\text{MeMgBr}$ , decompn. of the reaction product with dil.  $\text{H}_2\text{SO}_4$  gives mainly  $(\text{MeCH:CHCHMe})_2\text{O}$  (II),  $d_{20}$  0.8047,  $n_D^{20}$  1.4306. The decompn. of the reaction product with water gives 75% I (without II), b. 122°,  $d_{20}$  0.8375,  $n_D^{20}$  1.4277.  $\text{MeCH}(\text{OAc})\text{CH:CHMe}$  (III) is obtained from I and  $\text{Ac}_2\text{O}$ ,  $b_{773}$  138.5-9°,  $d_{20}$  0.8962,  $n_D^{20}$  1.4163.  $\text{MeCHClCH:CHMe}$  (IV), obtained from I and  $\text{HCl}$ ,  $b_{771}$  100.5°,  $d_{20}$  0.8980,  $n_D^{20}$  1.4332. I and  $\text{HBr}$  give  $\text{MeCHBrCH:CHMe}$  (impure) (V), b. 117-20°, decompd. by water, transformed to a resin by  $\text{P}_2\text{O}_5$ . I and  $\text{PBr}_3$  in  $\text{CS}_2$  give 69% of a mixt. of isomeric bromides. IV and  $\text{HBr}$  give an unsatd. bromide, addn. to the double bond occurring very slowly and not being enhanced by sun or ultra-violet light. The  $\text{HBr}$ -treated product after distn and subsequent treatment with  $\text{HBr}$  gives a mixt. (VI) of 2,3- and 2,4-dibromopentanes, this being explained on the basis that the distn. removes a negative catalyst. III (prepd. from V and  $\text{KOAc}$ ) and  $\text{HBr}$  give a mixt. of dibromopentanes similar to the foregoing. III (prepd. from I and  $\text{Ac}_2\text{O}$ ) and  $\text{HBr}$  give  $\text{MeCHBrCH:CHMe}$  (VII). VII (distd.) and  $\text{HBr}$  give a mixt. of dibromopentanes richer in the 2,4-isomer than VI, which, when distd. over  $\text{P}_2\text{O}_5$ , decomps. giving a pentadiene, b. 40°,  $\text{AcOH}$ , and a resin. VI and Zn

in aq. alc. give  $\text{MeCH:CHEt}$  (44%) and  $\text{CH}_2\text{CHMe.CHMe}$  (VIII).  $\text{MeCH(OH)CH}_2\text{-}$

$\text{COMe}$  (IX) and H in the presence of Pt black give  $\text{MeCH(OH)CH}_2\text{CH(OH)Me}$  (X). X is also obtained from aldol and  $\text{MeMgBr}$ . Reduction of  $\text{CH}_2\text{Ac}_2$  (XI) with H, using Pt black, gives X (30%) and  $\text{MeCH(OH)CH}_2\text{Et}$ . Hydrogenation of XI, using Pt black activated with a trace of Fe, gives a mixt. of X and IX. The use of the Pt-Fe catalyst of Adams and Carothers gave poor results. Reduction of XI with Na and alc. gives 70% X and is the best of the methods tried. VIII obtained from VI and Zn consists of two isomeric 1,2-dimethylcyclopropanes (explained on the basis of the presence of asym. C atoms) which were sep'd. by fractional distn., one  $b_{755}$  28.8–29°,  $d_{4-20}$  0.6985,  $n_{D-20}$  1.39641, 1.37129, 1.37617, 1.37997, and the other  $b_{755}$  37.2–4°,  $d_{4-20}$  0.71325, 0.6928,  $n_{D-20}$  1.38023, 1.38223, 1.38702, 1.39109. Also in *Bull. soc. chim. Belg.* 38, 172–93 (1929). F. C. H.

**Oxidation of organic halogen compounds.** CH. COURTOT AND J. PIERRON. *Bull. soc. chim.* 45, 286–93 (1929); cf. C. A. 22, 738 and following abstr.—Compds. which are easily oxidized to ketones or aldehydes possess a Cl atom in the  $\alpha$ -position to a double bond ( $\alpha$ -chloroindene,  $\text{PhCH}_2\text{Cl}$ ). C. and P. verify a theory of Grimaux and Lauth (1877) that mobility of the Cl, the ease with which they hydrolyze, leads to alics. which in turn are readily oxidized. The following exptl. examples are given: 1-chloro-2-cyclohexene hydrolyzed in water at 15° within 48 hrs. or in 75 min. at 65°. The Cl compd. (12 g.) was emulsified in 200 cc. water and 20 g.  $\text{Na}_2\text{Cr}_2\text{O}_7$ , at 60–65°, 30 g. concd.  $\text{H}_2\text{SO}_4$  slowly added, the soln. extd. with ether, and the cyclohexenone dried, rectified,  $b_{74}$  63°; yield 60%. 9-Chlorofluorene hydrolyzed above its m. p., 92° (not below), in less than 1 hr. in pure water. Oxidation of the chloride to fluorenone occurred only at the temp. of hydrolysis. 4-Chloro-2-hexene was oxidized to 2-hexen-4-one (yield 55%),  $d_4^{14}$  0.8838,  $n_D^{15}$  1.4380; M. R. calcd. 29.45, found 29.11. 5-Chloro 4-methyl-3-heptene (like the other examples easily saponifiable) gave 4-methyl-3-hepten-5-one (I) in poor yield, due to simultaneous formation of 4-methyl-3,5-heptadiene. I  $b_{70}$  96.8°,  $b_{735}$  170–2°,  $d_4^{15}$  0.8773,  $n_D^{15}$  1.4510, M. R. calcd. 38.71, found: 38.68. Oxidation of chlorides may assume a practical value since they are readily accessible by addn. of HCl to polyethylene compds. K. H. ENGEL

**$\alpha$ -Ethylenic chlorides and alcohols.** CH. COURTOT AND J. PIERRON. *Compt. rend.* 188, 1501–4 (1929).—Secondary  $\alpha$ -ethylenic chlorides have previously been converted to the corresponding ketones by the action of a mixt. of  $\text{CrO}_3$  and  $\text{H}_2\text{SO}_4$ . To the examples previously given (cf. preceding abstr.) one more is added here.  $\text{PhCHCl-CH}_2\text{Me}$  is converted to the ketone  $\text{PhCOCH}_2\text{Me}$  with 75% yield. The benzene double bond in the  $\alpha$ -position to the Cl does not render it as mobile as an ordinary ethylenic linkage. It is 97% hydrolyzed at 68° in 75 min. Treatment of  $\text{CH}_2\text{:CHCH(OH)Et}$  with the  $\text{CrO}_3\text{-H}_2\text{SO}_4$  at 34–35° gives the corresponding ketone in 45% yield. The immediately higher homolog treated at 40–45° gives the  $\text{CH}_2\text{:CHCOPr}$  in 44% yield. The phys. consts. of the 2 ketones are:  $\text{CH}_2\text{:CHCOEt}$ ,  $b_{200}$  68–70°,  $d_4^{15}$  0.8524,  $n_D^{14}$  1.4275;  $\text{CH}_2\text{:CHCOPr}$ ,  $b_{150}$  88–90°,  $d_4^{15}$  0.8518,  $n_D^{14}$  1.4275.  $\text{NHEt}_2$  attaches itself to the 2 ketones. The *picrates* of these addn. products m. 78° and 81°, resp. R. P. W.

**Constitution of aromatic substances and their chemical and physical properties.** VI. Crystal symmetry. I. PASTAK. *J. chim. phys.* 26, 65–8 (1929); cf. C. A. 20, 1601—From previous comparisons of m. ps. and relative solubilities predictions are made as to the relative degree of crystal symmetry of isomeric disubstituted benzenes (with the same, and with diff. substituents), of isomeric disubstituted biphenyls and of a few  $\alpha$ - and  $\beta$ -naphthalene derivs., the lower-melting, more highly sol. compd. possessing the greater degree of symmetry. Known crystallographic information, (classifications) is cited in support. K. H. ENGEL

**The dipole moments of mono- and disubstituted benzene derivatives.** P. WALDEN AND P. WERNER. *Z. physik. Chem., Abt. B*, 2, 10–26 (1929).—Data are presented on the dielec. consts. and dipole moments of  $\text{PhF}$ ,  $\text{PhI}$ , *o*-, *m*-, and *p*- $\text{C}_6\text{H}_4\text{Br}$ , *o*-, *m*- and *p*- $\text{C}_6\text{H}_4\text{BrI}$ , *o*-, *m*- and *p*- $\text{MeC}_6\text{H}_4\text{Cl}$ , and *o*-, *m*- and *p*- $\text{C}_6\text{H}_4\text{ClNO}_2$ , as detd. in benzene as a non-polar solvent. A very good agreement is shown between the exptl. and calcd. values. For compds. with similar (in elec. nature) substitutions the moment is: *o*-position =  $a\sqrt{3}$ ; *m*-position =  $a$ ; and *p*-position = 0. For compds. with different substitutions the moment is, *o*-position =  $\sqrt{a^2 + b^2 + ab}$ ; *m*-position =  $\sqrt{a^2 + b^2 - ab}$ ; and *p*-position =  $a-b$ , where  $a$  and  $b$  are detd. from the sep. moments of monosubstituted compds. The order of moments in similar disubstituted compds. is  $o > m > p$  (i. e.,  $\text{C}_6\text{H}_4\text{Cl}_2$ , etc.) and in unlike disubstituted compds.  $p > m > o$  (i. e.,  $\text{MeC}_6\text{H}_4\text{Cl}$ ). WALLACE R. BRODE

**Reduction of aromatic nitro compounds by hydrogen in the presence of platinum black.** V. VESELY AND E. REIN. *Collection Czechoslov. Chem. Comm.* **1**, 360-7 (1929). (In French).—See *C. A.* **22**, 1352.

**Nitration of bromoaniline in sulfuric acid.** R. LUKEŠ AND J. FRAGNER. *Collection Czechoslov. Chem. Comm.* **1**, 294-301 (1929).—Nitration of *o*-bromoaniline in excess of concd.  $\text{H}_2\text{SO}_4$  gives 2,5-Br( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{NH}_2$ ; *m*-bromoaniline gives 3,4-Br( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{NH}_2$  (I), m. 173-4°, and some 3,6-compd. The m. p. of 2,3,6,4-Br( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{NH}_2$  is 159°; previous reports were 131° (*J. prakt. Chem.* **56**, 61).

**Photochemical formation of ammonium salts.** A. K. PLISSOV. *Gazz. chim. ital.* **59**, 200-6 (1929).—A review and discussion of the relation of the quantum theory to photochem. reactions in general and to various hypotheses of the formation of  $\text{NH}_4$  salts from amines and alkyl halides leads to the conclusion that in the latter reaction both the halide and the amine are activated. There is a complete series of photochem. reactions where halogenated derivs. react with non-N compds., and where the yields are increased notably by illumination. Therefore, in the formation of  $\text{NH}_4$  salts, frequencies which activate the halide may also activate the amine. Studies of absorption spectra have already shown that the substitution of H in the amine does not change the general character of the absorption curve either in the infra-red or ultra-violet. Accordingly,  $\text{PhNH}_2$  and its derivs. should, when activated during the formation of  $\text{NH}_4$  salts, absorb radiation of the same frequency. This means that the ratio of the velocity consts. for 2 different temps. should be const., as found by Marcelin and Reiss for various amines. If in the formation of  $\text{NH}_4$  salts the halide is activated, the results are far different. To study this problem,  $\text{PhCH}_2\text{Cl}$ ,  $\text{EtBr}$  and  $\text{CH}_2\text{:CHCH}_2\text{Cl}$  were chosen, because they should possess different absorption spectra. In the activation of alkyl halides, radiation of different frequencies should be absorbed, and the ratio of the velocity consts. for 2 different temps. is the same if the same alkyl halide reacts with different amines, and is different if the same amine reacts with different halides. If only the amine is activated, then when the reaction is accelerated by radiation, the ratio: *yield in darkness/when irradiated*, should be const., regardless of the amine or of the alkyl halide. If, on the other hand, both amine and alkyl halide are activated, then the ratio: *yield in darkness/when irradiated*, should be const. for a given alkyl halide with different amines, and should vary for a given amine with different alkyl halides. In the initial expts. the reactions between  $\text{PhCH}_2\text{Cl}$  and  $\text{PhNH}_2$  and *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , resp., were studied. The reaction between  $\text{PhCH}_2\text{Cl}$  and  $\text{PhNH}_2$  (2 mols.) was carried out in  $\text{C}_6\text{H}_6$ , at 46° in a quartz receptacle, irradiation being from a voltaic arc. Control tests were run simultaneously in glass with irradiation, and in darkness. After 1.5 hrs. in quartz, the yield of  $\text{PhNH}_3\text{Cl}$  was 51% of the theoretical, and after 3 hrs. it was 82%. After 1.5 and 3 hrs. in glass the yields were 7% and 19%, resp., and in darkness were 6.3% and 15%, resp. The reaction between  $\text{PhCH}_2\text{Cl}$  and *o*- $\text{MeC}_6\text{H}_4\text{NH}_2$  (2 mols.) was also carried out in  $\text{C}_6\text{H}_6$ , but the temp. was 32° and the radiation much weaker. After 3 hrs. in quartz, the yield of *o*- $\text{MeC}_6\text{H}_4\text{NH}_3\text{Cl}$  was 12% and in darkness 5.5%. The results show that ultra-violet light accelerates greatly the formation of  $\text{NH}_4$  salts from alkyl halides and amines, particularly with  $\text{PhNH}_2$ . Further expts. are to be described with  $\text{EtBr}$  and  $\text{CH}_2\text{:CHCH}_2\text{Cl}$  in place of  $\text{PhCH}_2\text{Cl}$ .

**Nitrations. I. Thermal analysis of the anilides.** FRANCIS ARNALL. *J. Soc. Chem. Ind.* **48**, 157-9T (1929); cf. *C. A.* **18**, 674, 2142.—Nitration of *acetanilide* (I) gave a mixt. (II) contg. *o*-, *m*-, and *p*-nitroacetanilide and some unchanged I. Depressions of the f. p. resulting from the soln. of 0.5 g. of II in 5 g. of each of the pure *o*-, *m*-, and *p*-isomerides and in pure I were detd. Titration of II with  $\text{TiCl}_3$  gave the degree of nitration. Binary fusion curves of the pure compds. contg. small amts. of other isomerides showed that when using the *p*-compd. as solvent, 1° depression = 1.46% of *m* + *o* (the two being equiv. since their mol. wts. are the same); using *m* as solvent, 1° = 1.67% of *p* + *o*; and in *o*, 1° = 2.1% of *p* + *m*. The f. p. in pure I gave the degree of nitration (1° = 1.7%  $\text{O}_2\text{NC}_6\text{H}_4\text{NHAc}$ ) and should agree with the  $\text{TiCl}_3$  value, otherwise an impurity such as the dinitro deriv. is indicated. The depression in  $p = o + m + u$  (unchanged I). *u* was known from the  $\text{TiCl}_3$  value and the quantity of nitro deriv. causing the same f. p. depression was calcd. from their resp. mol. wts. (1 g. of I = 1.33 g. of nitro deriv.). Correcting the 3 equations for *u*, the quantities of *o*, *m*, and *p* were calcd. II. Nitration of the anilides. FRANCIS ARNALL AND THOMAS LEWIS. *Ibid* 159-60T.—Ten g. of anilide was dissolved in 30 cc. of concd.  $\text{H}_2\text{SO}_4$  and nitrated at 20° with the calcd. quantity of  $\text{HNO}_3$  (d. 1.42) in 25 cc. of  $\text{H}_2\text{SO}_4$ . After 12 hrs., this was dild.; boiled to eliminate the acyl group; cooled and neutralized with  $\text{NaOH}$ . The pptd.  $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$  was filtered off and the dissolved portion removed

by exhaustive  $\text{Et}_2\text{O}$  extn. The combined product was refluxed with 50 cc. of  $\text{Ac}_2\text{O}$  and 1 drop of  $\text{H}_2\text{SO}_4$ ; after hydrolyzing the excess  $\text{Ac}_2\text{O}$ , the soln. was made alk. with ice  $\text{NaOH}$  and extd. with  $\text{Et}_2\text{O}$ . The resulting  $\text{O}_2\text{NC}_6\text{H}_4\text{NHAc}$  was analyzed for (a) degree of nitration, (b) total yield, (c) *o*-deriv., (d) *m*-deriv., (e) *p*-deriv., giving the following results: nitration of *formanilide* (a) 97%, (b) 97.3%, (c) 18.1%, (d) 2.0%, and (e) 79.7%; *acetanilide* (a) 95.9%, (b) 97.7%, (c) 19.4%, (d) 2.1%, and (e) 78.5%; *propionanilide* (a) 94%, (b) 95.1%, (c) 21.1%, (d) 1.2% and (e) 77.7%; *N-benzalaniline* (a) 99%, (b) 95.6%, (c) 5.5%, (d) 0.6%, and (e) 93.9%. In the same manner nitrations were carried out in  $\text{Ac}_2\text{O}$  instead of  $\text{H}_2\text{SO}_4$ , adding  $\text{H}_2\text{SO}_4$  for the hydrolysis of the acyl group; the following data were obtained:  $\text{O}_2\text{NC}_6\text{H}_4\text{NHAc}$  (a) 86%, (b) 90.5%, (c) 67.8%, (d) 2.5%, and (e) 29.7%;  $\text{O}_2\text{NC}_6\text{H}_4\text{NHCOEt}$  (a) 78%, (b) 80%, (c) 65.8%, (d) 2.2%, and (e) 32.0%. Radiation from a Hg-vapor arc did not vary the results.

A. S. CARTER

The action of diazotates on azoxyphenols. D. BIGIARI AND S. STEFANIC. *Atti accad. Lincei* [6], 9, 326-31 (1929).—Of the 2 isomers of *p*-hydroxyazoxybenzene, the  $\beta$ -form reacts in many ways like *p*-nitrophenol (I):  $\text{PhN}(\text{:O}): \text{NC}_6\text{H}_4\text{OH}$  ( $\alpha$ ),  $\text{PhN}(\text{:O}): \text{NC}_6\text{H}_4\text{OH}$  ( $\beta$ ) and  $\text{O}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{OH}$  (I). *E. g.*, oxidizing agents, as  $\text{KMnO}_4$  in alk. soln., oxidize the  $\alpha$ -form, whereas the  $\beta$ -form as well as I are stable, the  $\alpha$  derivs. are similar, the  $\alpha$ -deriv. only being readily oxidizable.  $\text{HNO}_2$  on the  $\alpha$ -form gives a mono- $\text{NO}_2$  deriv., the other 2 are not affected. The following reaction of I with diazo-hydrates  $\text{BrC}_6\text{H}_4\text{N}_2\text{OH} + \text{HOC}_6\text{H}_4\text{NO}_2 \rightarrow \text{BrC}_6\text{H}_4\text{N}:\text{N}.\text{O}.\text{C}_6\text{H}_4\text{NO}_2 \rightarrow \text{BrC}_6\text{H}_4\text{N}:\text{NC}_6\text{H}_4(\text{OH})\text{NO}_2$  (II) is also shown by the  $\beta$ -form, a diazo-ether being the intermediate product. The  $\alpha$ -form, however, forms the hydroxyazo compd. directly. The structure of II has been proven by reducing with Sn and HCl, the products being *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$ , and 2,4-( $\text{H}_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{OH}$ .

A. W. CONTIERI

Determination of the acidity of undissociated acids with dimethylaminoazobenzene as indicator. A. HANTZSCH AND W. VOIGT. *Ber.* 62B, 975-84 (1929).—Earlier work by H. showed that the strengths of acids cannot be calcd. purely physically according to the classical dissoen. theory from their cond. in  $\text{H}_2\text{O}$  because in this solvent they form hydroxonium salts. Their true acidity can be detd. only chemically on the basis of their tendency to salt formation or, which is in principle the same but in practice more convenient, on the basis of the stability of their salts which decompose according to the simple scheme  $\text{X}[\text{HNR}_3] \rightarrow \text{XH} + \text{NR}_3$  for  $\text{NH}_4$  salts. The decompn. can be followed most easily experimentally when the formation and decompn. of the salts is accompanied by a change in color as the result of intramol. rearrangement, *i. e.*, when indicator base anhydrides are used as the basic constituent of the salt. For this purpose was chosen dimethyl yellow,  $\text{PhN}:\text{NC}_6\text{H}_4\text{NMe}_2$  (I). The position of the equil.  $\text{PhN}:\text{NC}_6\text{H}_4\text{NMe}_2 + \text{HX} \rightleftharpoons \text{PhNHN}:\text{C}_6\text{H}_4:\text{NMe}_2\text{X}$  is dependent primarily on the strength of the acid but is also influenced by the nature of the "solvent," especially its dissoen. power or dielec. const. Only the satd. hydrocarbons and, to a lesser degree, their halogen derivs. ( $\text{CCl}_4$ ,  $\text{CHCl}_3$ ) act almost entirely merely as diluents, whereas all O-contg. solvents react chemically with the acids. The strongest acids ( $\text{HClO}_4$ ,  $\text{HI}$ ,  $\text{HBr}$ ) dissolve as oxonium salts; somewhat weaker acids ( $\text{HCl}$ ,  $\text{HNO}_3$ ) are also present in  $\text{H}_2\text{O}$  and alc. solns. of moderate concn. entirely as oxonium salts while in  $\text{Et}_2\text{O}$  at room temp. they dissolve only as etherates and remain in the state of homopolar, ester-like non-electrolytes; the weaker acids the more extensively do they remain, even in  $\text{H}_2\text{O}$ , at high dilns., partially as non-dissociating acid hydrates. For the present work  $\text{Et}_2\text{O}$  and  $\text{CHCl}_3$  were chosen as representatives of the 2 kinds of solvents. Naturally, they had to be freed of  $\text{H}_2\text{O}$  as completely as possible. The I salts of the strong acids were prepd. by pptg. with petroleum ether from  $\text{Et}_2\text{O}$  solns. of equiv. amts. of the components and drying over  $\text{P}_2\text{O}_5$ , while the salts of the weaker acids were obtained only in soln. from equiv. amts. of I and the carefully dried acid in the min. quantity of the solvent in which the measurements of acidity were to be made. In the 1st measurements (with ERNST FISCHER, *Diss. Leipzig*, 1921) the red quinoid salts were produced by adding a const. amt. of I to equiv. solns. of the acid in different solvents and then the solns. were dild. with the same solvent until the color changed to red. Later, the acids in the different solvents were treated with a definite amt. of I and the concn. of acid in  $\text{H}_2\text{O}$  which gave the same shade with the same amt. of I was detd. colorimetrically. The latter is the more accurate method but does not permit of excluding moisture completely and is longer. The 1st method was, therefore, adopted with the modification that equiv. amts. of I and acid were used and the concn. at which the salt is practically completely dissoed. (as indicated by the color change) was detd. The method cannot be compared as to accuracy with the cond. method, especially for the weaker acids, but, contrary to the cond. method, its accuracy increases with in-

creasing strength of the acids and already for the strongest of the  $\text{CO}_2\text{H}$  acids is superior to the cond. method. Below are given, resp., the diln. (l. per mol.) at which the salt is completely dissoed. in  $\text{CHCl}_3$ , the ratio of this diln. to that for  $\text{AcOH}$  taken as 1, and the ratio of the dissoen. const. of the acid (detd. by Ostwald's method) to that of  $\text{AcOH}$  taken as 1:  $\text{AcOH}$  0.06, 1, 1;  $\text{ICH}_2\text{CH}_2\text{CO}_2\text{H}$  0.6, 10, 5;  $\text{HCO}_2\text{H}$  38, 633, 12;  $\text{BrCH}_2\text{CO}_2\text{H}$  63, 1050, 74;  $\text{MeCHBrCO}_2\text{H}$  64, 1067, 58;  $\text{ClCH}_2\text{CO}_2\text{H}$  70, 1167, 83;  $\text{CH}_2(\text{CO}_2\text{H})_2$  243, 4050, 87; *cis*-( $\text{CHCO}_2\text{H}$ )<sub>2</sub> 1365, 22750, 806;  $\text{N}_3\text{CS}_2\text{H}$  1450, 24160, 1290;  $\text{Br}_3\text{CCO}_2\text{H}$  3200, 53330, —;  $\text{Cl}_3\text{CCO}_2\text{H}$  5700, 95000, 10750. The strengths of the acids therefore increase in the same order as their dissoen. const. but much more rapidly and range within an interval almost 10 times greater than do the dissoen. const. This, as has repeatedly been pointed out, is due to the leveling influence of  $\text{H}_2\text{O}$  which makes the strong acids weaker by almost complete hydroxonium salt formation and makes the weak acids seem stronger. This influence of  $\text{H}_2\text{O}$  is shown by the following values for the dilns. in  $\text{CHCl}_3$ , previously shaken with  $\text{H}_2\text{O}$  and filtered, at which the I salts of the acids above are completely dissociated: 0.11, 0.8, 40, 75, 78, 65, 235, 1187, 1980, 4200. In dry  $\text{Et}_2\text{O}$ , the corresponding values are: —, — (too small to be detd.), 0.7, 2, 2, 4.5, 12, 48, 54, 70; in moist  $\text{Et}_2\text{O}$  —, —, 0.7, 2.1, 2, 4.7, 12.2, 52, 59, 80. The acidity of  $(\text{CO}_2\text{H})_2$  could not be detd. because its violet salt with I, which contains 2 mols. acid to 1 of base, is insol. in both  $\text{CHCl}_3$  and  $\text{Et}_2\text{O}$ . The same is true of  $\text{H}_2\text{SO}_4$ . Of the other strong inorg. acids, the I salts are so stable that in dry  $\text{CHCl}_3$  they are not completely dissociated in dilns up to 50,000 l. per mol. The dilns. necessary for complete dissoen. in moist  $\text{CHCl}_3$ , dry  $\text{Et}_2\text{O}$  and moist  $\text{Et}_2\text{O}$ , resp., are:  $\text{HClO}_4$  37500, 15000, 6900;  $\text{HBr}$  34100, 13900, 3000;  $\text{HCl}$  28000, 1900, 1700;  $\text{HNO}_3$  24500, 1400, 2300. To det. the acidities of the strongest acids in dry  $\text{CHCl}_3$  the more weakly basic dianisalacetone (II) was used instead of I (the violet red perchlorate and nitrate, however, do not change color on diln., and HI is oxidized and the violet color of the liberated I makes it impossible to det. the color change of the salt). The dilns. in dry  $\text{CHCl}_3$ ,  $\text{C}_6\text{H}_6$  and  $\text{PhMe}$ , resp., necessary for complete dissoen. of salts of II are:  $\text{HBr}$  29900, 7150, 7910;  $\text{HCl}$  3270, 430, 450;  $\text{Cl}_3\text{CCO}_2\text{H}$  1800, 500, 490 (in  $\text{C}_2\text{H}_2\text{Cl}_4$  1070). C. A. R.

**Aminoazobenzenes and their salts.** A. HANTZSCH and W. VOIGT. *Ber.* 62B, 968, 75 (1929).—As shown 20 yrs. ago, the aminoazobenzenes form 2 differently colored salts yellow azoid,  $\text{PhN:NC}_6\text{H}_4\text{NR}_2\cdot\text{HX}$ , and red quinoid,  $\text{PhNHN}\cdot\text{C}_6\text{H}_4\cdot\text{NR}_2\cdot\text{X}$ . On the other hand, the assumption that besides the yellow azoid salts there exist also much more strongly absorbing salts, which were, therefore, likewise considered to be quinoid, is incorrect, as already shown by Thiel, for from his extinction measurements the 1:1:0 soln. of the violet oxalate of  $\text{PhN:NC}_6\text{H}_4\text{NMe}_2$  (I) does not contain a yellow oxalate but the salt is almost completely dissociated into I and the free acid. This has been confirmed by mol. wt. detns. on more concd.  $\text{Et}_2\text{O}$  solns. of the violet but much more sol.  $\text{Cl}_3\text{CCO}_2\text{H}$  and  $\text{ClCH}_2\text{CO}_2\text{H}$  salts; the former gave values of 225.15–231.2, corresponding to 72.5–68.0% dissoen., the latter 161.1–162.4, corresponding to 98.2–96.7% dissoen. The acid is not liberated as such by the  $\text{Et}_2\text{O}$  but as an etherate,  $\text{RCO}_2\text{H}\cdot\text{OEt}_2$ ; *i. e.*, there occurs an "etherolysis." Alc. likewise produces an "alcoholysis" of the red salts. The  $\text{HCl}$  salts of  $\text{PhN:NC}_6\text{H}_4\text{NH}_2$  (II) and I in 0.0001 N soln. in abs. alc. show absorptions very similar to those of the free bases, *i. e.*, they are extensively dissoed., and only with excess of acid do they become optically const. and are then present completely as the red salts. But whereas N  $\text{HCl}$  suffices to thus convert I completely, 16 N  $\text{HCl}$  is required for II. The stronger basicity of I can only in part account for this difference, which, moreover, does not increase continuously but by steps with increasing mol. wt. of the alkyl groups on the N; the di-Et deriv. (III), because of its slight tendency to form the red salt, is again a poor indicator while the di-Pr deriv. (IV), like I, forms the red salt in smaller acid concns. This is best shown by pptg. the aminoazobenzenes from  $\text{Et}_2\text{O}$  by cautious addn. of concd.  $\text{HCl}$ ; I and III give primarily yellow salts, II and IV red salts. Because of the very slight soly. of the free aminoazobenzenes the red salts are extensively hydrolyzed by  $\text{H}_2\text{O}$ , and other so-called indifferent solvents "solvolyze" them to a greater or lesser extent, such as the  $\text{HCl}$  salt of I in  $\text{CHCl}_3$  or the acetate in  $\text{AcOH}$ . The free aminoazobenzenes also form solvates, a fact not to be neglected in using them as indicators; 0.005 N solns. of I in various solvents have the same color intensity in layers of the following depth  $\text{C}_6\text{H}_6$  7.3,  $\text{Me}_2\text{CO}$  8.5, alc. 9.8,  $\text{Et}_2\text{O}$  11.6,  $\text{CHCl}_3$  11.8, ligroin 12.4, *i. e.*, the  $\text{C}_6\text{H}_6$  solvate

analogous to those of the corresponding aminoazobenzenes. The Me ester of diethylhelianthin (see preceding abstr.), which can have only the azoid structure, has an absorption very similar to that of the yellow azoid Na salt. The unalkylated  $\text{H}_2\text{NC}_6\text{H}_4\text{N}:\text{NC}_6\text{H}_4\text{SO}_3\text{H}$ , which is yellow in solid form, shows in alc. the same absorption as  $\text{PhN}:\text{NC}_6\text{H}_4\text{NH}_2$  and therefore cannot be present in soln. unchanged as an inner salt but, at least in by far the greatest proportion, as an open aminoazobenzenesulfonic acid or, more exactly, as its ethyloxonium salt,  $\text{H}_2\text{NC}_6\text{H}_4\text{N}:\text{NC}_6\text{H}_4\text{SO}_3[\text{H}_2.\text{OEt}]$ . On the other hand, dimethyl-*o*-toluidineazobenzenesulfonic acid dissolves in alc. with yellow color as the inner azoid salt, the soln. absorbing like  $\text{PhN}:\text{NPh}$ ; even in acids it remains yellow and is only partly converted into the open benzoid salt. That the yellow and red helianthins are constitutionally different can be shown chemically by their behavior toward  $\text{N}_2\text{CHCO}_2\text{Et}$ ; only the yellow ones evolve N while the red ones react either not at all or with extraordinarily small velocity with the  $\text{N}_2\text{CHCO}_2\text{Et}$ . C. A. R.

**Esters of aminoazobenzenesulfonic acids**,  $\text{R}_2\text{NC}_6\text{H}_4\text{N}:\text{NSO}_2\text{OC}_2\text{H}_5 + 1$ . A HANTZSCH (WITH FRITZ MÜLLER). *Ber.* 62B, 966-8(1929).—It was of theoretical interest to prep. the hitherto unknown helianthin esters because they are the only constitutionally and therefore optically unchangeable derivs. of these indicators so that comparison of their absorption spectra with those of the free indicators and their salts with bases and acids should give important evidence on their constitution, concerning which there is still in part some disagreement. The Me esters, at least, can be obtained, although in very poor yield, from the free acids with  $\text{CH}_3\text{N}_2$  or from the alkali salts with  $\text{Me}_2\text{SO}_4$ . Of the helianthins which are yellow in the solid state were studied the simple amino- (I) and dimethyl-*o*-toluidineazobenzenesulfonic acid (II), of the red helianthins, monomethyl- (III), dimethyl- (IV) and diethylaminoazobenzenesulfonic acid (V). They react with very different velocities and more or less smoothly, IV the least and V best. Me ester of V (0.1 g. from 0.4 g. V allowed to stand twice 36 hrs. with  $\text{CH}_3\text{N}_2$  in  $\text{Et}_2\text{O}$ ), brick-red, m.  $125^\circ$ , difficultly sol. in alc. and  $\text{C}_6\text{H}_6$  with yellow color, not attacked by NaOH in the cold and only very slowly on heating, but easily hydrolyzed to V by HCl. Me ester of IV, decomp. about  $282^\circ$ , was obtained in such small amt. that it could be characterized only by its similarity to the ester of V in soly. and behavior toward alkalis and acids. Me ester of III, decomp.  $113^\circ$ . Me ester of II, m.  $77-8^\circ$ . I with  $\text{CH}_3\text{N}_2$  vigorously liberates N and yields chiefly IV with traces of the Me ester of the latter. The yellow and the red helianthins do not differ in principle, however, in their reactivity with  $\text{CH}_3\text{N}_2$ ; the red III and the yellow II react with about the same rapidity while the red IV reacts much more slowly and incompletely than II and III and, especially, than the likewise red V. The Me esters of III and V were also obtained by refluxing the Na salts, protected from atm. moisture, in PhMe with perfectly neutral  $\text{Me}_2\text{SO}_4$  dried with  $\text{K}_2\text{CO}_3$  and distd. *in vacuo*. C. A. R.

**The mechanism of the abnormal salt formation of pentaphenylchromium hydroxide and a unique hydrogen compound of tetraphenylchromium salts.** FR. HEIN, O. SCHWARTZKOPFF, K. HOYER, K. KLAR, W. EISSNER, W. CLAUS and W. JUST. *Ber.* 62B, 1151-67(1929); cf. C. A. 22, 2373. — The anomalous reaction of the base  $\text{Ph}_5\text{CrOH}$  with acids or salts yielding phenol and  $\text{Ph}_5\text{CrX}$  has led the authors to study its mechanism. In aq. soln. the reaction is  $\text{Ph}_5\text{CrOH} + \text{KI} + \text{H}_2\text{O} \rightarrow \text{Ph}_5\text{CrI} + \text{PhOH} + \text{KOH} + (\text{H})$ . In anhyd. solvents it is  $2\text{Ph}_5\text{CrOH} + 2\text{KI} \rightarrow 2\text{Ph}_5\text{CrI} + \text{K}_2\text{O} + \text{PhOH} + (\text{H}) + \text{Ph}$ . The facts that  $\text{Ph}_5\text{CrOPh} \cdot \text{PhOH}$  with KI yields only 2 mols. of phenol, hence proving all the Ph groups to be equally firmly held, and that even liquid  $\text{NH}_3$  yielded no aniline but only phenol lead to the conclusion that the base must first solvate, then rearrange and decomp. After much trouble the H, which nowhere made itself manifest, was finally found to be attached to the Cr of the salt in some such way as it may exist dissolved in Pd. This in no way altered any of its properties, except the spectrum. V. F. HARRINGTON

**Dialkyl-diarylelead compounds. Anti-knock studies.** HENRY GILMAN and LADISLAUS BALASSA. *Iowa State Coll. J. Sci.* 3, 105-7(1929); cf. C. A. 23, 1888.—The 4 compounds (I) dibutyl-, (II) diisobutyl-, (III) di-*sec*-butyl- and di-*tert*-butyldi-phenylead (IV) were prepd. by treating  $\text{Ph}_2\text{PbBr}_2$  with the appropriate  $\text{C}_4\text{H}_9\text{MgBr}$ . I, II and III are rather unstable yellow oils having anti-knock effects 0.33, 0.38 and 0.45 as great per mole as that of  $\text{PbEt}_4$ . IV was a solid, sol. in most org. solvents, sinters  $174^\circ$  and m.  $177^\circ$ . It is insol. in gasoline so its anti-knock effect is not accurately known. These compds. induce a malaise characteristic of volatile Pb compds. F. E. BROWN

**The bromination of 1,4-aminophenylarsonic acid.** A. LEULIER and Y. DREYFUSS. *Compt. rend.* 188, 1416-8(1929); cf. C. A. 19, 642; 22, 584. Berthelm (C. A. 4, 1299) from  $\text{H}_2\text{NC}_6\text{H}_4\text{AsO}_3\text{H}_2$  with Br in AcOH obtained in 45% yields the mono-Br deriv.

(I), and with NaOBr the di-Br deriv. (II) with some  $C_6H_5Br_2NH_2$ . L. and D. with HBr and  $H_2O_2$  obtained excellent yields of I, II and 2,4,6- $C_6H_2Br_3NH_2$  (III). I (2.80 g., almost theoretical yield), rose-white needles, does not m. 255°, was prepd. from 3 g. atoxyl in 10 cc.  $H_2O$ , 3 cc. of 48% HBr, and (added drop by drop) 2 cc.  $H_2O_2$  (100 vol.) Cryst. II (3.05 g. or 83%) was prepd. from 3 g. atoxyl, 25 cc.  $H_2O_2$  (10 vol.) and 10 cc. 92% HBr. Excess HBr (10 g.) and  $H_2O_2$  (20 cc. of 10% and 6 cc. of 50 vol.) caused the loss of all the As from atoxyl (3 g.), forming III (3.32 g.), white crystals, m. 119° (Maquenne block).

JANET D. SCOTT

**Stereoisomerism of disulfoxides and related substances.** III. Some pairs of aromatic disulfoxides. ERNEST VERRILL AND GEORGE MACDONALD BENNETT. *J. Chem. Soc.* 1928, 3189-92; cf. *C. A.* 22, 1325.—Oxidation of aromatic disulfides of the general formulas  $RSCH_2CH_2SR$  and  $C_6H_4(SR)_2$  gave in each case a pair of diastereoisomeric disulfoxides. *Dioxides of diphenylthiolethane*.— $\alpha$ , monoclinic plates or tables, m. 166° (decompn.);  $\beta$ , colorless needles with straight extinction, m. 123° (decompn.), much more sol. than  $\alpha$ . *Dioxides of di-p-tolylthiolethane*.— $\alpha$ , insol.  $H_2O$ , rhombic plates with diagonal extinction and high double refraction, m. 173-4° (decompn.),  $\beta$ , more sol. than  $\alpha$ , needles with straight extinction, m. 126-7° (decompn.). *Dioxides of dibenzylthiolethane*.— $\alpha$ , small monoclinic plates from EtOH, AmOH, 50% AcOH, flat prisms from xylene, m. 209°;  $\beta$ , feathery needles with straight extinction from xylene or AmOH, m. 192° (the disulfoxide described by Fromm, Benzinger and Schaefer (*C. A.* 7, 1001) was a mixt., m. 198°, of  $\alpha$  and  $\beta$ ). *Dioxides of 1,3-dimethylthiolbenzene*.— $\alpha$ , plates with high double refraction and straight extinction, m. 147°;  $\beta$ , rhombs with oblique extinction, m. 102° (that described by Zincke and Krueger (*C. A.* 7, 2393) was a mixt., m. 131°, of  $\alpha$  and  $\beta$ ). *Mercurichloride of 1,3-dimethylthiolbenzene*, m. 108°. *Dioxides of 1,3-dibenzylthiolbenzene*.— $\alpha$ , square plates with diagonal extinction, m. 133°;  $\beta$ , more sol., rhombic or hexagonal crystals from PhMe, characteristic spherical aggregates from  $CCl_4$ , m. 123° (the substance described by Z. and K. m. 131°). *Dioxides of 1,4-dimethylthiolbenzene*, sol. in PhMe, EtOH,  $C_6H_6$ , EtOAc and very sol. in  $H_2O$ ,  $\alpha$ , rhombic plates with oblique extinction, m. 183° (Z. and Frohneberg (*C. A.* 3, 2577) found 188°), forms a mercurichloride, silvery plates, sparingly sol.  $H_2O$ , m. 216° (decompn.);  $\beta$ , more sol. than  $\alpha$ , branching needles with oblique extinction, m. 136°, forms a mercurichloride, m. 188° (decompn.). IV. Di- and trisulfoxides of trimethylene trisulfide. *Ibid* 1929, 15-9.—Careful oxidation of pure trimethylene trisulfide by  $H_2O_2$  in  $Me_2CO$  yielded a monoxide (I), needles, m. 187°, shows a straight extinction and high double refraction and is sol. in warm  $H_2O$ , EtOH and  $Me_2CO$  but less sol. in cold  $H_2O$  or AcOH. Oxidation of I by the calcd. amt. of  $H_2O_2$  in AcOH yielded 3 cryst. substances, 2 of which were proven by direct interconversion to be polymorphs of an  $\alpha$ - or *trans*-disulfoxide (II) while the other was a distinct  $\beta$ - or *cis*-disulfoxide (III). The labile form of II, square plates, from  $H_2O$ , decomp. 220-80°, shows high double refraction and has an extinction angle of 16°. Its stable form, also from  $H_2O$ , forms stout monoclinic prisms with an extinction angle of 35°. III crystd. from  $H_2O$  in bundles of pointed needles having an extinction angle of 32° and decomp. 200-15°. Both II and III are sol. in AcOH. Further oxidation of II as before gave  $\alpha$ - or *cis*-*trans*-trimethylene trisulfoxide which crystd. from  $H_2O$  in bundles of radiating minute prisms with oblique extinction, decomp. 230-80°, and insol. in EtOH and  $Me_2CO$  but slightly sol. in AcOH and  $H_2O$ . Similar oxidation of III gave  $\beta$ - or *cis*-*cis*-trimethylene trisulfoxide, crystd. from  $H_2O$  in minute sep. prisms with an extinction angle of 32° and decomp. 220-60°, slightly sol. in EtOH,  $Me_2CO$  and other org. solvents but moderately sol. in AcOH and cold  $H_2O$ . Reduction of any of these oxides by Zn dust and HCl yielded the parent trimethylene trisulfide.

C. H. PEET

**Coupling arylsulfonanilides with diazo compounds.** M. BATTEGAY AND P. SCHNEIDER. *Chimie & industrie Special No.*, 497 (Feb., 1929).—The anilides derived from  $PhNH_2$ , *o*- and *m*-toluidine and *p*-xylylidine couple very easily in slightly alk. medium, always giving the *p*-aminoazo derivs. Coupling is not as clear nor as rapid with *p*-toluidide, the formation of the *o*-aminoazo dye being accompanied by evolution of N due to partial decompn. Asym. *m*-xylylidide gives no azo dye, but the corresponding diazoamino deriv. The behavior of these two amines when substituted in the *p*-position, leads to the supposition that *p*-substitution affects the coupling reaction, and that this position must be free in order to facilitate the formation of an azo deriv. This hypothesis was confirmed by all coupling expts. carried out on *p*-substituted anilides, particularly those that were sulfonated, the latter always giving rise to the formation of diazoamino derivs. *o*-Sulfonated *p*-toluidide, and even more so the corresponding asym. *m*-xylylidide, belong to the same group. Only the derivs. of the 2 naphthylamines regularly give aminoazo dyes.

A. PAPINEAU-COUTURE

**Action of bromine on toluenesulfonanilides.** M. BATTEGAY AND P. BESANZON. *Chimie & industrie Special No.*, 495-6 (Feb., 1929).—On the whole, 1 atom of Br is readily introduced into the mol., with formation of mono-Br derivs. Di-Br derivs. were obtained only in the case of the anilide, and tri-Br derivs. could not be obtained, the mol. apparently losing its stability and breaking down, under the action of the HBr formed, into polybrominated amine and  $p$ -MeC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>Br. Substitution of Br in the C<sub>6</sub>H<sub>5</sub> ring takes place according to the ordinary rules, being chiefly in the  $p$  position, and very little in the  $o$ -position. With  $o$ - and  $p$ -toluidides, monobromination takes place in the  $p$ - and  $o$ -positions, resp. Introduction of Br in the  $o$ -position relative to the SO<sub>2</sub>NHC<sub>6</sub>H<sub>7</sub> group decreases the stability of the bond between N and SO<sub>2</sub>. MeC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>NMeC<sub>6</sub>H<sub>7</sub> can be monobrominated at least as readily as the non-methylated compd., but the Br deriv. is much less stable and breaks down more easily in presence of excess Br. These results confirm the analogy brought out by Meyer between the SO<sub>2</sub>NHC<sub>6</sub>H<sub>7</sub> and OH groups, but shows a striking difference, since not more than 2 Br (and generally only 1) can be introduced into the mol. As Wieland (*C. A.* 16, 212) established an analogy between N<sub>2</sub>O<sub>4</sub> (to which he assigns the formula O<sub>2</sub>N.NO<sub>2</sub>) and halogens, the action of N<sub>2</sub>O<sub>4</sub> on toluenesulfonanilides was studied: primary arylsulfonanilides can form trinitro derivs. without breaking down of the mol.; secondary arylsulfonanilides offer considerable resistance to substitution and form only mononitro derivs., even in the presence of excess N<sub>2</sub>O<sub>4</sub>, but the mol. is not broken down.

A. PAPINEAU-COUTURE

**The process of reduction with esters of hydroxybenzenazoic acids.** E. PUX-EDOU. *Gazz. chim. ital.* 59, 212-8 (1929).—It would be expected that the reduction of a hydroxybenzenazoic acid would result in the formation of PhNH<sub>2</sub> and an aminohydroxy acid ester, thus:  $\text{HOC}_6\text{H}_3(\text{N}:\text{NPh})\text{CO}_2\text{R} + 2\text{H}_2 \rightarrow \text{HOC}_6\text{H}_3(\text{NH}_2)\text{CO}_2\text{R} + \text{PhNH}_2$ . However, in the expts. described in the present paper, this reaction did not take place, and instead there was cleavage or hydrolysis of the ester group, with formation of an aminohydroxy acid. A survey of the literature on the reduction of compds. similar to those used in the present expts., except for the absence of the N:NPh group, shows no such reaction except with PI<sub>3</sub> (cf. *Ann.* 133, 321), a much stronger reducing agent than the ones used by P. The anomaly in the present expts. probably depends therefore upon the influence of the N:NPh group. 2,5-HO(PhN:N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>Me (I) was prepd. by 2 different methods. (1) PhN:NCl (from 9.5 g. PhNH<sub>2</sub>, 25 cc. concd. HCl and 35 cc. of 20% NaNO<sub>2</sub>) added slowly to ice-cold  $o$ -HOC<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>Me (15 g.) in 20% KOH (125 cc.) and the product recrystd. from EtOH, yields 70-80%. (2) 2,5-HO(PhN:N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>H (20 g.) refluxed 20 hr. with MeOH (200 g.) and concd. H<sub>2</sub>SO<sub>4</sub> (20 g.), cooled and the product recrystd. from EtOH gives a lower yield. Reduction was carried out with PhHNNH<sub>2</sub> (II) in the general way described in earlier expts. (cf. *Gazz. chim. ital.* 36, ii, 305 (1906); 37, i, 68 (1907)). I (12 g.) and II (12 g.) heated to 120°, let cool to 100° during several min. and reheated to 120° several times, the solidified mass washed with EtOH, and the residue recrystd. from water, yields 0.5-0.7 g. of 2,5-HO(H<sub>2</sub>N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>H (III). No 2,5-HO(H<sub>2</sub>N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>Me (IV) could be detected. Reduced with Sn and HCl in the ordinary way and the 2 HCl salts obtained as products decompd. by NaHCO<sub>3</sub>, II yields III (1.8-2.0 g. from 5 g. of II), while no IV could be detected. 2,5-HO(PhN:N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>Et (V) was prepd. by the same 2 methods used for I. Reduced with II, it yields III, the yield being lower than from I. Reduction with Sn and HCl gave a higher yield than did II. I (5 g.) in 20% KOH (50 cc.) agitated vigorously with Me<sub>2</sub>SO<sub>4</sub> (10 g.) and the ppt. recrystd. from EtOH, yields the *Me ether* of I, 2,5-MeO(PhN:N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>H, red-yellow, m. 66°, insol. in cold aq. alk. hydroxides. A better yield is obtained if Me<sub>2</sub>SO<sub>4</sub> is replaced by a mixt. of MeI and MeONa. In a similar way from V and Me<sub>2</sub>SO<sub>4</sub> or a mixt. of MeI and NaOMe was prepd. the *Me ether* of V, m. 64°, the yield being low. Following the usual procedure for coupling diazonium salts, 2,5-HO(PhN:N)C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>Ph (in cold KOH) forms 2-hydroxyazo derivs., a monoazo compd. which ppts. and a disazo compd. which remains in alk. soln. This soln. acidified and the ppt. recrystd. from EtOH yields *Ph benzenedisazoaldehyde* (VI), reddish yellow, m. 149°. VI (5 g.) reduced with II (12 g.), the product washed with Et<sub>2</sub>O and purified from water, yields 2,3,5-HO(H<sub>2</sub>N)<sub>3</sub>C<sub>6</sub>H<sub>2</sub>CO<sub>2</sub>H.

C. C. DAVIS

**Photochemical transformation of  $o$ -nitrobenzaldehyde.** RUDOLF WEGSCHEIDER. *Monatsh.* 52, 68-72 (1929).—The expts. of Weigert and Brodman (*Z. phys. Chem.* 120, 24 (1926); cf. *C. A.* 20, 547) on the photochem. transformation of  $o$ -O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO in Me<sub>2</sub>CO are not consistent with the supposition that exactly 2 quanta are assocd. with 1 mol. of the end product,  $o$ -ONC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H. The differences between the calcd. and observed values may be explained by assuming a spontaneous inactivation of the

activated mol. in  $\text{Me}_2\text{CO}$ ; this supposition also explains the peculiar behavior of the solid aldehyde observed by Bowen, Hartley, Scott and Watts (C. A. 18, 3548).

C. J. WEST

**A comparative study of methyl- and ethylprotocatechualdehyde.** LVELL KLOTZ. *Am. J. Pharm.* 101, 442-7 (1929).—A comparison of color reactions of the 2 compds. showed that vanillin and ethylvanillin exhibit marked similarity in every instance. Results show that the reactions are due to either the HO or the CHO groups in every case. Substituted groups in the *m*-position have little or no effect on the color reactions of the homologs of vanillin. Reasons for the color changes of these compds. are interpreted according to the theories of Witt and Lewis.

W. G. GAESSLER

**The displacement of the aldehyde group in piperonal and its derivatives.** ALBERT H. PARIJS. *Thesis, Leiden, 1928*, 194 pp.—The displacement of CHO and  $\text{CO}_2\text{H}$  groups by  $\text{NO}_2$ , Cl and Br groups as shown by the literature is reviewed for hydroxybenzene, hydroxynaphthalene and pyrrole derivs. Nitration of 25 g of piperonal yielded 5 g. of 6,3,4- $\text{O}_2\text{N}(\text{CH}_2\text{O})_2\text{C}_6\text{H}_2\text{CHO}$  (I), m. 147°, and 26.4 g. of 1,2,4- $\text{C}_6\text{H}_3(\text{NO}_2)(\text{O}_2\text{CH}_2)$ , m. 95.5° (II). Derivs. of I prep'd. were the diacetate, m. 142°, with  $\text{Ac}_2\text{O}$ ; 6,6'-dinitro-3,4,3',4'-bis[methylenedioxy]benzalazine, m. 257° (decompn.), with  $\text{N}_2\text{H}_4$ ; phenylhydrazone, m. 218.5° (decompn.); *p*-nitrophenylhydrazone, m. 245° (decompn.); semicarbazone, m. 272.5-278° (decompn.);  $\text{NH}_2\text{NHCOCONH}_2$  deriv., m. 325° (decompn.); 5 g. of I on nitration yielded 4.5 g. of 4,5,1,2- $\text{C}_6\text{H}_2(\text{NO}_2)_2(\text{O}_2\text{CH}_2)$  (III), m. 100°. Treatment of III with  $\text{NH}_3$  or amines yielded products in which a  $\text{NO}_2$  group was substituted. The following 4-nitropyrocatechol methylene ethers were prep'd.: 5-amino, m. 196-7°; 5-methylamino, m. 171°; 5-ethylamino, m. 133°; 5-propylamino, m. 115°; 5-butylamino, m. 137°; 5-amylamino, m. 95°; 5-heptylamino, m. 79°; 5-dimethylamino, m. 98°. 1 g. III in MeOH treated with 0.566 g.  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  yielded 6,6'-dinitro-3,4,3',4'-dimethylenetetraxydiphenyl sulfide, m. 234°, transition temp. 215-220° to an orange form.  $\text{Na}_2\text{S}_2$  with III yielded a disulfide, m. 266°. Piperonal (25 g.) on chlorination yielded 19 g. 6-chloropiperonal (IV), m. 115°, and 2.5 g. of 4,5-dichloropyrocatechol methylene ether, m. 82°. The derivs. of IV prep'd. were the following: diacetate, m. 133°; benzalazine, m. 303° (decompn.); phenylhydrazone, m. 117-8°; *p*-nitrophenylhydrazone, m. 281-2° (decompn.); semicarbazone, m. 280° (decompn.); semioxamazone, m. 299° (decompn.); 8 g. of IV on nitration yields 7 g. of 4-nitro-5-chloropyrocatechol methylene ether, m. 70°, which on reduction yields an amine, m. 254-5° (decompn.). IV on treatment with amines yields the same compds. as III: treatment with  $\text{Na}_2\text{S}$  or  $\text{Na}_2\text{S}_2$  yields the same disulfide as obtained with  $\text{Na}_2\text{S}_2$  on III. Bromination of 50 g. of piperonal yielded 28.5 g. of 6-bromopiperonal (V), m. 129°, and 4.5 g. of 4,5-dibromopyrocatechol methylene ether, m. 85°. Derivs. of V prep'd. were: diacetate, m. 128°; benzalazine, m. 249-52° (decompn.); *p*-nitrophenylhydrazone, m. 253° (decompn.); semicarbazone, m. 230° (decompn.); semioxamazone, m. 278.9° (decompn.). Nitration of 3 g. of V yielded 3 g. of 4-nitro-5-bromopyrocatechol methylene ether (VI), m. 89°.  $\text{Na}_2\text{S}$  and  $\text{Na}_2\text{S}_2$  with V yielded the same diphenyl disulfide as III and IV. Nitration of 4 g. of VI yielded 4.5 g. of 3,4-dinitro-5-bromopyrocatechol methylene ether, m. 172°. VII with alc.  $\text{MeNH}_2$  gives 35% of 3-nitro-1-methylamino-5-bromopyrocatechol methylene ether, m. 67° (decompn.). Treatment of 4 g. of the diacetate of II with  $\text{HNO}_3$  at a low temp. opens the  $\text{CH}_2\text{O}_2$  ring and yields 2.5 g. of 6,3,4- $\text{O}_2\text{N}(\text{HO})_2\text{C}_6\text{H}_2\text{CHO}$  (VIII), m. 203° (decompn.). Derivs. of VIII prep'd. were: benzalazine, m. 278° (decompn.); semicarbazone, m. 254° (decompn.); phenylhydrazone, m. 203° (decompn.); *p*-nitrophenylhydrazone, m. 290° (decompn.). Three g. of V with  $\text{HNO}_3$  yielded 2 g. of 6,3,4-Br(HO) $_2\text{C}_6\text{H}_2\text{CHO}$  (IX), m. 220°. Derivs. of IX prep'd. were: benzalazine, m. 251° (decompn.); semicarbazone, m. 239°; *p*-nitrophenylhydrazone, m. 243° (decompn.). Fifteen g. of piperonal treated with 2.5 g. of Na in abs. MeOH yielded 3.5 g. of piperonyl alc. and 5 g. of piperonylic acid. The MeONa in this reaction behaves as NaOH in the Cannizzaro reaction. 1.5 g. of III treated with 0.15 g. Na in abs. MeOH yields 1 g. of 4,5-dinitropyrocatechol, m. 177°. III with EtONa yielded 2,4,5-EtO( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_2\text{OH}$ , m. 113°. Nitration of *o*- $\text{C}_6\text{H}_4(\text{OMe})_2$  gave quantitatively 4-nitroveratrole, m. 96°, which on further nitration gave 90% of 4,5-dinitroveratrole (X), m. 131°. One g. of X with 0.65 cc.  $\text{NH}_3$  (d. 0.91) in 6 cc. MeOH yields 0.6 g. 4-nitro-5-amino-1,2-dimethoxybenzene (XI), m. 175°. XI yields an Ac deriv., m. 198.5°. Other amines used to replace one of the  $\text{NO}_2$  groups of X yielded the following homologs: 5-methylamino, m. 146°; 5-ethylamino, m. 174-5°; 5-propylamino, m. 141-2°; 5-butylamino, m. 114°; 5-amylamino, m. 130-1°. Two  $\text{C}_6\text{H}_3(\text{NO}_2)(\text{OMe})_2$  and 2,4,5-trinitro-1,2-dimethoxybenzene yielded 6,6'-diphenylsulfide, m. 220-220.5°, while the corresponding disulfide, m. 212° (decompn.)

is obtained with  $\text{Na}_2\text{S}_2$ . The reaction velocities of the action of  $\text{NaOMe}$  on dinitro compds., represented by the reaction,  $\text{XNO}_2 + \text{MeONa} = \text{XOMe} + \text{NaNO}_2$ , was studied for *p*-(XII), and *o*- $\text{C}_6\text{H}_4(\text{NO}_2)_2$  (XIII), and X.  $K_{25}$  (reaction velocity const.) for XII was found to be 0.0219, checking Steger's value of 0.0221. For XIII,  $K_{25} = 0.0242$ ,  $K_{45} = 0.069$ ; for X,  $K_{25} = 0.0029$ ,  $K_{45} = 0.0088$ . ARTHUR FLEISCHER

**Alkalines. II. Formation of secondary amino alcohols from aldioximes. I.** S. KANAO. *J. Pharm. Soc. Japan* 49, 157-70(1929); Abstract sect. 26-32.—In order to obtain secondary bases from primary amino alcs. for studying the relation of structure to physiol. action of alkalines, nitro alcs. were reduced to hydroxyamino alcs., and the latter were converted into aldioximes by means of aldehydes. By reducing the aldioximes with Zn and  $\text{AcOH}$ , the desired amino alcs. were obtained. This method of reduction is of value in the reduction of compds. where alk. reduction cannot be used, i. e., as in the case of 34-( $\text{HO}$ ) $\text{C}_6\text{H}_4\text{CH}_2$  derivs. Most of the aldioximes thus obtained were cryst. but they were generally unstable, especially enanth- and citraldioximes. By boiling with dil. mineral acids they decomp. into the corresponding hydroxylamine and aldehyde. Aliphatic aldioximes were more easily reduced than aromatic aldioximes. Alkylated secondary bases of the phenylpropanol series and their oxalates were obtained in good cryst. form, but their  $\text{HCl}$  salts, chloroaurates and chloroplatinates could not be crystd., while most of the alkylated secondary bases and their salts were obtained in good cryst. form. Reduction of  $\text{PhCH}(\text{OH})\text{CH}(\text{NO}_2)\text{Me}$  (I) with Zn and  $\text{AcOH}$  gave  $\text{PhCH}(\text{OH})\text{CH}(\text{NHOH})\text{Me}$  (II), m. 78-9° (yield 60%). Bz deriv., m. 180-1°. II and  $\text{HCHO}$  gave 1-phenyl-2-[methylenecoximino]-1-propanol (III), m. 139°. By catg. the residue of the mother liquor of III with  $\text{C}_6\text{H}_6$ -petroleum ether mixt. the isomer of III, m. 106°, was obtained. Further reduction of I with Zn and  $\text{AcOH}$  in presence of  $\text{MeCHO}$  and  $\text{CuSO}_4$  gave 1-phenyl-2-ethylamino-1-propanol, m. 86° (isolated as the oxalate, decomp. 223°). I,  $\text{Me}_2\text{CHCH}_2\text{CHO}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-[isomethylideneoximino]-1-propanol (IV), m. 128°. Further reduction of IV with the aid of  $\text{CuSO}_4$  gave 1-phenyl-2-isomethylamino-1-propanol, b<sub>18</sub> 176°, m. about 50-60° (isolated as  $\text{HCl}$  salt, m. 209-10° (decompn.)). I,  $\text{Me}(\text{CH}_2)_2\text{CHO}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-[methylideneoximino]-1-propanol (V), m. 119°. Further reduction with the aid of  $\text{CuSO}_4$  gave 1-phenyl-2-heptylamino-1-propanol (VI), m. 67° (isolated as the  $\text{HCl}$  salt, m. 229°). From the mother liquor of VI, the isomer of VI was isolated as its  $\text{HCl}$  salt, m. 189°. Oxalate, m. 217-8° (decompn.). Chloroaurate, m. 169° (decompn.). I,  $\text{BzH}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-[benzylideneoximino]-1-propanol (VII), m. 140°. Further reduction gave 1-phenyl-2-benzylamino-1-propanol, m. 99° (isolated as the oxalate, m. 193°). I, *o*- $\text{HOCH}_2\text{H}_2\text{CHO}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-[*o*-hydroxybenzylideneoximino]-1-propanol (VIII) which on further reduction with the same reagents gave the corresponding hydroxybenzylamino compd., m. 117.5°. Oxalate, m. 172° (decompn.); bioxalate, contains 2.5 mols  $\text{H}_2\text{O}$  of crystn. and m. 83° (anhyd., m. 110°). Cu compd., m. 220° (decompn.). I, 2,3- $\text{HO}(\text{MeO})\text{C}_6\text{H}_3\text{CHO}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-*o*-vanillylamino-1-propanol, m. 127°. Oxalate, softens 85°, m. 149° (decompn.). Cu compd., m. 166° (decompn.). I, 3,4- $\text{MeO}(\text{HO})\text{C}_6\text{H}_3\text{CHO}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-[vanillylideneoximino]-1-propanol, m. 123-4°. Further reduction gave the corresponding vanillylamino compd., m. 144°. Oxalate, m. 197°. I,  $\text{CH}_2\text{O}_2$ - $\text{C}_6\text{H}_4\text{CHO}$ , Zn and  $\text{AcOH}$  gave 1-phenyl-2-[piperonylideneoximino]-1-propanol, m. 138°. Further reduction gave the piperonylamino deriv., m. 85.5° (isolated as the oxalate, m. 206° (decompn.)). 1-Phenyl-2-[3,4-dihydroxybenzylideneoximino]-1-propanol, m. 203° (decompn.) (from I and 3,4-( $\text{HO}$ ) $\text{C}_6\text{H}_3\text{CHO}$ ). 3,4-Dihydroxybenzylamino compd., m. 171° (decompn.). 1-Phenyl-2-[furfurylideneoximino]-1-propanol (IX), m. 150° (from I and  $\text{C}_6\text{H}_5\text{OCHO}$ ). From the mother liquor of IX the isomer of IX, m. 116°, was isolated. Furfurylamino deriv. of IX (X), m. 87°. Oxalate, m. 194.5°. The isomer of X, m. 188° (decompn.). 1-Phenyl-2-[citrylideneoximino]-1-propanol (XI), m. 155-6° (from I and  $\text{Me}_2\text{C}:\text{CH}(\text{CH}_2)_2\text{CMeC}:\text{CHCHO}$ ). Isomer of XI, m. 128°. The  $\text{HCl}$  salt of the citrylamino compd. of XI has a strong local anaesthetic action. N. U.

A homolog of ephedrine. J. SAEM DE BURNAGA SANCHEZ. *Bull. soc. chim.* [4], 45, 284-6(1929).—*p*-Tolyl- $\alpha$ -methylaminoethylcarbinol (methylephedrine) was prepd. and its physiol. properties studied (cf. Adams, C. A. 22, 3154). The *p*-methylephedrine has a weaker hypertensive action than ephedrine. WALLACE R. BRODE

Condensation of aromatic aldehydes with glycine and acetylglycine. H. D. DAKIN. *J. Biol. Chem.* 82, 439-46(1929).—The condensation referred to in the title is complicated by a competing reaction between  $\text{CH}_2(\text{NH}_2)\text{CO}_2\text{H}$  and  $\text{BzH}$ , forming a non-acetylated deriv. possibly of a type resembling a Schiff base. The 2 reactions are shown thus: (1)  $\text{H}_2\text{NCH}_2\text{CO}_2\text{H} \rightarrow \text{AcNHCH}_2\text{CO}_2\text{H} \rightarrow \text{MeC}:\text{N}:\text{C}:(\text{CHPh})\text{CO}_2\text{H}$

→ MeCONHC(:CHPh)CO<sub>2</sub>H. (2) HO<sub>2</sub>CCH<sub>2</sub>NH<sub>2</sub> + BzH → HO<sub>2</sub>CCH<sub>2</sub>NHCHPh (I) or O.CO.CH<sub>2</sub>.NH.CHPh. I may be called benzylideneglycine and was

isolated and analyzed. Because the 2nd condensation product is a non-acetylated compd. its formation can be largely suppressed by acetylating the glycine before the reaction. Correspondingly larger yields of the azlactone of α-acetamidocinnamic acid were obtained. Acetylation was most easily effected by warming glycine suspended in 3 parts of glacial AcOH with the theoretical amt. of Ac<sub>2</sub>O until soln. was obtained. A variety of aldehydes was used although the product from salicyl aldehyde was the most interesting. AcOC<sub>6</sub>H<sub>4</sub>CH:C.N:CMc.O.CO (II) → HOC<sub>6</sub>H<sub>4</sub>

CH:C(NHAc)CO<sub>2</sub>H (III). - O.C<sub>6</sub>H<sub>4</sub>.CH:C(NHAc).CO (IV). II on treating with

alkali and subsequent acidification forms the transient III which quickly passes over to IV. Detailed exptl. data are given.

**cis-trans-Isomerism and steric hindrance.** VIII. Monomethyl *o*-hexahydrophthalates. G. VAVON AND P. PEIGNIER. *Bull. soc. chim.* 45, 299-302(1929).—The *cis*- (I) and *trans*-mono-Me *o*-hexahydrophthalates (II) were prepd. Esterification of I with MeOH goes 1.4 times slower than that of II. Sapon. of I goes 5-10 times slower than that of II.

**Hexahydro-*o*-phthalic acids.** G. VAVON AND P. PEIGNIER. *Bull. soc. chim.* 45, 293-9(1929).—Hydrogenation of mono-Me *o*-phthalate with Pt black as catalyst gives *cis*-hexahydrophthalate (I). The *l*-rotatory isomer of I (m. 148-9°, [α]<sub>D</sub><sup>20</sup> 6.67°, *c* 0.1 in EtOH) gives on sapon. an inactive acid. The *l*-rotatory *cis*-hexahydrophthalamide ([α]<sub>D</sub><sup>20</sup> -15.4°, *c* 0.02 in EtOH), isolated by means of the quinine salt, gives on heating an inactive imide.

**Configuration determinations in the terpene series.** II. The optically active forms of β-isopropyladipic acid and their relation to the optically active limonenes. JULIUS V. BRAUN AND GEORG WERNER. *Ber.* 62B, 1050-8(1929); cf. *C. A.* 20, 2990.—It was shown in the 1st paper that the configuration of the C atom carrying the Me group in the natural *d*-rotatory citronellal, the *d*-rotatory citronellol, pulegone, the *d*-rotatory menthone and *l*-rotatory menthol is the same and corresponds to that of the *d*-rotatory pyrotartaric (I) and of the *d*-rotatory β-methyladipic acid (II) when the formulas of these compds. are so written that the valence to the O-contg. part of the mol. (or the nearer CO<sub>2</sub>H group in the case of II) of the asym. C atom corresponds to that through which in I the CO<sub>2</sub>H group is held. This was shown by establishing the genetic relationship between I and the II which is obtained by the oxidative degradation of some of these compds. It is probable, although not definitely proved, that this configuration corresponds to that of *d*-tartaric acid and the prefix *d*- is accordingly used for the Me-carrying C atom in this series of compds. These results gave rise to the desire to det. whether there is a similar simple relationship as regards another asym. C atom often occurring in this class of compds., viz., the C atom, usually in the 4-, more rarely in the 3-position to the CHMe group, carrying the iso-Pr or isopropenyl residue, and which either alone (as in limonene, carvone, diosphenol, silvestrene) or together with the CHMe group (as in menthone) conditions the optical activity. It is known that in some cases this C atom can be oxidized out as isopropylsuccinic acid and in others as β-isopropyladipic acid (III). Here, however, the problem was much more difficult, for there were in general no exact data in the literature on the optical activity of the 2 expected iso-Pr-contg. di-CO<sub>2</sub>H acids, on the *d*- and *l*-forms prepd. artificially by resolution of the *dl*-forms and, naturally, on the genetic relationship between the tartaric acids and these acids; finally, the inactive III is extraordinarily difficultly available. The 1st problem attacked, therefore, was that of prep. III in sufficient quantities. A repetition of Blanc's work convinced v. B. and W. that this method would not be practical but the fact that *p*-methylcyclohexanol readily yields II on oxidation suggested the use of *p*-isopropylcyclohexanol (IV) as the starting material. *p*-iso-PrC<sub>6</sub>H<sub>4</sub>OH was readily hydrogenated with Ni at 150° to IV and this, after some experimenting to det. the proper conditions, was converted with satisfactory yield into III which by means of strychnine was resolved into the *d*-rotatory form with max. rotation and the *l*-rotatory form with not quite a const. final rotation. To oxidize the optically active 4-C atom out of limonene the 8,9-double bond naturally had first to be eliminated. This, it was found, could not be effected by adding HCl, for extensive racemization occurred in the process and by varying the length of the HCl treatment hydrochlorolimonenes with widely different rotations could be obtained. On the other hand, the dihydrolimonene (V) obtained by hydrogenation of pure *d*-rotatory

limonene with  $H_2$  and Pt gave an optically active *ketoaldehyde* (VI) and *keto acid* (VII) and the latter finally yielded a *III* with the same rotation as that obtained by resolution of the *dl*-form. On the very probable assumption that, like the *d*-rotatory II, it belongs to the *d*-series, the *d*-rotatory hydrocarbon would then be represented by the symbol *d*(+)-limonene. *dl*-III, obtained in 50% yield from IV (in not more than 10 g. portions) shaken 8–10 hrs. below  $10^\circ$  with 3 parts  $KMnO_4$  and 0.5 part KOH in not quite 100 parts  $H_2O$ ,  $b_{12}$  215–8°, m.  $75^\circ$ ; *di-Ester*,  $b_{12}$  145–50°,  $d_4^{20}$  0.9776. *Strychnine salt* of (+)-acid, m.  $182^\circ$ ; *Na salt*,  $[\alpha]_D^{20}$  5.4°; free acid, m.  $66^\circ$ . (–)-Acid, m. around  $60^\circ$ ; *Na salt*,  $[\alpha]_D^{20}$  –4.1°. *Chloride* of the (+)-acid, prepd. with cold  $SOCl_2$ ,  $b_{12}$  145–6°,  $d_4^{20}$  1.1023,  $[\alpha]_D^{20}$  1.134°; *amide*, m.  $169.5^\circ$ ,  $[\alpha]_D^{20}$  9.5° (2.22% aq. soln.); *Et ester*, prepd. with HCl and alc.,  $b_{12}$  145–50°,  $d_4^{20}$  0.9776,  $[\alpha]_D^{20}$  –1.534° (no solvent). With HCl very carefully dried with  $H_2SO_4$  and  $P_2O_5$  v. B. and W. obtained, after satg. limonene in  $CS_2$  for 6 hrs., an analytically pure HCl addn. product,  $b_{12}$  100–1°, with  $[\alpha]_D^{20}$  75.8°; after 8 hrs.  $[\alpha]_D^{20}$  was  $54^\circ$ , after 24 hrs. treatment with a current of HCl, standing another 2 days under HCl pressure and again treating 5 hrs. with HCl it was  $33^\circ$ . The V,  $[\alpha]_{578}^{20}$  118°, was obtained by Vavon's method (Pd, either on charcoal or colloidal in gum arabic, instead of Pt gave a mixt. of unchanged limonene and the di- and tetrahydro derivs.). VI, from V and 3%  $O_3$  in 4 parts AcOH (yield, more than 60%),  $b_{12}$  130–2°,  $d_4^{20}$  0.9393,  $[\alpha]_D^{20}$  –6.97°; *semicarbazone*, m.  $182-3^\circ$ . VII, from VI and cold aq.  $KMnO_4$  (somewhat more than 1 atom O; yield, 75%), thick yellowish oil,  $b_{12}$  188°,  $d_4^{20}$  1.020,  $[\alpha]_D^{20}$  2.5°, gives (+)-III with ice-cold NaOBr (6 atoms Br). C. A. R.

**Some physical properties of nitrophenols.** LOUIS DEVERGNE. *Rev. chim. ind.* 38, 66–9(1929); cf. C. A. 21, 3607.—2,4,6-Trinitro-*m*-cresol recrystd. from  $C_6H_5.HNO_3$  and washed with EtOH and  $CHCl_3$ , m.  $106.47^\circ$ ; soly. in  $H_2O$  at  $17.5^\circ$  0.2372, at  $50^\circ$  0.5662, at  $100^\circ$  2.165; soly. (at  $17^\circ$  and  $50^\circ$ ) in AcOEt 37.269, 76.52;  $Me_2CO$  94.810, 197.43; MeOH 11.772, 43.15; 96% EtOH 5.535, 18.05; abs. alc. 6.174, 18.53;  $C_6H_6$  13.497, 56.10;  $CHCl_3$  3.568, 15.67;  $C_6H_5N$  11.608, 25.15;  $CCl_4$  0.173, 1.08;  $C_7H_8$  14.404, 47.50; anhyd.  $Et_2O$  4.423 at  $17^\circ$ , 6.81 at  $34^\circ$ ;  $CS_2$  0.078 at  $17^\circ$ , 0.34 at  $36^\circ$ ; in contact with  $C_6H_5N$  there is a slight rise in temp. with formation of canary-yellow crystals, m.  $112-3^\circ$ , slightly sol. in  $H_2O$  and EtOH, insol. in cold  $C_6H_6$  and almost insol. in boiling  $C_6H_6$ ; the analysis corresponds with the formula  $2,4,6-(O_2N)_3C_6H(OH)Me$ .— $C_6H_5N$ . 3,5-Dinitroanisole, prepd. by the action of MeONa on 1,3,5- $(O_2N)_3C_6H_3$ , m.  $104.7^\circ$ ; recrystd. from  $HNO_3$  and washed it solidifies (3 detns.) at  $105.48^\circ$ ,  $105.50^\circ$ ; soly. in  $H_2O$  at  $25^\circ$  0.003, at  $50^\circ$  0.006, at  $100^\circ$  0.182, no trace of sapon. after 1 hr. boiling; soly. (at  $20^\circ$ ) in AcOEt 11.132,  $Me_2CO$  22.333; 96% EtOH 0.563; abs. alc. 0.705, MeOH 1.193;  $C_6H_6$  10.404;  $CHCl_3$  14.836; anhyd.  $Et_2O$  2.988;  $C_6H_5N$  18.850;  $CS_2$  0.728;  $CCl_4$  0.728;  $C_7H_8$  10.540. 2,3,5-Trinitroanisole recrystd. from  $HNO_3$ , washed with EtOH, solidifies at  $106.80^\circ$ ; soly. in  $H_2O$  at  $18^\circ$  (48 hrs.) 0.011; at  $50^\circ$  (24 hrs.) 0.052; at  $100^\circ$  (30 min.) 0.278; the  $H_2O$  soln. is yellow due to the splitting of MeOH and formation of  $(O_2N)_3C_6H_2OH$ ; soly. at  $25^\circ$ : AcOEt 47.756;  $Me_2CO$  135.385; 96% alc. EtOH 2.341; abs. alc. 2.571; MeOH 5.533;  $C_6H_6$  18.036;  $CHCl_3$  3.618; anhyd.  $Et_2O$  3.478;  $C_6H_5N$  20.398;  $CS_2$  0.297;  $CCl_4$  0.268;  $C_7H_8$  20.582; with  $C_6H_5N$  it gives an intense red color with rise of temp., then a ppt.; this is partly sol. in  $H_2O$  with deep orange color. 2,3,5,6-Tetranitroanisole gives white crystals when recrystd. from  $HNO_3$ , it solidifies at (3 detns.)  $153^\circ$ ,  $153.5^\circ$ ,  $153.5^\circ$ ; soly. in  $H_2O$  at  $27^\circ$  (48 hrs.) 0.0075; at  $50^\circ$  (24 hrs.) 0.022; at  $100^\circ$  (1 hr.) 0.139; the water soln. is colored due to splitting of MeNO<sub>2</sub> and formation of  $(O_2N)_3C_6H_2OH$ ; soly. at  $29^\circ$ : AcOEt 37.001;  $Me_2CO$  101.148; 96% EtOH 1.875; abs. alc. 2.376; MeOH 4.394;  $C_6H_6$  1.551;  $CHCl_3$  0.787; anhyd.  $Et_2O$  1.656;  $CS_2$  0.077;  $CCl_4$  0.068;  $C_7H_8$  1.019, a slight sapon. takes place with MeOH, EtOH and  $Me_2CO$  and the soln. is canary yellow. With  $C_6H_5N$  a deep red soln. results with strong evolution of N oxides; after evapn. of  $C_6H_5N$  a blood-red residue, sol. in 95% alc. and somewhat in  $H_2O$ , is left.

P. THOMASSET

**Formation and cleavage of glucosides as a method for the chemical and biochemical separation of racemic alcohols into their optically active forms.** C. NEUBERG, K. P. JACOBSON AND J. WAGNER. *Fermentforschung* 10, 491–531(1929).—A new method for the resolution of *dl*-alcs. into their optically active components consists in the prepn. of glucosides and sepn. of these by crystn. In the formation of glucosides between an individual glucose, e. g., the  $\alpha$ - or  $\beta$ -form of *d*-glucose, and the *dl*-alc., the *d*-alkyl *d*-glucoside and the *l*-alkyl *d*-glucoside are not enantiomorphs, but diastereomers with different velocities of formation. This is easily demonstrated by the optical activity of the unreacted alc. remaining when the glucosidification is interrupted before completion. The condensation is performed by treatment of the *dl*-alc. in  $Et_2O$  with

acetobromoglucose in the presence of  $\text{Ag}_2\text{CO}_3$  or quinoline as a condensing agent. Contrary to the prevalent notion, a large excess of the alc. is not necessary. It is thus possible to effect a sepn. into an optically active residual alc. and a glucoside containing the optical isomer which may be recovered by non-specific hydrolysis. This sepn. was demonstrated in the case of *dl*-borneol and *dl*-menthol.  $\text{Ag}_2\text{CO}_3$  leads to formation of  $\beta$ -glucosides, while the quinoline condensation gives both  $\alpha$ - and  $\beta$ -glucosides. In the latter instance the distribution of alc. between  $\alpha$ - and  $\beta$ -glucose is specific. With *dl*-menthol the *d*-form yields a  $\beta$ -glucoside and the *l*-form an  $\alpha$ -glucoside. The  $\beta$ -glucoside thus obtained underwent 100% cleavage by emulsin from almonds, the  $\alpha$ -glucoside 100% cleavage by  $\alpha$ -glucosidase (maltase) from yeast, but with mixts. the reverse order no cleavage occurred. The sepn. of the *dl*-alc. component was not a matter of fractional crystn. After crystg. out the *d*-menthyl  $\beta$ -glucoside tetraacetate the mother liquor yielded the *l*-menthyl  $\alpha$ -glucoside, but no further glucoside was present in the 2nd mother liquor. In other words, the fractionation that would have been required for resolution of a partially racemic mixt. was not employed. The actual resolution had occurred during the process of glucoside formation. With  $\text{Ag}_2\text{CO}_3$ , *dl*-PrMeCHOH formed only the partially racemic glucoside, the resolution of which required continued fractionation. Neither the unreacted alc. recovered by steam distn. nor the alc. obtained by acid hydrolysis of the glucoside was optically active. The racemic mixt. obtained by mixing equal parts of *d*-bornyl  $\beta$ -glucoside and *l*-bornyl  $\beta$ -glucoside can be sepd. by fractional crystn. so that one fraction when hydrolyzed by mineral acid yields *d*-borneol and the other *l*-borneol. The tetraacetate of *dl*-menthyl  $\beta$ -*d*-glucoside can be resolved in this manner, but the sepn. of the free *dl*-menthyl  $\beta$ -*d*-glucoside into its isomers was unsuccessful. Both *dl*-amyl glucoside and its tetra-Ac deriv. may be resolved by fractional crystn. In the biochem. cleavage of the  $\beta$ -glucosides by the appropriate enzyme the *d*- and *l*-alcs. are split off at different rates. Hydrolysis by emulsin yields first *d*-, then *l*-menthol, first *l*-, then *d*-borneol first *l*-, then *d*-PrMeCHOH.

A. W. DOX

**Camphoroglucuronic acid and synthesis of hydroxycamphor glucoside.** M. ISHIDA. *J. Pharm. Soc. Japan* **49**, 336-46 (1929).—On the basis of the previous work by Asahina and I. (C. A. **22**, 2161, 3406), *d*-camphor (I) in the animal body is considered to take the following route. I is first oxidized mostly to *p*(5)-hydroxycamphor (II) and partly to *o*( $\alpha$ )-hydroxycamphor (III). II and III then combine with glucose and form *p*- and *o*-hydroxycamphor glucoside (IV and V) and are finally eliminated in the urine as *p*- and *o*-hydroxycamphoroglucuronic acids (VI and VII), resp. In order to det. whether Schmiedeberg and Meyer's (*Z. physiol. Chem.* **3**, 422) *d*-camphoroglucuronic acid (m. 128-30°) and Magnus-Levy's (*C. A.* **1**, 877) *p*-hydroxycamphoroglucuronic acid (m. 120-30°) have the same structure represented by either IV or V, the glucuronic acid mixt. was prepd. according to L.'s method. By purification with strychnine, only one kind of *cryst. salt*, m. 190-5°, was obtained. The free acid proved to be VI, m. 138°,  $[\alpha]_D^{15}$  -23.08° (anhyd.), m. 130° (hydrated). Neither the strychnine salt of VII nor the free acid could be crystd. They were detected in small amt. in the mother liquor from VI. Contrary to the statement by S. and M., VI and mentholglucuronic acid could be hydrolyzed by means of emulsin if the proper conditions were maintained, i. e., in the presence of a buffer, at  $p_H$  5-6 and 35°. Syntheses of IV and V and another glucoside having Manasse's  $\beta$ -hydroxycamphor (VIII) (*Ber.* **35**, 3816) as its aglycone were accomplished. II, from camphorol, acetobromoglucose and  $\text{Ag}_2\text{CO}_3$  in Et<sub>2</sub>O (Fischer's method) gave tetraacetyl-*p*-hydroxycamphor glucoside (IX), softens 142-3°, m. 147-8°,  $[\alpha]_D^{17.5}$  -11.7° (in C<sub>6</sub>H<sub>6</sub>). Oxime, m. 135-6°. Hydrolysis of IX with Ba(OH)<sub>2</sub> in dil. EtOH gave IV, which could not be crystd. except in a desiccator under reduced pressure. III and VIII were sepd. from their mixt. by the MeOH-HCl method (Bredt, Ahrens and Menniken, *C. A.* **20**, 2157). III, acetobromoglucose and  $\text{Ag}_2\text{O}$  gave tetraacetyl- $\alpha$ -hydroxycamphor glucoside (X), m. 192-3°,  $[\alpha]_D^{25}$  -62.2° (oxime, m. 182-3°. Hydrolysis of X with Ba(OH)<sub>2</sub> gave the free glucoside (V), m. 82-3°,  $[\alpha]_D^{19}$  -6.1° (hydrated), m. 113-4° (anhyd. compd.). Tetraacetyl- $\beta$ -hydroxycamphor glucoside (XI), m. 152-3°,  $[\alpha]_D^{18.5}$  12.1°, was obtained in the same way with VIII as its aglycone. Semicarbazone, m. 116-7°. Sapon. of XI gave the free glucoside, m. 86-8° (decompn.),  $[\alpha]_D^{19}$  -13.7°. Due to negative reactions for the CO group in VIII and its alkyl ethers, Karrer (*C. A.* **19**, 2333) and Bredt (*C. A.* **20**, 2157) proposed a cycloacetal structure for them, but the ease of formation of the semicarbazone in XI shows that it has a free CO group and a cycloacetal structure is not necessary for XI or VIII.

NAO UYEH

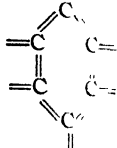

**Camphorone. I. Action of hydroxylamine.** G. SANNA. *Gazz. chim. ital.* **59**, 232 43(1929).—Though the action of  $\text{NH}_4\text{OH}$  (I) on camphorone (II) has been studied by several investigators, the results have been uncertain and the constitution of the compds. which were obtained have been in doubt (cf. Koenings and Eppens, *Ber.* **25**, 260(1892); **26**, 810(1893); Harries and Maftus, *Ber.* **32**, 1343(1899); Kerp and Muller, *Ann.* **290**, 143; Wallach, *Ann.* **331**, 318; Harries, *Gazz. chim. ital.* **39**, ii, 2(1909)). This induced S. to undertake a study of this reaction and allied reactions, the initial results of which are described in the present paper. New derivs. were prepd., the formation of which added a new exptl. confirmation of the theory of Harries (*Gazz. chim. ital.* **39**, ii, 2(1909)), and also gave an indirect proof of the constitution of II and its relation to pulegone. One of the new compds. represents the 1st example of a di-oxime among alicyclic ketones with a pentagonal nucleus. The I deriv. (III) of II described by Harries was prepd. according to his directions and was found to m.  $120^\circ$ . It reduces warm Fehling soln., gives a blue color with yellow  $\text{HgO}$  (characteristic of  $\text{NH}_4\text{OH}$  derivs. with the group on a tertiary C atom in  $\beta$ -position with respect to CO). (CO II), added to III (equimol. parts each in abs.  $\text{Et}_2\text{O}$ ) ppts. the oxalate of III, m.  $154^\circ$ . III in MeOH let stand several days with semicarbazide in dil. AcOH, filtered and the residue recrystd. from dil. MeOH, yields the semicarbazone of III,  $\text{C}_{16}\text{H}_{20}\text{O}_2\text{N}_4$ , decomp.  $190^\circ$ , reduces warm Fehling soln., gives a blue color with yellow  $\text{HgO}$ . Concd.  $\text{HNO}_3$  (d. 1.4) added dropwise to III (1 g.) in cold 26%  $\text{HNO}_3$  (5 cc. of d. 1.16) until  $\text{NO}_2$  vapors are no longer evolved, and until the mixt. no longer reduces Fehling soln., let stand several hrs., extd. with  $\text{C}_6\text{H}_6$ , and the ext. evapd., yields a nitro deriv., m.  $50^\circ$ . Concd. boiling aq.  $\text{HONH}_3\text{Cl}$  (5.6 g.) added to II (8 g.) in EtOH (40 cc.), concd.  $\text{Na}_2\text{CO}_3$  (calcd. quantity) then added, refluxed 2 hrs., filtered, the filtrate evapd. *in vacuo*, the residue let stand overnight until crystd. and then recrystd. from  $\text{Et}_2\text{O}$ , yields the oxime  $\text{C}_9\text{H}_{15}\text{ON}$  (IV), m.  $95^\circ$ , reduces hot Fehling soln., sol. in concd. alkalis and is repptd. only in part on diln. with water, decompd. by hot dil.  $\text{H}_2\text{SO}_4$  to an oil with the characteristics of II; treated in anhyd.  $\text{Et}_2\text{O}$  with  $\text{HCl}$  gas it turns brown and on evapn. *in vacuo* a brown oil is obtained which could not be solidified but which gave the reactions of oximes. I in MeOH (prepd. from 28 g. of  $\text{HONH}_3\text{Cl}$  and  $\text{NaOMe}$  (4 mols.)) added to II (15 g.), let stand 1 week, evapd. to a sirup on a water bath, dissolved in  $\text{Et}_2\text{O}$ , the soln. extd. repeatedly with small portions of 10% KOH (until the ext. satd. with  $\text{CO}_2$  gives no turbidity), the combined alk. exts. satd. with  $\text{CO}_2$ , let stand until the oil solidifies, the solid dissolved in boiling  $\text{Et}_2\text{O}$ , and recrystd. from  $\text{Et}_2\text{O}$ , yields camphoronehydroxylamine oxime,  $\text{C}_9\text{H}_{15}\text{O}_2\text{N}_2$  (V), m.  $160^\circ$ , sol. in acids and in alk. hydroxides, insol. in alk. carbonates, reduces cold Fehling soln., in org. solvents it is oxidized with air present, becoming an intense blue, oxidized still more rapidly by yellow  $\text{HgO}$ . If the oil formed by the action of  $\text{CO}_2$  in the prepn. of V is dried *in vacuo* over  $\text{H}_2\text{SO}_4$ , gas is evolved and a spongy mass remains. Let stand several days, then extd. with  $\text{Et}_2\text{O}$ , a cryst. residue is left, which, washed with  $\text{Et}_2\text{O}$  and recrystd. from  $\text{Et}_2\text{O}$ , yields camphorone oxime,  $\text{C}_9\text{H}_{15}\text{ON}$  (VI), m.  $115^\circ$  (decompn.), reduces hot Fehling soln., does not give a colored compd. with yellow  $\text{HgO}$ . It is an isomer of IV and of the oxime of Kerp and Müller (*Ann.* **290**, 143). The oil which remains after extn. with  $\text{Et}_2\text{O}$  does not crystallize even after a long time *in vacuo* or in the presence of water. It has the odor of mint and behaves like an oxime, though it is probably a mixt. To establish the constitution of V, it was treated with  $\text{BzH}$ , since it is known (cf. Bamberger and Rudolf, *C. A.* **1**, 2590) that  $\text{BzH}$  gives derivs. with the  $-\text{NCHPh.O}$  group.  $\text{BzH}$

(a little greater quantity than equimol.) refluxed with V in abs. MeOH for several hrs., cooled, concd. at a low temp. if not crystd., dild. with water, extd. with  $\text{Et}_2\text{O}$ , the ext. evapd., the residue dissolved in  $\text{Et}_2\text{O}$ -petroleum ether (equal parts), let stand several days, and the ppt. recrystd. from  $\text{Et}_2\text{O}$ -petroleum ether, yields benzalcamphoronehydroxylamine oxime,  $\text{C}_{16}\text{H}_{22}\text{O}_2\text{N}_2$  (VII), m.  $145^\circ$ . Hydroxylamines react with  $\text{BzCl}$ , but with V both the  $\text{NH}_2\text{OH}$  and the  $\text{NOH}$  groups react with formation of a di-Bz deriv. The reaction was carried out by the method of Schotten-Baumann, V being dissolved in  $\text{Na}_2\text{CO}_3$  with excess  $\text{BzCl}$ , cooled after the reaction is over, the ppt. freed of a small quantity of  $\text{BzOH}$  by  $\text{Na}_2\text{CO}_3$ , dissolved in  $\text{AcOEt}$ , and recrystd. from  $\text{AcOEt}$ , yields the di-Bz deriv.  $\text{C}_{23}\text{H}_{26}\text{O}_2\text{N}_2$  (VIII), turns brown  $160^\circ$ , m.  $168^\circ$  (decompn.). V, reduced with Na

(a little greater quantity than equimol.) the results indicate that the constitution of V is  $\text{HON} \cdot \text{C} \cdot \text{CHMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}(\text{NHOH})\text{Me}_2$ , of VI  $\text{HON} \cdot \text{C} \cdot \text{CHMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{C} \cdot \text{CMe}_2$ , of VII  $\text{HON} \cdot \text{C} \cdot \text{CHMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CHC}(\text{N.O. CHPh})\text{Me}_2$ , of VIII  $\text{Bz} \cdot$

ON: C. CHMe. CH<sub>2</sub>. CH<sub>2</sub>. CHC(NO<sub>2</sub>)Me<sub>2</sub> and of IX H<sub>2</sub>NCH. CHMe. CH<sub>2</sub>. CH<sub>2</sub>. CHC. (NH<sub>2</sub>)Me<sub>2</sub>.

Structural difference between synthetic and Japanese camphor. C. C. DAVIS. *Metallbörse* 18, 2414-6, 2528-9, 2640-1 (1928).—There is no proof of single and double bonds; the idea that double bonds are weaker than single bonds is untenable in a trustworthy structural formula for the terpenes. The energy of formation of liquid and gaseous benzene is different. In liquid benzene during evapn. there are set free unions which may recombine with one another to give the liquid, or with similar unions of other materials; i. e., besides the valence 4 given to the C atom, a further at. energy is possessed which is used in forming C<sub>2</sub>-mol. whether the C atoms are or are not combined with H. The simple mol. CH<sub>4</sub> does not exist, but the double, mol. H<sub>4</sub>C = CH<sub>4</sub>.

The binding power of C is represented by , and a ring of 6 C atoms thus, .

Different means of representing the structures of compds. according to this theory are given. In the chlorination of CH<sub>4</sub> the energy action of Cl on the double CH<sub>4</sub> mol results in the splitting out of 2H atoms from CH<sub>4</sub>, which combine with Cl<sub>2</sub>, and then 2HCl sep. by explosion. The CH<sub>2</sub> left from the CH<sub>4</sub> combines with HCl to give CH<sub>3</sub> - HCl, while the remainder of the HCl is liberated. The reaction is not one in which H is substituted by Cl, and the liberated H wanders to another Cl, but the H of CH<sub>4</sub> exists in 2 like pairs. On the basis of the foregoing theory formulas are derived for the xylenes, cymene, hexahydrocymene, pinene, camphene, isoborneol and synthetic and Japanese camphors. FREDERICK C. HAHN

Polyhydroxychalcones, -hydrochalcones and -flavanones. IV. Synthesis of 3',4'-dimethoxy-5,7-dihydroxyflavanone and the constitution of eriodictyol and homoeriodictyol. J. SHINODA AND S. SATO. *J. Pharm. Soc. Japan* 49, 64-70 (1929); cf. Tutin and Power, *Proc. Am. Pharm. Assoc.* 352, 52 (1906).—Employing the method of T. and P., S and S. have obtained eriodictyol (I) and homoeriodictyol (II) from *Eriodictyon californicum* 3,4-(MeO)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CH:CHCOCl (3.5 g.) and phloroglucinol (2 g.) in PhNO<sub>2</sub> (30 cc.) with AlCl<sub>3</sub> (5 g.) overnight gave a red-brown resin which, satd. in 10% KOH with CO<sub>2</sub>, gave 3',4'-dimethoxy-5,7-dihydroxyflavanone (III), m. 200° (oxime, m. 252°). Excess of CH<sub>2</sub>N<sub>2</sub> in Et<sub>2</sub>O with III gave 3',4',7-trimethoxy-5-hydroxyflavanone (IV). IV with Ac<sub>2</sub>O and a drop of concd. H<sub>2</sub>SO<sub>4</sub> gave the monoacetate, m. 155°. Acetylation of I and II as above gave acetyleriodictyol, m. 137°, and acetylhomoeriodictyol, m. 115-6°, resp. Oxime of II, m. 224°. I does not give an oxime. Methylation of I, II and hesperetin gave a product similar to IV, m. 136°. V. Synthesis of eriodictyol and homoeriodictyol. *Ibid* 71-8.—S. and S. have shown that the methylation product of eriodictyol (I), homoeriodictyol (II) and hesperetin are identical with 3',4',7-trimethoxy-5-hydroxyflavanone (*C. A.* 23, 836). They have now succeeded in synthesizing I and II. A mixture of carboxyferulyl chloride (4.2 g.) and phloroglucinol (2 g.) in PhNO<sub>2</sub> (30 cc.) with AlCl<sub>3</sub> (5 g.) was kept overnight and the excess of PhNO<sub>2</sub> was distd. off with steam. The residue satd. in 10% KOH with CO<sub>2</sub> gave a yellow ppt., m. 233°, which on recrystn. from AcOH gave colorless needles of II, m. 224-5°; oxime, m. 224°; Ac deriv., m. 163-4°; mono-Me deriv., m. 142-3°; di-Me deriv., m. 136°. The mixt. of dicarboxycaffeyl chloride (4.5 g.) and phloroglucinol (2 g.) in PhNO<sub>2</sub> (40 cc.) with AlCl<sub>3</sub> (7 g.) treated 1 hr. on the water bath and allowed to stand for 3-4 days gave a resinous substance. Reduction of this with Mg and HCl shows no flavanone reaction. It was heated in 5% KOH (200 cc.), in the presence of H, acidified with HCl, shaken with ether, treated with boiling water and filtered. The ppt. gave two constituents: alc.-insol. yellow crystals (III) and an alc.-sol. substance (IV). III, m. 267°, shows no flavanone reaction. IV gave colorless needles of I, m. 267°, which give the flavanone reaction with Mg and HCl, and contain 1 or 2.5 mol. of water of crystn. Tri-Me deriv., m. 136°; mono-Me deriv., m. 215°; Ac deriv., m. 137°. III is C<sub>24</sub>H<sub>18</sub>O<sub>8</sub>·2H<sub>2</sub>O and is identical with the product, m. 267-8°, obtained in the synthesis of naringenin (*C. A.* 23, 2956). F. I. NAKAMURA

Synthesis of substantive dyes derived from dicinnamoylmethane. W. LAMPE, Z. BUCZKOWSKA (Miss), J. FRENKL, E. GLIKSMAN-KORNGOLD, M. TOKARSKA-KOZLOWSKA (Miss), R. NELKEN AND C. SIERADZKA. *Roczniki Chem.* 9, 444-62 (463 German)

**Perylene and its derivatives. XXIII.** KONRAD FUNKE and HERBERT WOLF. *Monatsh.* 52, 1-6(1929); cf. *C. A.* 23, 3223.—3,9-Dichloro-4,10-dinitroperylene, reduced

with  $\text{PhNHNH}_2$  in  $\text{C}_6\text{H}_4\text{Me}_2$ , gives, after boiling 3.5 hr., the *4,10-diamino deriv.* (I), crystg. from 800 parts  $\text{C}_6\text{H}_4\text{Me}_2$  in orange-red needles;  $\text{PhNH}_2$  removes the halogen; cold concd.  $\text{H}_2\text{SO}_4$  gives a brown-red soln. with a strong sky-blue fluorescence, on warming it changes to a garnet-red with red fluorescence.  $\text{C}_6\text{H}_5\text{N}$  and  $\text{PhNO}_2$  give dark red solns. but I does not crystallize therefrom. *Di-Ac deriv.*, yellow-brown needles, sol. in concd.  $\text{H}_2\text{SO}_4$  with a green color and deep green fluorescence, changing on warming to garnet-red with red fluorescence. *Di-Bz deriv.*, yellow needles, sol. in concd.  $\text{H}_2\text{SO}_4$  with a sky-blue color, changing to green with a weak red fluorescence; warming gives a garnet-red color with a red fluorescence. 3,9-Dibromoperylene (5 g.) in 125 g.  $\text{AcOH}$ , 4 g.  $\text{KNO}_3$  in 10 cc.  $\text{H}_2\text{O}$  and 4.5 g. concd.  $\text{H}_2\text{SO}_4$  in 20 g.  $\text{AcOH}$  give 3 g. of the *1,10-dinitro deriv.*, light red needles from  $\text{PhNO}_2$  or  $\text{PhNH}_2$ ; the concd.  $\text{H}_2\text{SO}_4$  soln. is violet, changing to Bordeaux-red on warming. Reduction gives the *4,10-diamino deriv.* (II), crystd. from 1500 parts  $\text{C}_6\text{H}_4\text{Me}_2$ , during which some Br is lost. Heating either I or II with  $\text{PhNH}_2$  for 1 hr. gives *4,10-diaminoperylene*, deep steel-blue needles, sol. in  $\text{C}_6\text{H}_4\text{Me}_2$  with an olive-green color and pale green fluorescence and in  $\text{C}_6\text{H}_5\text{N}$  with a dirty brown color. The concd.  $\text{H}_2\text{SO}_4$  soln. is light violet and on warming shows a light brown fluorescence. *Di-Bz deriv.*, yellow needles, by heating II with  $\text{BzCl}$  in  $\text{C}_6\text{H}_4\text{Me}_2$  for 10 min. *Di-p-bromobenzoyl deriv.*, yellow needles. XXIV. ALFRED PONGRATZ. *Ibid* 7-12.—Perylene-3,9-dicarboxylic acid, obtained from the chloride or bromide through the cyanide, gives with  $\text{PCl}_5$  or  $\text{SOCl}_2$  an *acid chloride*, dark red needles, crystd. from 60 parts  $\text{PhNO}_2$ ; the  $\text{C}_6\text{H}_6$ ,  $\text{PhMe}$  and  $\text{C}_6\text{H}_4\text{Me}_2$  solns. are yellow and have a yellow-green fluorescence; the  $\text{PhNO}_2$  soln. is orange with an olive green fluorescence. With  $\text{C}_6\text{H}_6$  and  $\text{AlCl}_3$  at  $80^\circ$  for 3-4 min., there results 3,9 dibenzoyl perylene, m.  $291-2^\circ$ .  $\text{PhMe}$  gives a *di-m-* or *di-p-toluxyl perylene*, light yellow, m.  $309-10^\circ$ ; the concd.  $\text{H}_2\text{SO}_4$  soln. is blue; the  $\text{C}_6\text{H}_6$  or  $\text{C}_6\text{H}_4\text{Me}_2$  soln. is yellow with a green fluorescence. 3,9-Dinaphthoyl perylene, orange needles, m.  $321-2^\circ$ , sol. in concd.  $\text{H}_2\text{SO}_4$  with a blue color, in  $\text{C}_6\text{H}_6$  or  $\text{C}_6\text{H}_4\text{Me}_2$  with a yellow-brown color and green fluorescence. In  $\text{H}_2\text{SO}_4$ ,  $\text{MnO}_2$  gives a violet-blue compd., probably a dibenzisviolanthrone. XXV. ALOIS ZINKE AND WALTER HIRSCH. *Ibid* 13-22.—3,9,4,10-Tetrachloroperylene, warmed with 100 parts concd.  $\text{H}_2\text{SO}_4$  at  $140^\circ$  in an atm. of  $\text{CO}_2$  for 25 hrs., gives 3,4,9,10 perylene-diquinone, garnet-red needles; this has also been obtained from the 3,10-dinitro, the 3,4,9,10-tetranitro and the 3,9-dichloro-4,10-dinitro derivs. A cryst. product could not be obtained from hexachloroperylene, although it reacts with concd.  $\text{H}_2\text{SO}_4$  at  $140-50^\circ$ . 3,9-Dichloro-4,10-diacetyl perylene and concd.  $\text{H}_2\text{SO}_4$ , warmed 4 hrs. at  $120-5^\circ$ , give 3,9-perylenequinone, violet; the vat is red with an intense deep green fluorescence; with  $\text{BzCl}$  the vat gives the dibenzoate of 3,9-perylenehydroquinone, m.  $312-4^\circ$ ; similarly was prepd. the di-p-bromobenzoate, m.  $359-60^\circ$ . Oxidation with concd.  $\text{H}_2\text{SO}_4$  gives the above diquinone. The same quinone is obtained from 3,9-dichloro-4,10-dibenzoyl perylene and from 3,9-dichloroperylene. C. J. WEST

**The reduction of diphenylglycidic ester by means of sodium and absolute alcohol.** MME. PIERRE BILLON-BARDON. *Compt. rend.* 188, 1412-3 (1929); cf. C. A. 20, 3292. Like the  $\text{RMgX}$  compds. previously studied, Na and alc. react selectively on the ethylene oxide group of  $\text{Ph}_2\text{C}.\text{CH}(\text{CO}_2\text{Et}).\text{O}$  (I), rather than on the ester group. Thus I (1 mol)

with Na (18 atoms) yielded after acidification  $\text{Ph}_2\text{CHCH}(\text{OH})\text{CO}_2\text{H}$ , m.  $159^\circ$ , (about 60%),  $\text{CH}_2\text{Ph}_2$ , and a very small amt. of a product b<sub>16</sub>  $180-215^\circ$ . B. assumes that the first compd. formed is  $\text{Ph}_2\text{CHCH}(\text{ONa})\text{CO}_2\text{Et}$  (or in the previous cases  $\text{Ph}.\text{CRCH}(\text{OMgX})\text{CO}_2\text{Et}$ ) and that the group  $-\text{ONa}$  (or  $-\text{OMgX}$ ) in the  $\alpha$ -position to the  $-\text{CO}_2\text{Et}$  group renders the latter more inert or almost entirely inert toward the reagents used.

**2,3-Dinitro- and 1,4-dinitronaphthalene.** L. K. CHUDOŽILOV. *Collection Czechoslov. Chem. Comm.* 1, 302-5 (1929).—These compds. have been prepd. by the dehydrogenation of 6,7- and 5,8-dinitrotetralin (m.  $98-9^\circ$  and  $87-8^\circ$ , resp.) which were prepd. from the nitramines (see C. A. 17, 2111; 16, 1763). Attempts to prep. 2,7- $\text{C}_{10}\text{H}_6(\text{NO}_2)_2$  were unsuccessful. The 2,3-dinitronaphthalene was obtained in 10% yield as yellow crystals, m.  $170.5-1.0^\circ$ , sol. in alc. JANET D. SCOTT

**Derivatives of naphthalic acid.** KAROL DZIEWOŃSKI, OLGA GESCHWIND AND LUDWIK SCHIMMER. *Bull. intern. acad. polonaise* 1928A, 507-22 (In German).—Naphthalic anhydride when treated with fuming  $\text{H}_2\text{SO}_4$  at a low temp. yields 3 naphthal-sulfonic acid (naphthalene-1,8-dicarboxylic-3-sulfonic acid) (I). At higher temps. a disulfo deriv. (II) is obtained, which G. Bargellini (*Atti acad. Lincei* [5], 14, II, (688)) described as naphthal-3,6-disulfonic acid. The authors came to another conclusion. II may also be obtained by treating I with a new amt. of  $\text{H}_2\text{SO}_4$ ; thus position 3 of one sulfo group is confirmed. II fused with alkali gives dihydroxynaphthalic acid (III) (anhy-

dride, m. 330°; *di-Me ether*, m. 280°; *diacetate*, m. 260°; *benzoate*, m. 235–236°; *anilide*, m. 365°; *phenylhydrazone*, m. 252°), which can also be obtained by alkali fusion of 4-bromonaphthal-sulfonic acid (IV), a deriv. of 4,1,8- $C_{10}H_5Br(CO_2H)_2$  (V). Hence II can be only naphthal-3,5- or -3,4-disulfonic acid. Because copulation of III with diazo compds. gave no results, III is the 3,4-di-HO acid,  $C_{10}H_4(OH)_2(CO_2H)_2$ , and II the 3,4-di- $SO_3H$  acid,  $C_{10}H_4(SO_3H)_2(CO_2H)_2$ . IV is obtained by the action of fuming  $H_2SO_4$  on 4,1,8- $C_{10}H_5Br(CO_2O)$  and gives III when fused with alkali. The sulfo group is therefore in position 3 and IV is 4-bromonaphthal-3-sulfonic acid (Ba salt, needles; aniline salt, prisms, m. 270°; chloride, m. 183–184°; imido-amide, m. 338°). Similarly 4,1,8- $C_{10}H_5Cl(CO_2H)_2$  gave 4-chloronaphthal-3-sulfonic acid (aniline salt, m. 257°; chloride, m. 180–1°; imido-amide, m. 318°), which when fused with alkali again gave III. In connection with this work the little known  $\alpha$ -bromonaphthalic acid (V) was studied (Me ester, m. 102–3°; hydrazone, m. 217°; dinitro-4-bromonaphthalic anhydride, m. 234–5°). It gives by fusion with alkali 3,1,8- $C_{10}H_3(OH)(CO_2H)_2$ , changing position 4 into 3, as was already found with 4,1,8- $C_{10}H_5Cl(CO_2H)_2$  (cf. C. A. 21, 2682). Its anhydride m. 280°; 4-benzencazo-3-hydroxynaphthalic anhydride, m. 261°.

J. WIERTLAK

**Benzopolymethylene compounds. XVI. Heat rearrangement of  $\alpha$ -arylindenes into  $\beta$ -arylindenes.** JULIUS V. BRAUN AND GOTTFRIED MANZ. *Ber.* 62B, 1059–65 (1929), cf. C. A. 23, 2713.—Graebe in attempting to prep fluoranthene by heating 9-methylfluorene obtained a substance to all appearances identical with 9-methylphenanthrene just as he obtained phenanthrene itself from 9-methylfluorene. This rearrangement, involving, besides the elimination of H, the shifting of 1 of 2 aryl residues bound to the same C atom to an adjacent C atom, is apparently quite difficult in open chain compds.; no indications of it were observed with  $Ph_2CHMe$  or  $Ph_2C-CH_2$ .  $\alpha$ -Phenylindene (I) was accordingly chosen for study. Mayer, Sieglitz and Ludwig had already reported (C. A. 15, 3829) that I at red heat changes into an isomer which melts much higher, gives benzil-*o*-carboxylic acid on oxidation, adds neither Br nor  $H_2$ , is not formed from 2-phenylindanone (II) by reduction to the carbinol (III) and boiling with  $H_2SO_4$  and can therefore not be  $\beta$ -phenylindene (IV); they propose for it the structure V or VI. A repetition of their work has shown that all of it is not correct. The product adds catalytically activated H just as readily as indene, absorbs 2 atoms Br with the greatest ease and is nothing but IV as shown by its ready synthesis in 2 ways: from  $\beta$ -hydrindone with  $PhMgBr$  through the carbinol (VII) and from 2-phenylhydrindone through its oxime, the  $NH_2$  compd. (VIII) and the corresponding quaternary base (IX) which readily decomps into IV, for it is known that it is the H on the  $\beta$ -C atom to the N which is split off in the decompn. of quaternary  $NH_4$  bases. On the other hand, the work of Tiffeneau and his pupils on the so-called retropinacolin rearrangement has shown how greatly in a carbinol of type III splitting off of  $H_2O$  to form IX and then I is favored, and therefore the product obtained by M., S. and L. was probably nothing but I. The isomerization of I, in which short exposure to a high temp. produces a simple interchange in position between a H atom and a Ph group, is, as far as v. B. and M. are aware, without analogy. That no intermediate product such as VI is formed is indicated by the fact that  $\alpha$ -*p*-tolylindene (X) isomerizes to  $\beta$ -*p*-tolylindene (XI), which can also be obtained from  $\beta$ -hydrindone and *p*- $MeC_6H_4MgBr$ , whereas if an intermediate tetracyclic compd. (XII) were formed, the final product should be  $\beta$ -*m*-tolylindene (XIII) which was synthesized for comparison and found to be quite different from the rearrangement product of X. The yield of IV from I depends on the rapidity with which the I is distd. over the heated pumice, e. g., 33% when 10 g. I are distd. in 10 mm. As regards m. p., soly., compn. and mol. wt., the description of M., S. and L. was confirmed. With Pd-charcoal in MeOH it yields a *dihydro deriv.*,  $b_{10}$  162–3°,  $d_4^{20}$  1.0821,  $n_D^{20}$  1.5955. Dibromide, prepd. in  $CS_2$ , m. 130–1°. VII, faintly yellow, very thick oil,  $b_{0.5}$  160–5°. VIII (50% from the indanone oxime in MeOH-AcOH with Na-Hg),  $b_{10}$  180–4°; *picrate*, yellow, decomp. 121–3°, gives with aq.  $Me_2SO_4$  and then with KI-NaOH 70% of the hygroscopic quaternary methiodide (IX). X, from  $\alpha$ -hydrindone and *p*- $MeC_6H_4MgBr$ , thick yellowish oil,  $b_{11}$  184–8°. XI, leaflets with faint bluish fluorescence, m. 183–4°; the intermediate carbinol in its synthesis from  $\beta$ -hydrindone  $b_{0.2}$  155–6°. XIII, m. 99–100°; the intermediate carbinol  $b_{0.5}$  165–70°.

The absorption spectra of *N*-aminonaphthalimide and some of its mono- and disubstituted *N*-derivatives. A. OSTROGOVICH AND ELENA TÂNĂȘESCU. *Bull. soc. stiinte Cluj* 4, 368-98(1929).—*N*-Phenylaminonaphthalimide, and the following di-*N*-derivs. of 1,8- $C_{10}H_6(CO)_2NNH_2$  were prepd. and their absorption spectra studied in the visual portion of the spectra. Methylphenyl, m. 214-15°; ethylphenyl, m. 151-2°; propylphenyl, m. 154-5°; Ph, m. 108-9°; cetylphenyl, m. 97-9°; *o*-tolyl, m. 248-9°; *m*-tolyl, m. 209-10°; *p*-tolyl, m. 207-8°;  $\alpha$ -naphthyl, 277-8° (decompn.);  $\beta$ -naphthyl, m. 268°; *o*-nitrophenyl, m. 281-2°; *p*-nitrophenyl, m. above 300°. The following  $\alpha$ -alkyl- $\alpha$ -phenylhydrazine-HCl salts were also prepd.: Pr, m. 130-1°; hexyl, m. 77-8°; cetyl, m. 62°. WALLACE R. BRODE

The oxidation of anthracene with nitric oxide. M. IL'INSKII AND B. MAKOROV. *Z. Farbenind.* 20, 210-2(1929); cf. *C. A.* 22, 3888.—Pure anthracene and NO in  $PhNO_2$  give anthraquinone.  $PhNO_2$  is not affected by the NO. By means of this process crude anthracene may be converted to anthraquinone which may be sep'd. from the by-products which accompany crude anthracene. FREDERICK C. HAHN

Synthesis of trihydroxymethylanthraquinone derivatives. II. Constitution of chrysarone. S. KEIMATSU, I. HIRANO AND T. TANABE. *J. Pharm. Soc. Japan* 49, 419-25(1929).—In a previous publication (*C. A.* 23, 3464) the authors have reported the synthesis of a trihydroxymethylanthraquinone and shown that it was identical with the chrysarone of Hesse, but its structure was not studied. *Trichloromethylanthraquinone* (I) (3 g.) and Br (9 g.) at 160-70° gave 2-*o*-dibromomethyl-3,5,6-trichloroanthraquinone (II) m. 245-6°. II (9.6 g.), concd.  $H_2SO_4$  (65 cc.) and 25% fuming  $HNO_3$  (12 cc.) at 110-30° gave 3,5,6-trichloroanthraquinone-2-aldehyde (III), m. 235-6°. Oxidation of III (3.5 g.) with  $K_2Cr_2O_7$  (3 g.) in  $AcOH$  (20 cc.) gave 3,5,6-trichloroanthraquinone-2-carboxylic acid (IV), m. 305-6°. IV heated at 305-10° gave 3,5,6-trichloroanthraquinone (V), m. 259-60°. IV (1.2 g.) and  $MeONa$  treated at 150-70° for 7 hrs. gave 3,5,6-trimethoxyanthraquinone-2-carboxylic acid (VI), m. 254-5°. VI (0.7 g.) heated at 254-5° for 1 hr. gave 3,5,6-trimethoxyanthraquinone (VII), m. 200-1°. VII is identical with anthrapurpurin tri-Me ether (cf. Graebe and Bernhard, *Ann.* 349, 226). VII (0.6 g.) and 60°  $B_6$   $H_2SO_4$  (20 cc.) heated for 3 hrs. gave 3,6-dimethoxy-5-hydroxyanthraquinone (VIII), m. 240-1°. VIII is identical with the anthrapurpurin 2,7-di-Me ether of Graebe. VII (0.3 g.) with Br and  $AcOH$  (30 cc.) heated for 6 hrs. gave 3,5,6-trihydroxyanthraquinone (IX), m. 372-4°. IX decomp. at its m p and the product is identical with anthrapurpurin, m. 369° (cf. Romer and Schunk, *Ber* 11, 972). It is certain that I and chrysarone are 3,5,6-trichloro- and 3,5,6-trihydroxy-2-methylanthraquinone, resp. F. I. NAKAMURA

Hydrogenation of anthroic acid and the question of the existence of two isomeric 9,10-dihydroanthracene-9-carboxylic acids. HANS MEERWEIN AND ARMIN MIOGE. *Ber.* 62B, 1046-50(1929).—Among the isomers observed by Schlenk and Bergmann which cannot be explained by present conceptions on stereochemistry and which led them to suggest that the planes of the rings in condensed cyclic systems are inclined to each other (*C. A.* 22, 4495) are two 9,10-dihydroanthracene-9-carboxylic acids (I and II). They obtained I by the action of  $CO_2$  on the mono-Na addn product of anthracene and II by the hydrogenation of anthracene-9-carboxylic acid (III) in boiling  $PrOH$  with  $H_2$  and  $Pd-BaSO_4$ . Strangely enough, however, both yield the same Me ester with  $CH_3N_3$  and this led M. and M. to repeat their work. As regards I, they fully confirmed the results of S. and B.; the product obtained m. 204-5°. Its Me ester m. 97-8°. The reduction of III, however, gave them results different from those of S. and B. During the hydrogenation  $CO_2$  was split off and from the  $Na_2CO_3$ -sol part (about 20-30%) of the product they isolated 1,2,3,4-tetrahydroanthracene, m. 104-5°, and smaller amts. of the 1,2,3,4,5,6,7,8-octahydro deriv., m. 72-4°. The  $Na_2CO_3$ -sol. part of the product was also a mixt. of I and, chiefly, tetrachloro-9-carboxylic acid (1,2,3,4-tetrahydroanthracene-9-carboxylic acid) (IV). None of S. and B.'s II was obtained, and it is probable that their product was a mixt. IV, m. 204.5-5.5°, Me ester, m. 67-8°.  $CrO_3$  oxidizes IV to tetracenequinone, m. 157-8°. Under cathode rays III shows intense yellow-green fluorescence, I a greenish yellow glow and bluish afterglow, IV an intense light blue glow and tetracene a violet glow. C. A. R.

The tautomerism of  $\alpha$ -diketones. The states of equilibrium. HENRI MOUREU. *Compt. rend.* 188, 1413-6(1929); cf. *C. A.* 22, 1341, 3155; 23, 2705.—The same state of equil. is reached by starting from either 1 of 2 tautomers, as shown, e. g., by a detn. of  $n$ . For  $PhCH_2COCOMe$ ,  $n_D^{20}$  of the equil. mixt. at 80° (the point of the greatest deviation between the 2 series of measurements) = 1.592 starting from tautomer A (heating it), or 1.595 from B, when the  $n$ 's for pure A and B are resp. 1.627 (calcd.) and 1.519 (detd.). From  $n$  the compn. at equil. can be detd. A curve is given showing

the % of A (always more than 50) at different equil. temps. obtained by starting from each isomer. The alkyl. of the glass walls or a very small amt. of  $C_6H_{11}N$  with a trace of  $H_2C_2O_4$  serves as catalyst. With  $PhCH_2COCOPh$  the equil. is strongly in favor of B. The agreement at equil. of the transformations in opposite directions is surprisingly good. **Heat of transformation of tautomers.** *Ibid* 1557-8.—The heat of transformation ( $Q$ ) calcd. from the integrated form of van't Hoff's equation,  $Q = \log (K_2/K_1) \times 1985 T_1T_2/(T_1 - T_2)$ , was 2.6 large cal. per mol. (mean of 4 values) for  $PhCH_2CO-COMe$  (I) and 2.7 for  $PhCH_2COCOPh$ . Calcd. from the heats of combustion the values for the same compds. were resp. 2.1 and 2.3 (in the case of I, since isomer A is solid and B liquid, the heat of fusion,  $L$ , of A enters into the calcn. of  $Q$  and is calcd. from  $L = 0.01985 T^2/k$ ,  $T$  being the abs. temp. of the m. p. of A, and  $k$  the f. p. const. of A, detd. by measuring the lowerings of the m. p. of A in mixts. of A and B. The values for  $Q$  are close, considering how different are the 2 methods used.  $Q$  for  $\alpha$ -diketones is hence of the order of 2.5 large cal. per/mol. JANET D. SCOTT

**Indoline and  $\alpha$ -methyl- $\beta$ -tetrahydroindole.** G. PLANCHER. *Ber.* 62B, 1088-9 (1929).—In connection with Ferber's report (*C. A.* 23, 2714) on a new synthesis of  $\alpha$ -dihydroindole (indoline) and the comparison of his product with that of v. Braun, P. points out that he and Ravenna had prepd. the compd. 7 yrs. before v. B. (*Atti accad. Lincei* [5], 14, I, 632(1905)). P. also calls attention to his prepn. with Zambonini of  $\alpha$ -methyl- $\beta$ -tetrahydroindole from  $AcCH_2CO_2Et$  and  $\alpha$ -chlorocyclohexanone, followed by sapon. of the resulting carbethoxy deriv. and distn. over lime (*Atti soc. progresso science Roma*, 1911, 828). C. A. R.

**Halogenated ketones of indole.** I. G. SANNA. *Gazz. chim. ital.* 59, 169-81 (1929).—Expts. on the prepn. of diketones of indole and methylindole (cf. *C. A.* 11, 1639, 2883) were continued by the prepn. of halogenated derivs. These derivs. should be of importance because from them it should be possible to synthesize other compds. which are similar to decompn. products of albuminoids and which are constituent parts of certain alkaloids. To avoid the ambiguity of some authors in designating widely differing groups by the term indoyl and to simplify the nomenclature, the radicals  $C_8H_7NH$ ,  $CH$ ,  $CCOCH_2$ ,  $C_6H_4$ ,  $NH$ ,  $CMe$ ,  $CCOCH_2$ —and  $C_6H_4$ ,  $NH$ ,  $C(COCH_2)$ —C—

Me, are termed *indacyl*,  $\alpha$ -methylindacyl and  $\beta$ -methylindacyl, resp. This agrees with the current usage for the corresponding aromatic radicals.  $ClCH_2COCl$  (10 g.) in anhyd  $Et_2O$  (3 vols.) added drop by drop to ice-cold magnesiummethylindole (I) (from 2.1 g. Mg, 10 g.  $EtBr$  and 11.5 g. methylketole), let stand cold for 12 hr., ice added and agitated vigorously, the  $Et_2O$  layer decanted, the aq. layer filtered, the residue washed with  $Et_2O$ , and recrystd. repeatedly from boiling  $C_6H_6$ , yields 60% of  $\alpha$ -methylindacyl chloride ( $\beta$ -chloroacetyl- $\alpha$ -methylindole),  $C_6H_4$ ,  $NH$ ,  $CMe$ :  $CCOCH_2Cl$  (II), m.

220°, burns the skin and mucous membranes, sol. in aq. alkalis and in concd.  $H_2SO_4$ ; its soln. in  $HNO_3$  is yellow and in  $HCl$  pale rose; it is repdtd. from its acid soln. by great diln.; it reduces hot Fehling soln. and  $NH_3$ - $AgNO_3$ ; with  $HgCl_2$ ,  $HgNO_3$ ,  $AuCl_3$ , and  $PtCl_4$ , it gives white ppts.; with alkaloid reagents it gives variously colored ppts. Dil  $NH_3$ - $AgNO_3$  added to hot very dil. aq. II in darkness, filtered and the ppt. washed with water,  $EtOH$  and  $Et_2O$ , yields the *Ag deriv.*,  $C_6H_4$ ,  $NAg$ :  $CMe$ :  $CCOCH_2Cl$ . With-

out  $NH_3$  there is no ppt. Dil.  $Na_2CO_3$  added drop by drop to II (0.50 g.) suspended in hot water until soln. is completed,  $KMnO_4$  (0.73 g. in 40 cc. water) added drop by drop, heated until colorless, cooled, filtered, acidified with dil.  $H_2SO_4$ , extd. repeatedly with  $Et_2O$ , the ext. agitated with concd. aq.  $Na_2CO_3$ , the 2 layers sepd., the aq. layer acidified with dil.  $H_2SO_4$ , again extd. with  $Et_2O$ , the ext. concd., and the ppt. recrystd. from dil.  $AcOH$ , yields  $\alpha$ - $C_6H_4(CO_2H)NHAc$  (III). II in dil.  $AcOH$  heated gently for 0.5 hr. with aq.  $PhNHNH_2OAc$  (1 mol.), let stand several days, dild. with water until turbid, heated gently a few min., let stand, and the ppt. recrystd. from  $C_6H_6$  or  $Et_2O$ , yields a *phenylhydrazone*,  $C_6H_4$ ,  $NH$ :  $CMe$ :  $CC(NNHPh)CH_2Cl$ , m. 134° (decompn.).

II (0.50 g.) heated a short time in pure  $C_6H_5N$  (10 cc.) below its b. p., cooled, the excess  $C_6H_5N$  decanted, the residual oil dissolved in  $EtOH$ , and purified from this solvent, with recrystn. from  $Et_2O$ , yields  $\alpha$ -methylindacylpyridonium chloride,  $C_6H_4N(Cl)CH_2CO$ :  $CMe$ :  $NH$ :  $C_6H_4$  (IV), m. 332°; its aq. soln. is alk. and gives the reactions of the  $Cl$

ion (giving ppts. with metallic chlorides). With 50%  $KOH$ , concd. aq. IV ppts. a yellow compd. (V) which was not analyzed because of its small quantity but which was probably  $C_6H_5N(OH)CH_2CO$ :  $CMe$ :  $NH$ :  $C_6H_4$ . Treating I with  $BrCH_2COCl$  under

the same conditions used in the prepn. of **II**, yields 70% of  $\alpha$ -methylindacyl bromide,  $C_6H_4.NH.CMe:CCOCH_2Br$  (**VI**), m.  $204^\circ$ , attacks the skin and mucous membranes,

has the same general properties as **II**. *Ag salt*. Oxidation with  $KMnO_4$  forms **III**. With  $C_6H_5N$ , and quinoline, it forms *addn. compds.* and also with  $PhNH_2$ , coumarone, oxazole, thiazole, thiazoline, quinoxaline, pyrazine, etc., which will be studied further. Fused with  $KOH$  it forms  $C_6H_4.NH.CMe:CCO_2H$ . **VI** also reacts with  $NH_3$  and with

$K$  phthalimide. In general its  $Br$  atom is more labile than the  $Cl$  atom in **II**. **II** and **VI** react extremely slowly with  $NH_2OH$ , perhaps because they exist in either one of 2 tautomeric forms:  $C_6H_4.NH.CMe:CC(OH):CHCl$  or  $C_6H_4.NH.CMe:CCH.CHCl$ , O,

which may exist in equil. with the normal form.  $\alpha$ -Methylindacyl iodide,  $C_6H_4.NH.CMe:CCOCH_2I$ , was prepd in a similar way to **II** and **VI**, and also by the

action of  $KI$  on **VI**. It will be described fully in a forthcoming paper. C. C. D.

**Imidazole derivatives. IV.** The breakdown of histidine to  $\gamma$ -hydroxyornithine, WOLFGANG LANGENBECK and RUDOLF HUTSCHENREUTER. *Z. physiol. Chem.* 182, 305-10(1929); cf. *C. A.* 22, 2356.—The unsatd. tribenzoyltri amino acid ester,  $Bz.NHCH:C(NHBz)CH_2CH(NHBz)CO_2Me$ , obtained by treatment of *L*-histidine  $Me$  ester with  $BzCl$  in  $Na_2CO_3$  soln., is structurally related to ornithine, and should be capable of yielding ornithine derivs. It was converted to the keto ester,  $BzNHCH.COCH_2CH(NHBz)CO_2Me$ , by treatment with  $MeOH-HCl$  according to Windaus, Dörries and Jensen (*C. A.* 16, 1427). Simple hydrogenation of this keto ester was then expected to yield ornithine. However, catalytic hydrogenation reduced the  $CO$  only as far as  $CHOH$ , and the secondary alc. grouping then condensed with the  $CO_2Me$  to form the lactone of  $\alpha,\delta$ -di[hexahydrobenzoylamino]- $\gamma$ -hydroxyvaleric acid, m.  $222^\circ$ . The mother liquor yielded a small amt. of an isomer, m.  $248^\circ$ . The lactone dissolves slowly in dil. alkali and from this soln. the free acid, m.  $236-40^\circ$ , may be obtained by careful addn. of  $AcOH$ . Even at  $0^\circ$  the  $Na$  salt becomes partially racemized and addn. of acid then yields some of the higher-melting lactone. Sapon of the lactone by  $HCl$  gave hexahydrobenzoic acid which was extd by  $H_2O$ , but no hydroxyornithine could be isolated from the aq. soln. Either the hydroxyornithine is destroyed in the sapon, or its phosphotungstate is sol. Perhaps for that reason it has not yet been found among the hexone bases. A. W. DOW.

**2-N-Nitrophenyl-1,2-naphtho-1,2,3-triazolequinones.** M. GALLOTTI (WITH ALBERTO ERCOLI). *Gazz. chim. ital.* 59, 207-11(1929).—By the action of  $HNO_3$  on 2-N-phenyl-1,2-naphtho-1,2,3-triazolequinone, Charrier and Manfredi obtained a dinitro deriv. to which they assigned a structural formula (cf. *C. A.* 20, 2859), which they believed was well proved. Nevertheless it was considered by G. that further expts should be carried out to establish the constitution of this dinitro deriv. and of similar derivs. The present paper, which is a preliminary one, deals with the prepn. of  $NO$  derivs. of 2-N-phenyl-1,2-naphtho-1,2,3-triazole (**I**), from which it was likely that by oxidation the corresponding nitrophenylnaphthotriazolequinones would be obtained.  $CrO_3$  (27 g. in a min. of water) added during 3 hr. to 2-N-o-nitrophenylnaphthotriazole (**II**) (cf. *J. Chem. Soc.* 59, 373(1891)) (15 g.) in a mixt. of glacial  $AcOH$  (800 g.) and  $Ac_2O$  (250 g.) at  $110^\circ$ , cooled, and the ppt. recrystd. from glacial  $AcOH$  and  $PhMe$ , yields 13 g. of 2-N-o-nitrophenyl-1,2-naphtho-1,2,3-triazolequinone (**III**), orange-yellow, m.  $267^\circ$ . o- $C_6H_4(NH_2)_2$  and **III** in boiling  $AcOH$  ppt. the phenazine (**IV**) of **III**, light

yellow, m.  $277-8^\circ$  (after recrystn. from xylene). **III** and  $PhHNNH_2Cl$  in boiling  $AcOH$  ppt. the hydroxyazo deriv. (**V**) of **III**, lustrous red, m.  $229^\circ$  (after recrystn. from boiling xylene). Oxidation of **III** with alk.  $KMnO_4$ , or oxidation of **II** or of o-nitrophenylazo- $\beta$ -naphthylamine with  $CrO_3$  in glacial  $AcOH$  and  $Ac_2O$ , and the product purified by

repeated salification with NaOH and reprecipitation with HCl, yields 2-*N*-*o*-nitrophenyl-1,2-naphtho-1,2,3-triazole (VI), m. 260°. Similarly to the preparation of III, 2-*N*-*m*-nitrophenyl-1,2-naphtho-1,2,3-triazole, m. 226.5° (cf. 223–4° of Meldola and Hughes, *J. Chem. Soc.* **59**, 379 (1891)), forms 2-*N*-*m*-nitrophenyl-1,2-naphtho-1,2,3-triazolequinone (VII), light yellow, m. 237–8°. Similarly to the corresponding derivs. of II were prepared the following 3 derivs. of VII: phenazine, yellowish, m. 328°; hydroxyazo deriv., orange-red, m. 255°; 2-*N*-*m*-nitrophenyltriazole-phenyl-*o*,*o'*-dicarboxylic acid, m. 274°. Similarly were prepared 2-*N*-*p*-nitrophenyl-1,2-naphtho-1,2,3-triazolequinone, lemon-yellow, m. 207°, and the following 3 derivs.: phenazine, m. 312°; hydroxyazo deriv., red, m. 240°; 2-*N*-*p*-nitrophenyltriazole-phenyl-*o*,*o'*-dicarboxylic acid, m. 267°. C. C. DAVIS

**Chloropyridino derivatives of rhodium. Tripyridinorhodium trichloride.** Dipyrindinorhodium tetrachloride. MARCEL DELÉPINE. *Bull. soc. chim.* **45**, 235–49 (1929).—A close parallelism is found with trivalent iridium pyridino compds., extending to solubilities and color of the two series: *cis*, orange; *trans*, red. 3 g.  $\text{RhCl}_6\text{Na}_3 \cdot 12\text{H}_2\text{O}$  and 2.4 g.  $\text{C}_5\text{H}_5\text{N}$  dissolve in 12 g.  $\text{H}_2\text{O}$ . Heating yields a yellow cryst. mixture. Boiling the  $\text{CHCl}_3$ -alc. mixt. leaves the insol.  $\text{RhPy}_2\text{Cl}_3 \cdot 2\text{CHCl}_3$ , orange-red, octahedral, losing 2  $\text{CHCl}_3$  on exposure to the air. Boiling alc. abs. extracts the yellowish orange *cis* form, which crystallizes without alc.  $\text{NH}_3$  at waterbath temp. changes it to  $[\text{RhCl}(\text{NH}_3)_2\text{Cl}_2]$ , pyridine to  $[\text{RhCl}_2\text{Py}_2\text{Cl}]$ . Heating the tripyridino trichloride with aq. pyridine in sealed tubes, at 130° yields  $[\text{RhCl}_2\text{Py}_4]\text{Cl} \cdot 6\text{H}_2\text{O}$ , bright yellow leaflets. Agitating  $\text{RhCl}_3\text{Na}_3$  with pyridine (6 mols.) and its HCl salt (4 mols.) in the cold yields *cis*- and *trans*- $[\text{RhPy}_2\text{Cl}_4] \cdot \text{C}_5\text{H}_5\text{N}$ . Extn. with hot water leaves the more difficultly sol. red (*trans*) crystals. The yellow (*cis*) form easily hydrolyzes to the hydrate salt  $[\text{Rh}(\text{H}_2\text{O})\text{Py}_2\text{Cl}_3]$ . KOH in dil. soln. displaces the basic pyridine, forming the dipyrindino (*cis*) compd.:  $[\text{RhPy}_2\text{Cl}_4] \cdot \text{K} \cdot 11\text{H}_2\text{O}$ , orange needles, of the same habit as the corresponding Ir salt. It loses 1  $\text{H}_2\text{O}$  at 100°. Adding  $\text{CaH}_2\text{NCl}$  to a soln. of the latter changes it to  $[\text{RhPy}_2\text{Cl}_4] \cdot \text{C}_5\text{H}_5\text{N}$ ,  $\text{NH}_4\text{Cl}$  and  $\text{AgNO}_3$ , similarly, produce  $[\text{RhPy}_2\text{Cl}_4] \cdot \text{NH}_4$ ,  $1\text{H}_2\text{O}$  and  $[\text{RhPy}_2\text{Cl}_4] \cdot \text{Ag}$ . The hydrate salt  $[\text{Rh}(\text{H}_2\text{O})\text{Py}_2\text{Cl}_3] \cdot 11\text{H}_2\text{O}$  did not yield  $[\text{RhPy}_2(\text{OH})\text{Cl}_3] \cdot \text{Ag}$ , as expected, but added  $\text{AgNO}_3$  completely:  $[\text{RhPy}_2(\text{H}_2\text{NO})\text{Cl}_3] \cdot \text{Ag} \cdot 2\text{H}_2\text{O}$ , long yellow needles. Corresponding red (*trans*) salts were prepared.  $[\text{Rh}(\text{H}_2\text{O})\text{Py}_2\text{Cl}_3] \cdot 1\text{H}_2\text{O}$ , (*trans*), loses 1  $\text{H}_2\text{O}$  at 110°, but 1.5  $\text{H}_2\text{O}$  at 130°, undergoing a constitutional change, since it is no longer sol. in alkali:  $\text{Rh}_2(\text{HO})\text{Py}_4\text{Cl}_6$ , fine, red needles.  $\text{RhCl}_6\text{Na}_3 \cdot 12\text{H}_2\text{O}$ , mixed with  $\text{C}_5\text{H}_5\text{N}$  only yields an additional product, insol. in  $\text{NH}_3$ , the analysis indicating a complex substance:  $[\text{RhPy}_2\text{Cl}_4] \cdot [\text{RhPy}_3(\text{H}_2\text{O})\text{Cl}_2]$ . The orange (*cis*) dipyrindino salt, on heating with pyridine, goes directly to the tetrapyrindino compd.; the corresponding red (*trans*) salt yields an insol., salmon-colored intermediate  $[\text{RhPy}_2\text{Cl}_4] \cdot [\text{RhPy}_3(\text{H}_2\text{O})\text{Cl}_2]$ . Attempts to prepare dipyrindino compds. of quadrivalent Rh were unsuccessful, which is surprising in view of the ease with which a corresponding Ir compd. may be prepared. K. H. ENGEL

**The picolide of M. Scholtz and the acetyl derivatives of indolizine and 2-methylindolizine.** A. I. CHICHIBABIN AND P. N. STEPANOV. *Ber.* **62B**, 1068–75 (1929).—By heating picoline with  $\text{Ac}_2\text{O}$  at 200–20° Scholtz obtained a compd.  $\text{C}_{12}\text{H}_{11}\text{O}_2\text{N}$  (I), designated by him as picolide, which with boiling concd. HCl gave II, first known as pyrrocoline but which may now more appropriately be named indolizine or pyrrodine. Since only one Ac group can be detected in I with the usual ketone reagents, S. assigned to it the structure III. With  $(\text{EtCO})_2\text{O}$   $\alpha$ -picoline does not give a product analogous to I but a compd.  $\text{C}_{12}\text{H}_{13}\text{ON}$  (IV) which S. and Fraude represented by the formula V. It seemed to C. and S. much more probable, however, that I and IV both contain the II nucleus, I being the 1,3-di-Ac and IV the 1-methyl-3-propionyl deriv. The formation of I could then be explained as follows: the  $\alpha$ -picoline first forms the  $\omega$ -di-Ac deriv.,  $\alpha\text{-C}_5\text{H}_7\text{NCH}(\text{OAc})_2$ , which, in its tautomeric form VI changes through the compd. VII into the 3-Ac deriv. of II and this is converted by a 2nd mol. of  $\text{Ac}_2\text{O}$  into I. With  $(\text{EtCO})_2\text{O}$  the reaction stops at the 3-acyl deriv. (IV) because there is a Me group on the 1-C atom. The only fact which is in a way not in harmony with this view is that no ketone reactions could be detected for the second Ac group in I. But there are many indications in the literature that the ease with which ketone reactions take place is diminished in *N*-methylpyrrole derivs. with acyl groups in the  $\alpha$ -positions, and accordingly C. and S. made a thorough study of the Ac derivs. of II and its readily available 2-Me homolog (VIII). With boiling  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  VIII gave a cryst. mono-Ac deriv. (IX), which is beyond doubt the 1-Ac deriv.; it gives the usual ketone reactions only with great difficulty, does not react with  $\text{NH}_2\text{OH}$  or  $\text{PhNHNH}_2$  under the usual conditions, reacts only difficultly with organo-Mg compds. and apparently does not give the normal products. With  $\text{Ac}_2\text{O}$  at 220° it forms a di-Ac deriv. (X), believed to be the 1,3-compd., in which, as in I, only one Ac group readily gives the

usual ketone reactions; *e. g.*, with  $\text{PhNHNH}_2$ , it forms a monophenylhydrazone. When **X** is heated under the conditions used by Scholtz to obtain **II** from **I**, it regenerates **VIII**. His mono-Ac deriv. (**XI**) of **II** with  $\text{Ac}_2\text{O}$  at  $220^\circ$  gives **I**. These results prove beyond doubt that **I** is the 1,3-di-Ac deriv. of **II**. **IX**, yellowish,  $b_p$   $159-60^\circ$ ,  $b_d$   $174-5^\circ$ ,  $m$ .  $83^\circ$ , does not change in the air when perfectly pure, is slowly volatile with steam; alc. solns. give a cherry-red pine splinter reaction. **X** (3.75 g. from 10 g. **IX**), yellowish,  $m$ .  $123^\circ$ ; alc. solns. give no pine splinter reaction even after several hrs. although on very long standing there gradually appears a red color; phenylhydrazone, yellow,  $m$ .  $210^\circ$  (decompn.). **XI**,  $b_p$   $148-9^\circ$ , gives a bright cherry-red pine splinter reaction.

**Condensation of quinaldine with chloro aldehydes.** H. KONDO AND T. MATSUNO. *J. Pharm. Soc. Japan* 49, 445-57 (1929).—Condensation of quinaldine with  $\text{CCl}_3\text{CHO}$  was previously reported by Einhorn (*cf. Ber.* 18, 3465). Employing the same method, condensation of quinaldine with mono- and dichloroacetaldehyde was studied. Condensation of  $\text{C}_{10}\text{H}_7\text{N}$  (10 g.) with  $\text{Cl}_2\text{CHCHO}$  (15 g.), using  $\text{ZnCl}_2$  (0.5 g.), gave 2-[ $\gamma$ -dichloro- $\beta$ -hydroxypropyl]quinaldine (**I**),  $\text{C}_{12}\text{H}_{11}\text{NOCl}_2$ ,  $m$ .  $143^\circ$  (yield 5% of theory). Condensation of quinaldine with  $\text{CH}_2\text{ClCHO}$  under different conditions (control of the reaction temp., time and condensing agent) failed to produce any product. Dehydration of **I** (2 g.) in  $\text{CHCl}_3$  with  $\text{PCl}_5$  (3 g.) or **I** (2.5 g.) in  $\text{Et}_2\text{O}$  with  $\text{SOCl}_2$  (2 g.) gave  $\gamma$ -dichloro- $\alpha$ -[2-quinolyl]propene (**II**),  $m$ .  $131^\circ$  (yield 1-2 g.). Reduction of **II** (1.5 g.) in  $\text{AcOH}$  with  $\text{Pd}$  and **C** gave  $\gamma$ -dichloro- $\alpha$ -[2-quinolyl]propane (**III**).  $\text{Pt}$  salt of **III**, decompn.  $192-4^\circ$ . Further reduction of **III** (1.2 g.) with 38%  $\text{HCl}$  (10 g.) and  $\text{Zn}$  (5.5 g.) gave 2-[ $\gamma$ -dichloropropyl]-1,2,3,4-tetrahydroquinoline (yield very small). Reduction of **II** (2 g.) with 38%  $\text{HCl}$  (20 g.) as above gave 2-[ $\gamma$ -dichloropropenyl]-1,2,3,4-tetrahydroquinoline (**IV**). Reduction of **IV** (0.2 g.) with  $\text{Pd}$  and **C** gave **V**,  $m$ .  $235-48^\circ$ . Picrate of **V**  $m$ .  $160^\circ$ ; a mixed  $m$ . p. with picrate of **IV** ( $m$ .  $158^\circ$ ) gives  $159^\circ$ , hence **V** is identical with **IV**. The properties of the tri-Cl deriv. (condensation product of  $\text{CCl}_3\text{CHO}$  and quinaldine) were also studied. F. I. NAKAMURA

**Condensation of o-aminobenzaldehyde with esters of ketodicarboxylic and diketocarboxylic acids.** GEORG KOLLER, HILDEGARDE RUPPERSBERG AND ELSE STRANG. *Monatsh.* 52, 59-67 (1929); *cf. Koller and Strang, C. A.* 22, 3663.—Condensation of 3.55 g.  $\text{CO}(\text{CH}_2\text{CO}_2\text{Et})_2$  and 2.13 g.  $o\text{-H}_2\text{NC}_6\text{H}_4\text{CHO}$  (**I**) in 25 cc.  $\text{EtOH}$  with 0.02 g.  $\text{NaOH}$  gives 3.9 g. of the compd.  $\text{C}_{18}\text{H}_{17}\text{O}_4\text{N}$ ,  $m$ .  $64-6^\circ$ , which is probably a di-Et homu-acridinate; sapon. gives 2-methylquinoline-3-carboxylic acid, it being impossible to isolate the di- $\text{CO}_2\text{H}$  acid. **I** (1.7 g.) and 2.2 g.  $\text{AcCH}_2\text{COCO}_2\text{Et}$  in  $\text{EtOH}$ , condensed with a little  $\text{KOH}$ , give 1.5 g. of the compd.,  $\text{C}_{14}\text{H}_{13}\text{O}_3\text{N}$ ,  $m$ .  $92-3^\circ$ . Alk. sapon gives an acid,  $\text{C}_{12}\text{H}_9\text{O}_3\text{N}$ ,  $m$ .  $141^\circ$  (decompn.), which, heated at its  $m$ . p. *in vacuo*, splits off  $\text{CO}_2$  and gives the compd.  $\text{C}_{11}\text{H}_9\text{ON}$ ,  $m$ .  $100-1^\circ$ ,  $b_d$   $182^\circ$  (phenylhydrazone,  $m$ .  $165-6^\circ$ ; oxime,  $m$ .  $206-7^\circ$ ); oxidation with  $\text{CrO}_3$  in  $\text{H}_2\text{SO}_4$  gives 3-quinolinecarboxylic acid, condensation with  $\text{BzH}$  gives the compd.  $\text{C}_{18}\text{H}_{13}\text{ON}$ ,  $m$ .  $223-4^\circ$ . 2,4-Dihydroxyquinoline-3-carboxylic amide, pale yellow,  $m$ .  $295^\circ$  (decompn.); heating with  $\text{POCl}_3$  in a sealed tube gives 2,4-dichloro-3-cyanoquinoline, catalytically reduced to 3-cyanoquinoline,  $m$ .  $108^\circ$ ; since the yield was poor, it was also obtained by heating the amide of 3-quinolinecarboxylic acid,  $m$ .  $195^\circ$ , with  $\text{POCl}_3$ ; this does not yield definite products with Grignard reagents. **I** and  $\text{CO}(\text{CH}_2\text{COCO}_2\text{Et})_2$  give the compd.  $\text{C}_{18}\text{H}_{17}\text{O}_4\text{N}$ ,  $m$ .  $129^\circ$ . C. J. WEST

**Action of ammonia on monobromoacetaldehyde and the preparation of pyrazine from the latter.** A. E. CHICHIBABIN AND M. N. SHCHUKINA. *Ber.* 62B, 1075-80 (1929).—Attempts to prep. pyrazine (**I**) directly from  $\text{BrCH}_2\text{CHO}$  (**II**) and  $\text{NH}_3$  did not give satisfactory results; on heating in alc. in sealed tubes, chiefly an insol resin, with only insignificant amts. of **I**, was formed. Accordingly the products formed by replacing the  $\text{Br}$  in **II** by  $\text{NH}_2$  (see below) were oxidized with  $\text{Hg}^{++}$  salts; even under these conditions the yields of **I**, based on the **II**, were not higher than 17%. The action of  $\text{NH}_3$  on **II** varies widely with the conditions; it depends not only on the temp. but also on the velocity with which the  $\text{NH}_3$  is passed in and especially on the solvent.

Under certain conditions cryst. products of definite compn. can be isolated but resinous substances are also always formed and sometimes are the chief products. The reactions probably proceed in 2 directions: (1)  $\text{NH}_3$  adds to the  $\text{C}=\text{O}$  group and the intermediate  $\text{BrCH}_2\text{CH}(\text{OH})\text{NH}_2$  loses  $\text{H}_2\text{O}$  to form  $\text{BrCH}=\text{NH}$  which polymerizes to *tribromomethylhexahydrotriazine* (III) which was isolated in 17% yield when the reaction was carried out in  $\text{C}_6\text{H}_6$  at  $10-5^\circ$ ; (2) the Br is replaced by  $\text{NH}_2$  and the resulting  $\text{BrH} \cdot \text{NH}_2\text{CH}_2\text{CHO}$  under certain conditions reacts further to form  $\text{NH}_3$  derivs. of different structures and mol. wts. in which the Br is present as  $\text{HBr}$ , *i. e.*, is pptd. quantitatively from  $\text{H}_2\text{O}$  by  $\text{AgNO}_3$ . When the reaction was carried out in  $\text{Et}_2\text{O}$  there was obtained a cryst. product whose compn. was not always const. in different expts. and which could not be further purified because of its instability, but in the majority of cases its compn. agreed quite well with the formula  $(\text{H}_2\text{NCH}_2\text{CH}=\text{NH})_3 \cdot 3\text{HBr} \cdot \text{NH}_3 \cdot 11\text{H}_2\text{O}$  (IV); in a few cases its compn. approached the formula  $(\text{H}_2\text{NCH}_2\text{CH}=\text{NH})_3 \cdot 3\text{HBr}$ ; if the passage of the  $\text{NH}_3$  through the cold  $\text{Et}_2\text{O}$  soln. was continued for a long time there was formed a thick transparent oil which, when the  $\text{NH}_3$  was stopped and the temp. was allowed to rise, boiled with evolution of  $\text{NH}_3$  and gradually crystd. to IV. With  $\text{PhNHNH}_2$  these substances gave glyoxal phenyllosazone. III decomps.  $100^\circ$ , mol wt. in  $\text{C}_6\text{H}_6$  342.3–352.4, insol. in  $\text{H}_2\text{O}$ , decmps. on boiling into  $\text{NH}_3$  and II, decmpd. into II by cold dil. acids, appreciably reduces cold  $\text{NH}_3 \cdot \text{AgNO}_3$  only on very long standing but on boiling quickly forms a Ag mirror; on standing the crystals become dull, then yellow and in 1.5–2 months change into a brown powder. C. A. R.

The relation of chemical structure to the rate of hydrolysis of ketopiperazines. I. Hydrolysis of *N*-methylketopiperazines by alkali. P. A. LEVENE, LAWRENCE W. BASS AND ROBERT E. STEIGER. *J. Biol. Chem.* 81, 697–702(1929).—Glycylglycine, glycylsarcosine and sarcosylsarcosine anhydrides are hydrolyzed very rapidly at  $\text{pH}$  13.4, the 1st most rapidly and the other 2 at a lower rate. The rate is much lower when a Me group is substituted on the  $\alpha$ -C as in *N*-methylalanylsarcosine anhydride and the effect is still more pronounced in *N*-methylvalylsarcosine anhydride. These compds. were studied to obtain data required for the interpretation of observations on the racemization of proteins by alkali. A. P. LOTHROP

Acridine. IV. Formation of diacidryl derivatives from *N*-methylacridone. KURT LEHMSTEDT AND HEINRICH HUNDERTMARK. *Ber.* 62B, 1065–7(1929); cf. C. A. 23, 3229. —Decker and Duntan obtained from *N*-methylacridone and Zn dust in  $\text{AcOH}$  a difficultly sol. yellow ppt. which they converted with boiling  $\text{HNO}_3$  into dimethyl-diacridinium dinitrate (I); they assumed that the pinacol  $[\text{MeN}(\text{C}_6\text{H}_4)_2\text{C}(\text{OH})_2]$  (II) was further reduced to the diacidrene,  $[\text{MeN}(\text{C}_6\text{H}_4)_2\text{C}]_2$  (III) which was converted by the  $\text{HNO}_3$  into the I. Ehrlich and Benda, on the other hand, found that 3,6-diamino-10-methylacridone is reduced by Zn dust and  $\text{HCl}$  to the pinacol which rearranges directly into the quaternary chloride without passing through any intermediate product analogous to III. A repetition of D. and D.'s work confirmed their results; both II and III were isolated. The course of the reaction observed by E. and B. probably depends less on the influence of the substituents than on the medium; apparently the pinacol rearranges into the quaternary salt too rapidly in the  $\text{HCl}$  to permit of the reduction of appreciable amts. to the diacidrene. II is easily obtained by making a boiling soln. of I alk. with  $\text{NaOH}$ ; D. and D.'s statement that the diacidridinium salts give no turbidity or ppt. in  $\text{H}_2\text{O}$  with alkalis holds only for low temps. and short intervals of time; at  $0^\circ$  the alk. soln. of the nitrate gradually becomes reddish brown and begins to get turbid after 1 hr. 10,10'-Dimethyl-9,9'-diacidrene (III), light yellow, melts at a very high temp., insol. in  $\text{H}_2\text{O}$ , sol. only in traces in  $\text{Et}_2\text{O}$ , alc.,  $\text{Me}_2\text{CO}$  and  $\text{C}_6\text{H}_6$ , its solns., especially in  $\text{C}_6\text{H}_5\text{N}$ , show a beautiful green fluorescence; it dissolves in hot dil.  $\text{HNO}_3$  and on cooling seps. almost quantitatively in the yellow leaflets of I. 10,10'-Dimethyl-9,9'-dihydroxy-[9,10,9',10'-tetrahydro-9,9'-diacidryl] (II), brown, m. above  $300^\circ$ , rapidly sol. in hot dil.  $\text{HCl}$  with light yellow color, gives with concd. KI the red diacidrylium diiodide, crystals with 1  $\text{H}_2\text{O}$  which they lose at  $105^\circ$ , turning brown, and reabsorb from the air. The salts of 9,9'-diacidryl are so greatly hydrolyzed by  $\text{H}_2\text{O}$  that the free base seps. Whereas acridine is easily methylated with  $\text{Me}_2\text{SO}_4$  at  $100^\circ$ , diacidryl reacts only to the extent of 30% after 10 hrs. at  $185^\circ$ . with KI it then gives the red quaternary diiodide. As the D. and D. method gives only 0.9 g. from 10 g. *N*-methylacridone, L. and H. prepd. it by heating 2 g. 9-chloroacridine with 2 g. "Naturkupper C" 2 hrs. at  $140^\circ$ ; yield, 1.2 g. C. A. R.

Some new aryliminoxy- $\gamma$ -triazidinic derivatives. I. ADRIANO OSTROGOVICH AND VITTORIA BENA MEDIAN. *Gazz. chim. ital.* 59, 181–98(1929).—A preliminary note. Previous expts. have shown (cf. O., *Gazz. chim. ital.* 39, i, 540(1909)) that  $\text{BzH}$  condenses with guanylurea (I) and with biuret in the presence of concd.  $\text{H}_2\text{SO}_4$  to form  $\gamma$ -tri-

azidinic derivs. The present paper deals with the condensation of I with *o*- (II), *m*- (III) and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO (IV) and *p*-Me<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO (V). The products were aryl-iminoxy- $\gamma$ -triazidines, showing in conjunction with the earlier work that the condensation reaction is a general one for aryl aldehydes. I let stand 2-3 days at room temp. with II in concd. H<sub>2</sub>SO<sub>4</sub>, poured into ice-water and purified with HCO<sub>2</sub>H and animal charcoal, yields *o*-nitrophenyliminoxy- $\gamma$ -triazidine sulfate, (C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>SO<sub>4</sub> (VI), m. 249-50° (decompn.), turns dark brick-red when exposed to light. Treated with NH<sub>4</sub>OH or better with concd. aq. Na<sub>2</sub>CO<sub>3</sub>, VI forms *o*-nitrophenyliminoxy- $\gamma$ -triazidine (VII), m. 208-9°, turns brown-red in light (more sensitive than VI), sol in cold aq. alk. hydroxides. *HCl salt*, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>·HCl·H<sub>2</sub>O, m. 235-6° (decompn.), its H<sub>2</sub>O of crystn. is difficult to eliminate and is readily reabsorbed. *Chloroplatinate*, (C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>·HCl)<sub>2</sub>·PtCl<sub>6</sub> (VIII), Cu-color, m. 233-4°, rapidly turns golden yellow on exposure to light. The normal salt could not be obtained, in contrast to the corresponding derivs. of III and IV. This is the 1st case of a quadrivalent Pt complex in which there are 4 mols. of a HCl salt of a base. It may have the structure [PtCl<sub>6</sub>](H·C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>4</sub>, in which Pt has the coordination no. 8, as with complexes of Mo, W and other elements. *Nitrate* of VII, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>·HNO<sub>3</sub>, m. 216-8° (decompn.) becomes carmine-red when exposed to sunlight in aq. suspension with a little HNO<sub>3</sub>, and a trace of Ag ion. *Monopicrate* of VII, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>·C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>, yellow, m. 213-5°, becomes more intensely yellow when exposed to light; dissolved in hot aq. picric acid (satd. when cold) it forms a *dipicrate*, hydrolyzes extremely easily. Hot aq. VII and AgNO<sub>3</sub> ppt. a *Ag salt*, [Ag(C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>2</sub>](NO<sub>3</sub>), m. 200° (decompn.). Aq. AgNO<sub>3</sub> added to VII in hot NH<sub>4</sub>OH, or aq. NH<sub>3</sub>·AgNO<sub>3</sub> added to hot aq. VII ppts. the *Ag salt*, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>Ag, which is the true Ag salt with the enolic structure of VII. In a similar way from I and III was obtained *m*-nitrophenyliminoxy- $\gamma$ -triazidine sulfate, m. 257-8° (decompn.), and *m*-nitrophenyliminoxy- $\gamma$ -triazidine (IX), m. 222°. Compared with VII, it is relatively insensitive to light, though it ultimately turns pale yellow. Its salts are quite stable in light and change little or not at all. *HCl salt* turns yellow at 260°, m. 268°. *Chloroplatinate* has the normal hexachloroplateate form, (C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>PtCl<sub>6</sub>, orange-yellow, m. 255-6° (decompn.). No compd. analogous to VIII was obtained. *Nitrate*, m. 250° (decompn.). *Monopicrate*, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>·C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>·H<sub>2</sub>O, canary-yellow, m. 210-11°, stable, could not be hydrolyzed. *Dipicrate*, pale yellow, very readily hydrolyzed, contains no H<sub>2</sub>O of crystn. *Complex Ag salt*, [Ag(C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>2</sub>](NO<sub>3</sub>). *Normal Ag salt*, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>Ag. Both these Ag salts were formed as before. Following the same procedure as before, I and IV form *p*-nitrophenyliminoxy- $\gamma$ -triazidine sulfate, m. 253-4° (decompn.). *p*-Nitrophenyliminoxy- $\gamma$ -triazidine, from dil. EtOH, m. 180° (decompn.). *HCl salt*, m. 250° (decompn.). *Chloroplatinate*, (C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>PtCl<sub>6</sub>, from hot water, reddish orange, m. 246-7° (decompn.). *Nitrate*, from hot water, m. 230-1° (decompn.). *Monopicrate*, dark yellow, turns darker in light, m. 212-3° (turning brown-red). *Dipicrate*, by heating the monopicrate with excess concd. alc. picric acid, yellow, is readily hydrolyzed, could not be obtained pure. *Complex Ag salt*, [Ag(C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>)<sub>2</sub>](NO<sub>3</sub>). *Normal Ag salt*, C<sub>6</sub>H<sub>5</sub>N<sub>5</sub>O<sub>3</sub>Ag. I, *p*-Me<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO and concd. H<sub>2</sub>SO<sub>4</sub> let stand 2-3 days at room temp., poured into ice-water and almost neutralized with Na<sub>2</sub>CO<sub>3</sub>, ppts. *p*-dimethylaminophenyliminoxy- $\gamma$ -triazidine sulfate, (C<sub>11</sub>H<sub>12</sub>N<sub>5</sub>O)<sub>2</sub>·H<sub>2</sub>SO<sub>4</sub> (X), m. 252-3° (decompn.), turns yellow in sunlight; heated with 2N H<sub>2</sub>SO<sub>4</sub> and cooled it ppts. another sulfate, C<sub>11</sub>H<sub>12</sub>N<sub>5</sub>O·H<sub>2</sub>SO<sub>4</sub> (XI), m. 208-10° (decompn.), not colored by sunlight, hydrolyzed on diln. with water to X. X or XI dissolved in excess concd. H<sub>2</sub>SO<sub>4</sub>, a relatively large vol. of EtOH-Et<sub>2</sub>O (equal parts) added, yields a 3rd sulfate, C<sub>11</sub>H<sub>12</sub>N<sub>5</sub>O·2H<sub>2</sub>SO<sub>4</sub> (XII), m. 120-2° to a milky liquid which becomes green at 180-90°, hydrolyzes very easily to XI and thence to X, is not colored by sunlight. Excess concd. Na<sub>2</sub>CO<sub>3</sub> added to X, XI or XII, filtered, washed with water and the residue recrystd. from boiling water or hot dil. MeOH or EtOH, yields *p*-dimethylaminophenyliminoxy- $\gamma$ -triazidine (XII), C<sub>11</sub>H<sub>12</sub>N<sub>5</sub>O·H<sub>2</sub>O, m. 220-1° (decompn.); its H<sub>2</sub>O of crystn. is eliminated *in vacuo* at 140° and is reabsorbed on contact with the atm.; it is much less sol. than VII and IX in aq. alk. hydroxides, which must be hot to dissolve it. It becomes intensely yellow in sunlight. Its hot aq. solns. are distinctly alk., which suggests that the mol. of H<sub>2</sub>O is bound to the Me<sub>2</sub>N group, forming a true NH<sub>4</sub> hydroxide. This would be the first known stable hydroxide of an org. tertiary amine. This would explain why XII gives stable non-hydrolyzable salts, even with HCO<sub>2</sub>H and AcOH, whereas its analogous compds. do not. *Mono-HCl salt*, C<sub>11</sub>H<sub>12</sub>N<sub>5</sub>O·HCl, by evapn. of XII in 2 N HCl (calcd quantity), m. 212-4° (becoming green just below the m. p. and ruby-red just above the m. p.). XII evapd. with excess 2 N HCl and a little AcMe added to facilitate crystn. yields the *di-HCl salt*, C<sub>11</sub>H<sub>12</sub>N<sub>5</sub>O·2HCl·H<sub>2</sub>O, turns emerald-green at 180°.

in 222–3° (decompn.), also formed by passing dry HCl over dry XII. AcMe added to XII in 2 N HCl ppts. the *di-HCl salt*,  $C_{11}H_{15}N_5O \cdot HCl \cdot 2H_2O$ , m. 200° (first becoming emerald-green). A cryst. *chloroplatinate* could not be obtained, the product always being a sirup. XII dissolved in dil. HNO<sub>3</sub> and AcMe added ppts. the *nitrate*,  $C_{11}H_{15}N_5O \cdot HNO_3$ , rose-colored, m. 215° (decompn.). XII dissolved in hot dil. AcOH, and the product recrystd. from water, yields the *acetate*,  $C_{11}H_{15}N_5O \cdot AcOH$ , yellowish, m. 202–3° (decompn.). XII dissolved in dil. HCO<sub>2</sub>H yields the *formate*,  $C_{11}H_{15}N_5O \cdot HCO_2H$ , m. 213° (decompn.). Aq. picric acid (XIII) added to hot aq. XII (equimol. parts) ppts. the *mono-picrate*,  $C_{11}H_{15}N_5O \cdot C_6H_3N_3O_7$  (XIV), bright red, m. 220° (decompn.), also formed by agitating XII (moist freshly prepd. powder) with excess aq. XIII, and recrystg. from water. XIV suspended in cold satd. aq. XII is transformed into the *tri-picrate*,  $C_{11}H_{15}N_5O \cdot 3C_6H_3N_3O_7$  (XV), lemon-yellow, softens 185°, m. 190° (decompn.), is hydrolyzed in hot water to XIV. It is probable that the 1 mol. of XIII in XIV is fixed to the Me<sub>2</sub>N group, while the other 2 mols. of XIII in XV are bound to the triazidine nucleus. Besides adding 2 more mols. of XIII to form XV, XIV has the power to add other acids, *e. g.*, HCl, HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub>, forming mixed salts. All the latter are readily hydrolyzed to XIV. XIV and N HCl (calcd. quantity) let stand and the product dried, form the *picromonohydrochloride*,  $C_{11}H_{15}N_5O \cdot C_6H_3N_3O_7 \cdot HCl$  (XVI), light yellow, turns red around 130°, softens and becomes dark green at 185°, and m. 190° (decompn.). XIV and 3 N HCl let stand overnight deposit the *picrotetrahydrochloride*  $C_{11}H_{15}N_5O \cdot C_6H_3N_3O_7 \cdot 3HCl$ , (XVII), yellowish, m. 153–5° (decompn.). Kept *in vacuo* over soda lime a long time, XVII forms the *picrodihydrochloride*  $C_{11}H_{15}N_5O \cdot C_6H_3N_3O_7 \cdot 2HCl$ , yellowish, m. approx. 176° (decompn.). By hydrolysis, all 3 mols. of XIII in XV can be eliminated, XIV being formed when hot, while at ordinary temp a lemon-yellow *monopicrate* (XVIII) is formed. This monopicate contains no Cl ions, yet has the phys. properties of XVI, including its m. p., the only difference between XVI and XVIII being that XVI turns green around its m. p. The difference between XIV and XVIII is being studied. All these derivs contain in the triazidine nucleus a CO group bound to 2 NH radicals and are sol. in aq. alk. hydroxides, first passing to the acid enolic form. Nevertheless, this enolic form is stable only as metallic salts and could not be obtained in the free state, since it reverted immediately to the original CO form when its alk. solns. were neutralized with AcOH or even with CO<sub>2</sub>. Furthermore, by dissolving in hot NH<sub>4</sub>OH, the compds. are recovered unaltered on cooling, without the formation of any NH<sub>4</sub> salts. The carbimidyl group (the C atom of which is an integral part of the triazidine group) probably represents the only stable form, for Ac derivs. could not be obtained which should be formed even if the compds. were partially of the amine structure or if the seminuclear imine were to be transformed tautomerically during the reaction to the amine structure. For these reasons the compds. in the present paper are considered to be derivs. of the hypothetical sym. hexahydrotriazidine  $\gamma$ -triazidine. In virtue of the asymmetry of the triazidine nucleus, these derivs. should all be racemic and it should be possible to resolve them into optical antipodes by a suitable acid. II. Additions and corrections to the preceding note on the same subject. *Ibid* 198 200.—Further expts. on derivs. of *p*-dimethylamino-phenyliminoxy- $\gamma$ -triazidine modify certain results already obtained (*cf.* above). The picromonohydrochloride is very difficult to obtain repeatedly with the same compn., for there is a strong tendency for the reaction:  $2 C_{11}H_{15}N_5O \cdot C_6H_3N_3O_7 \cdot HCl \rightarrow C_{11}H_{15}N_5O(C_6H_3N_3O_7)_2 + C_{11}H_{15}N_5O \cdot 2HCl$ , to take place. This reaction was confirmed by quant. analysis. The di-HCl salt remains in soln., while the *dipicrate*,  $C_{11}H_{15}N_5O(C_6H_3N_3O_7)_2 \cdot 1.5H_2O$ , ppts. The latter turns red around 140°, softens around 185° and m. 190° (to a black-brown liquid). If, instead of adding a strictly equimol. quantity of HCl to the monopicate, a slight excess is added, then the dipicrate adds HCl, forming a *dipicromonohydrochloride*,  $C_{11}H_{15}N_5O(C_6H_3N_3O_7)_2 \cdot HCl$ , yellow, m. 185–90° (to a greenish brown liquid). The HCl is eliminated *in vacuo* at 100°. The yellow monopicate (*cf.* preceding abstr.) does not exist, and it was only the dipicrate. The red monopicate treated with dry HCl gas forms a *picrotetrahydrochloride*  $C_{11}H_{15}N_5O \cdot C_6H_3N_3O_7 \cdot 4HCl$ , unstable, losing HCl slowly in air. The base in high excess, subjected for a long time with aq. picric acid forms a *semipicrate*,  $(C_{11}H_{15}N_5O)_2 \cdot C_6H_3N_3O_7$ , golden yellow, m. 205–6°, does not turn red when heated dry or in water. C. C. D.

**Alkaloid of *Stemona japonica*.** I. K. SUZUKI. *J. Pharm. Soc. Japan* 49, 457–64 (1929).—Alc. exts. from the root of *Stemona japonica* in 0.01% yield stemonidine,  $C_{17}H_{27}NO_5$ , m. 116°, contains the following groups: =NH, —OMe, —CO.O— and OH. It is different from hodorine,  $C_{16}H_{21}NO_5$  (Furuya, *J. Pharm. Soc. Japan*; Sept., 1911; *cf.* C. A. 8, 550). S. proposes the formula  $C_{17}H_{21}(:NH)(OMe)(COO)(OH)_2$ .

F. I. NAKAMURA

**Synthesis of coptisine.** ERNST SPÄTH AND ROBERT POSEGA. *Ber.* 62B, 1029-33 (1929).—It was hoped that by hydrolyzing the MeO groups in palmatine chloride and treating the resulting product in alk. soln. with  $\text{CH}_2\text{I}_2$ , coptisine (I) would be formed. The amorphous product obtained in the last step, however, yielded no tetrahydrocoptisine (II). Delépine's methylene sulfate (mol. wt. detns. in  $\text{Me}_2\text{CO}$  indicate it has the formula  $(\text{CH}_3\text{SO}_4)_2$ ) gave no better results, although with  $o\text{-C}_6\text{H}_4(\text{OH})_2$ , it gives 15% of the methylene ether. Tetrahydropalmatine was then hydrolyzed with fuming  $\text{HCl}$  to the compd.  $\text{C}_{17}\text{H}_{19}\text{O}_4\text{N} \cdot \text{HCl}$  (90% yield; also obtained in the same way from tetrahydrojatrorrhizine), 3.2 g. of which, when placed with  $\text{CH}_2\text{Cl}_2$ ,  $\text{NaOMe}$  and  $\text{MeOH}$  in a bomb at  $-80^\circ$ , evacuated to 1 mm., sealed and heated 6 hrs. at  $100^\circ$ , the operation being repeated after addn. of fresh  $\text{CH}_2\text{Cl}_2$  and  $\text{NaOMe}$ , gave 0.06 g. II, m.  $228-9^\circ$  (evacuated tubes); Kitasato found  $217-8^\circ$  in open tubes. The II was identical with a product obtained from protopine converted with  $\text{Na-Hg}$  into the carbinol base, then into the quaternary iodide with  $\text{NaI}$  and distd. in a high vacuum to split off  $\text{MeI}$ . C. A. R.

**Carnegine.** ERNST SPÄTH (IN PART WITH JOSEF PASSL). *Ber.* 62B, 1021-4 (1929).—1-Methyl-6,7-dimethoxy-3,4-dihydroisoquinoline (I), prepd. from 3,4-( $\text{MeO}$ ) $_2\text{C}_6\text{H}_3\text{CH}_2\text{NHAc}$  and  $\text{P}_2\text{O}_5$ , in boiling  $\text{PhMe}$  (C. A. 23, 2443), yields with  $\text{MeI}$  at  $100^\circ$  a *methiodide*, crystals with 3  $\text{H}_2\text{O}$ , m.  $100-2^\circ$  and anhyd.,  $176-8^\circ$ , which is reduced by  $\text{Sn}$  and  $\text{HCl}$  to the *tetrahydroisoquinoline* (II), identical with Heyl's carnegine (C. A. 23, 1211). II is a thick oil, b.  $170^\circ$  (bath temp.):  $\text{HCl}$  salt, m.  $210-1^\circ$ ; *picrate*, m.  $212-3^\circ$  (decompn.) in an evacuated capillary; *2,4,6-trinitro-1,3-cresolate*, m.  $169-70^\circ$  (evacuated tube); *methiodide*, m.  $210-1^\circ$  (vacuum tube). The identity of the synthetic and natural substances was proved by mixed m. p. detns. on the above derivs. Furthermore, that I and II are the 1-methyl-6,7-dimethoxy derivs. and not the 1,7,8-isomers, as would be the case if, in the prepn. of I, the ring had closed in the  $o$ -position to 1 of the  $\text{MeO}$  groups, is shown by the fact that oxidation of I with  $\text{KMnO}_4$  gives *m*- and not ordinary hemipinic acid. It is worthy of note that natural II, like the peltoline in *Anhalonium williamsi*, is optically inactive. C. A. R.

**Constitution of isochondodendrine.** III. FRANZ FALTIS AND KAROLINE ZWERINA (WITH A. B. GAHLIB ATTIA). *Ber.* 62B, 1034-41 (1929); cf. C. A. 22, 1777.—It was shown in the 2nd paper that the tri- $\text{CO}_2\text{H}$  acid formed by oxidation of the compd  $\text{C}_{18}\text{H}_{16}\text{O}_8$  which is obtained by Hofmann degradation of isochondodendrine (I) is 1,2,3,4-(or 6), 5-( $p\text{-HO}_2\text{CC}_6\text{H}_4$ )( $\text{MeO}$ ) $_2\text{C}_6\text{H}(\text{CO}_2\text{H})_2$  (II); whether one of the  $\text{CO}_2\text{H}$  groups is in position 4 or 6 will have to be detd. by synthesis. For methylisochondodendrine, whose constitution had been completely established except for the point of union of the phenyl ether O with nucleus I, the formula was accepted as almost certain, for union through C atom 6, i. e., in the  $o$ -position to the two-C atom bridge, seems very improbable on sterical grounds. If the above formula is correct, oxidation should give a II with a  $\text{CO}_2\text{H}$  group in the 4-position. 3,4-Dimethoxy-1,1'-diphenylether-5,6,4'- (III) and -5,6,3'-tricarboxylic acid (IV) have been synthesized by condensation of the di-Me ester of 6-bromohemipinic acid (V) with the Na salts of *p*- and *m*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{Me}$ , whereby it has for the first time been proven that II cannot be derived from hydroxyhydroquinone. No condensation with *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{Me}$  could be effected.

Bromoopianic acid, m.  $204^\circ$ , obtained in 90% yield from opianic acid in  $\text{H}_2\text{O}$  at  $60-70^\circ$  slowly treated with a 2-3 fold excess of  $\text{Br}$ , gives on cautious heating in 80%  $\text{MeOH}$  with 1 mol.  $\text{NH}_4\text{OH} \cdot \text{HCl}$  90% of bromoopianoxime anhydride which, when boiled several hrs. in 100 parts  $\text{H}_2\text{O}$ , yields the acid  $\text{NH}_4$  salt of V, and after filtering the imide of V, addn. of  $\text{HCl}$  and concn. gives the *anhydride* of V, m.  $193^\circ$ , dissolving in hot  $\text{H}_2\text{O}$  as the acid and stable toward concd.  $\text{H}_2\text{SO}_4$  at room temp.; slowly treated alternately with  $\text{Me}_2\text{SO}_4$  and 20%  $\text{KOH}$  it yields 59% of the *di-Me ester*, m.  $56-7^\circ$ . *Tri-Me ester* of III (56% from the ester of IV, *p*- $\text{KOC}_6\text{H}_4\text{CO}_2\text{Me}$ , "Naturkuper C" and  $\text{Cu}(\text{OAc})_2$  at  $150-70^\circ$ ), m.  $108-9^\circ$ , is different from the tri-Me ester of II whose m. p. ( $99-102^\circ$ ) it depresses to  $82^\circ$ . Free III, m.  $242^\circ$  (decompn.), gives a flocculent orange-yellow ppt. with  $\text{FeCl}_3$ , seps. with 2  $\text{H}_2\text{O}$  and changes into the anhydride above  $100^\circ$ . *Tri-Me ester* of IV (yield 70%), resin partly crystg. when rubbed with  $\text{MeOH}$ ; m.  $111-2^\circ$ , depresses the m. p. of the ester of IV  $8^\circ$ ; free IV sinters  $177^\circ$ , m.  $179-83^\circ$  on slow,  $185^\circ$  (decompn.) on rapid heating, shows no tendency to anhydride formation, gives an orange-yellow ppt. with  $\text{FeCl}_3$ , depresses the m. p. of III. III when demethylated with boiling  $\text{HI}$  loses a  $\text{CO}_2\text{H}$  group; the *nor-acid*,  $\text{C}_{14}\text{H}_{10}\text{O}_7$ , is a powder, m. above  $250^\circ$  (decompn.), gradually turns brown in the air, gives with  $\text{NH}_4\text{OH}$  a pink color

turning to green on boiling, with very dil.  $\text{FeCl}_3$  a transient light blue color, with dil.  $\text{Na}_2\text{CO}_3$  a violet-red color changing to fiery red, with very dil.  $\text{HCl}$  a violet color changing to blue with pptn. of a dark ppt. The *nor-acid* from IV, yellow powder, m.  $248^\circ$  (decompn.). C. A. R.

**4,5-Dimethoxyhemimellitic acid.** FRANZ FALTIS AND FRITZ KLOIBER. *Ber.* 62B, 1041-5(1929).—4,5-Dimethoxyhemimellitic acid (I) has been obtained by replacing the diazo group in diazohemipinic acid (II) by CN and, without isolating the nitrile, hydrolyzing with  $\text{HCl}$ . Under the proper conditions (by using the K salt obtained by cautious neutralization of II with 1 mol.  $\text{KOH}$ ), I is obtained in quite good yield as the sole product of the reaction; otherwise there is also obtained 5,2,3- $\text{HO}(\text{MeO})_2\text{-C}_6\text{H}_3\text{CO}_2\text{H}$ . I agrees in its properties in general with Gorter's description (*C. A.* 16, 2470), except that the Ca salt has 5 instead of 3 mols.  $\text{H}_2\text{O}$ . The transformation into methemipinic anhydride (III) is also not so simple in working with larger amts. because of the volatility of an *anhydride acid*,  $\text{HO}_2\text{C}(\text{MeO})_2\text{C}_6\text{H}(\text{CO})_2\text{O}$  (IV), m.  $180^\circ$ , which I forms at  $120\text{--}30^\circ$ . *In vacuo* at  $240\text{--}50^\circ$  IV distills over slowly but almost completely and when  $\text{CO}_2$  is passed over I at  $250^\circ$  some of the IV deposits entirely undecompd. in the cold part of the tube; only by brisk heating to  $300\text{--}20^\circ$  and subsequent vacuum distn. can a mixt. contg. III, along with IV, be obtained. IV dissolves in  $\text{Na}_2\text{CO}_3$  with green fluorescence which disappears within 0.5 hr. as the IV is hydrated to I; in  $\text{NaOH}$  the disappearance of the fluorescence is very rapid, in  $\text{NaOAc}$  it is considerably slower. With  $\text{CH}_3\text{N}_2$  I gives a tri-Me ester, m.  $86\text{--}7^\circ$ , whose identity with an oily ester obtained from the oxidation product of laurotetanine was shown by the fact that the oil crystd. when seeded with the synthetic compd. and the 2 substances did not depress each other's m. p. C. A. R.

**A synthesis of *rac*-corydalines.** ERNEST SPÄTH AND ERICH KRUTA. *Ber.* 62B, 1024-9(1929).—One of the arguments against the plausible assumption that the berberine-like bases are formed in plants from derivs. of tetrahydropapaverine (I) by condensation with  $\text{HCHO}$  was the fact that in the reaction between I and  $\text{HCHO}$  the ring is not closed in the *o*- but in the *p*-position to 1 of the  $\text{MeO}$  groups, giving norcorydaline (II) instead of tetrahydropalmatine (III). Recently, however, it was shown (*C. A.* 23, 1644) that if the  $\text{MeO}$  groups in I are sapond. before the treatment with  $\text{HCHO}$  and the product is then methylated with  $\text{CH}_3\text{N}_2$  there are obtained both II and III. This method has now been applied to the synthesis of the *rac*-corydalines (IV). Methylpapaverine, obtained by condensing papaverine with 40%  $\text{HCHO}$  at  $125^\circ$  and reducing the resulting methylene deriv. with Pd-charcoal, gives on elec. reduction at a Pb cathode in 25%  $\text{H}_2\text{SO}_4$  the *py-tetrahydro deriv.* (V), probably a mixt. of the 2 possible *rac*-bases, about 0.5 of which was obtained as a *cryst. hydrate*,  $2\text{C}_{21}\text{H}_{27}\text{O}_4\text{N}_2\cdot\text{H}_2\text{O}$ , m.  $93\text{--}5^\circ$  (evacuated tubes); *picrate*, orange-yellow, m.  $215\text{--}6^\circ$  (decompn) in evacuated tubes; *N-Bz deriv.*, amorphous, non-basic. The  $\text{MeO}$  groups in the crude V were sapond. with fuming  $\text{HCl}$  at  $150\text{--}5^\circ$  and the resulting *compd.*,  $\text{C}_{17}\text{H}_{19}\text{O}_4\text{N}_2\cdot\text{HCl}$ , m.  $238\text{--}40^\circ$  (evacuated tubes), was condensed with  $\text{HCHO}$  and methylated with  $\text{CH}_3\text{N}_2$ ; yield of methylated product (VI), about 10%. The sepn. of the components of VI presented difficulties. Crystn. from a little  $\text{Et}_2\text{O}$  at  $0^\circ$  yielded pure *ms*-corydaline (about 10% of the VI). The tertiary were sepd. from the other bases by conversion with hot alc. I into the yellow quaternary iodides which were reduced by Zn and  $\text{AcOH}$  to the more easily separable tetrahydro bases; fractional pptn. of the acid solns. of these bases with  $\text{KBr}$  gave ppts. from which a small amt. of IV was isolated. These results indicate that plants probably manuf. the berberine-like bases not from completely methylated but from wholly or partially demethylated bases C. A. R.

**Alkaloid of *Lycoris radiata*.** III. H. KONDO AND K. TOMIMURA. *Imp. Univ. Tokyo. J. Pharm. Soc. Japan* 49, 438-44(1929).—In a previous publication (cf. *C. A.* 22, 2948) it was reported that the root of *Lycoris radiata* contains lycorine and sekisanine. K. and T. extd. new compds. and named them sekisanoline (I) and homolycorine (II), resp. I,  $\text{C}_{19}\text{H}_{21}\text{NO}_6$ , decomp.  $152^\circ$ , sol. in ordinary org. solvents,  $[\alpha]_D^{25} -60.27^\circ$  in  $\text{CHCl}_3$ . Sekisanoline-MeI decomp.  $117\text{--}22^\circ$  and corresponds to  $\text{C}_{19}\text{H}_{21}\text{NO}_6\cdot\text{MeI}$ . I contains neither  $\text{OMe}$  nor  $\text{NMe}_2$  groups. It gives a positive Gaebler reaction and contains a  $\text{CH}_2\text{O}_2$  group. The Pt salt and picrate decomp.  $211^\circ$  and  $127\text{--}33^\circ$ , resp. Acetylsekisanoline decomp.  $155^\circ$  and corresponds to  $\text{C}_{19}\text{H}_{21}\text{NO}_6\cdot(\text{COMe})_2$ . I contains 2 phenolic OH groups and the N is of tertiary nature. II,  $\text{C}_{19}\text{H}_{21}\text{NO}_4$ , m.  $175^\circ$ ,  $[\alpha]_D^{25} 65.10^\circ$  in alc. II forms many salts:  $\text{HCl}$  salt, Pt salt, picrate and methiodide decomp.  $285^\circ$ ,  $267^\circ$ ,  $268^\circ$  and  $256^\circ$ , resp. II has no phenolic OH, but contains 2  $\text{OMe}$  groups. The N is of tertiary nature. The di-Ac deriv. decomp.

173° and corresponds to  $C_{17}H_{21}NO_4(OMe)_2$ . K. and T. propose the structures  $C_{17}H_{19}O_4(O_2CH_2)(OH)_2(:N)$  and  $C_{17}H_{19}(OMe)_2(OH)_2(:N)$  for I and II, resp. F. I. N

**Solanine.** GIUSEPPE ODDO. *Gazz. chim. ital.* 59, 155-60(1929).—See C. A. 23, 2978. C. C. DAVIS

**Synthetic morphine.** OTAKAR WEBER. *Chem. Listy* 23, 79-81(1929).—Synthetic morphine was prepd. according to recent methods on a lab. scale. It was recrystd. from EtOH yielding brilliant prismatic needles; morphine from a vegetable source was also recrystd. from EtOH and used as a control. Fröhde's reagent (0.1 g Na molybdate in 10 cc. concd.  $H_2SO_4$ ) gives the same color reaction with morphine from both sources and with mixts. of both kinds of morphine. Concd.  $H_2SO_4$  dissolves the morphine of both sources and forms a colorless soln. Concd.  $HNO_3$  dissolves the morphine (synthetic) forming a blood-red soln. which becomes yellow gradually, the addn. of  $ZnCl_2$  converts the yellow color to a violet. Synthetic morphine in concd.  $H_2SO_4$  was heated for 10 min. and, after cooling, the addn. of  $HNO_3$  produced a red color. Both varieties of morphine responded identically to Marquis' reagent ( $HClO$  -  $H_2SO_4$  mixt.). With  $Me_2NC_6H_4CHO$  in  $H_2SO_4$ , the synthetic morphine yielded an immediate clear red color; the natural morphine gave a faint color which is due to a contamination by other alkaloids. Morphine from both sources had no definite m. p. and began to decomp. 230°. Synthetic morphine prepd. according to McLang is 99-99.5% pure and can be used in prepg. morphine-HCl directly without going through the di-Ac deriv. This prepn. gives all of the reactions of the HCl salt prepd. from natural morphine. Codeine from synthetic morphine is a white cryst. powder, it gives the chem. reactions of codeine from natural morphine. Synthetic morphine was acetylated according to McLang and yielded quantitatively diacetylmorphine which when recrystd. m. 171.5-2°. Ethylation of synthetic morphine yielded dionine which gives a dark blue color with Marquis' and a green color with Fröhde's reagent, and m. 123°. Apomorphine from synthetic morphine is a white amorphous powder which forms a colorless soln. in  $H_2SO_4$  and a red color with  $HNO_3$ . A mixt. of a 1% soln. of apomorphine, 4 drops 0.3%  $K_2Cr_2O_7$ , and 10 cc.  $AcOEt$  yielded a violet color which turned green after adding  $ZnCl_2$ . Attempts are being made to produce synthetic morphine on a semicommercial scale. The pharmacol. studies are to be made

FRANK MARESH

**The amine oxides of hydrastine and of narcotine.** MAX POLONOVSKI and MICHEL POLONOVSKI. *Compt. rend.* 188, 341-3(1929).—Hydrastine (I) treated in cold  $AcOH$  with 30%  $H_2O_2$  for several days and neutralized with  $Na_2CO_3$  yielded a pasty ppt. which when washed with satd.  $AcONa$  gave a slightly colored honey-like mass, very sol. in  $H_2O$ , EtOH,  $Me_2CO$  and  $CHCl_3$ . Evapn. *in vacuo* left the amine oxide (II) of I, a white substance,  $\alpha_D$  88° (3% in  $CHCl_3$ ), which reacts with  $SO_2$  in  $H_2O$  or  $CHCl_3$  to form a sulfuric ether, reddened by heating and converted by boiling with  $H_2O$  to I sulfate. II heated with  $Ac_2O$  gives a strong red which is characteristic of amine oxides. It forms a HCl salt, m. about 125°,  $\alpha_D$  160° (12% in  $H_2O$ ), sol. in  $H_2O$ ,  $Me_2CO$ , less sol. in abs. EtOH; *picrate*, amorphous, m. 128°. II is very unstable even at ordinary temps. and on heating it assumes a yellow form, neutral to litmus, insol. in  $H_2O$ , very slightly sol. in EtOH and  $Me_2CO$ , and possessing no optical activity. This new product (empirical formula,  $C_{20}H_{19}O_7NCH_3$ ), m. 189°, lacks all the properties of an amine oxide. It is not reduced by  $SO_2$  and gives no red color with  $Ac_2O$ . It forms a HCl salt, m. 196°. Narcotine (III) subjected to the treatment outlined yields an amine oxide (IV) of vitreous consistency, very sol. in  $H_2O$ , EtOH and  $CHCl_3$ ,  $\alpha_D$  135° (in  $CHCl_3$ ), easily reduced by  $SO_2$  to the original III. IV gives the characteristic red color with  $Ac_2O$  and forms well crystd. salts with dil. acids. IV.HCl, m. 195°,  $\alpha_D$  100°, is very sol. in  $H_2O$ ; *picrate*, m. 130°; *chloroplatinate*, m. 175°. IV readily changes into a compd., m. 228-9°, with the same soly. behavior as that resulting from II and similarly possessing no optical activity. This transformation product is identical with that described by Drummond and McMillan (C. A. 21, 247) save for its optical activity which is ascribed to IV which escaped these observers. C. H. PERR

**The preparation of active sandaraco-pimaric acid and its derivatives.** FR. BALÁŠ AND J. BRZÁK. *Collection Czechoslov. Chem. Comm.* 1, 306-14(1929).—The isolation of pure cryst., optically active natural sandaraco-pimaric acid,  $C_{20}H_{30}O_2$ , from sandarac in 0.7% yield is described. The properties, including crystallographic detns. of the acid, its Na, K,  $NH_4$ , Ag, di- $\delta$ -amylamine, piperidine and cinchonidine salts and its Me and Et esters are given. It m. 173°,  $[\alpha]_D$  -18.8° in 1.6% alc. soln. and -13.0° in 1.6%  $CHCl_3$  soln. V. F. HARRINGTON

**The digitalis glucosides. III. Gitoxigenin and isogitoxigenin.** WALTER A. JACOBS AND EDWIN L. GUSTUS. *J. Biol. Chem.* 82, 403-9(1929); cf. C. A. 23, 149 -

Facts now available show that isogitoxigenin (I) like the other iso-compds., is a lactone or the lactol form of a hydroxyaldehyde. I when sapond. displays great stability towards alkalis. Me isogitoxigenonate ( $C_{24}H_{34}O_6$ ) consumes only 1 equiv. of 0.1 N alkali when sapond. by the method which opened both ester and lactone groups. With stronger alkali and higher temp., it is now possible to detect the presence of a relatively resistant lactone group. This ester is therefore a ketolactone ester. Iso-gitoxigeninic acid upon oxidation with hypobromite yields isogitoxigenic acid ( $C_{28}H_{34}O_6$ , but formerly reported as  $C_{21}H_{30}O_6$ ), a lactone isomeric with isoperiplogenic and isosarmentogenic acids. Gitoxigenin (II) possesses 1 secondary alc. group and a tertiary HO which is presumably  $\gamma$  to the aldehydic C. The retention of the secondary HO in I is shown by its oxidation to the lactone, isogitoxigenone. It is assumed that differences in chem. properties of II and digitoxigenin are due to the position of the extra tertiary HO of II. It is definitely concluded that II, like digitoxigenin, is a tetracyclic  $\Delta^{\beta,\gamma}$ -lactone in which a C atom presumably  $\gamma$  to the lactone  $\gamma$ -C atom carries a tertiary HO group.

RUSSELL C. ERB

**Conversion of chlorophyll derivatives into phylloerythrin.** HANS FISCHER AND RUDOLF BÄUMLER. *Sitzb. math.-naturw. Abt. bayer. Akad. Wiss. München* 1929, 77-83.—The energetic alk. decompn. of chlorophyll leading to porphyrins is drastic and at best gives but a 30% yield. Enzymic means seem more attractive. When tried with pheophorbide a (I), chlorine (II), and pheophytin (III), the results were disappointing and unexpected as expts. by others have indicated that in the digestive tract of ruminants, enzymes split MeOH and phytol from chlorophyll. Since reduction goes on in the alimentary tract enzymically, chem. reducing agents, such as Na-Hg, Zn and HOAc, HI and HOAc, were employed. I and II in ether with 2% Na-Hg and NaOH, for from 11 to 18 hrs., became colorless, because of the presence of leuco compds.; on reoxidation by a stream of air, the red color was restored. The yield was very poor as only traces of porphyrins could be detected. I with Zn and HOAc gave a leuco compd. and oxidation of it produced a porphyrin. In contrast to the leuco compd., this is very sol. in pyridine. This product is phylloerythrin and is different from the porphyrin from the b component. The best results were obtained when I was heated for 7 min. at 100° with HOAc and HI (d. 1.69). The porphyrin, *i. e.*, phylloerythrin, was easily isolated by crystn. Its identity was established by the formation of a *mono-Me ester*, m. 260° (cor.), alone and when mixed with an authentic sample. A *second porphyrin*, in lesser amt., accompanied the above, and while the analysis  $C_{33}H_{36}N_4O_6$  is the same, the absorption spectrum is further toward the violet. III and Et chlorophyllide, subjected to similar treatment, behaved as did I. II by mold action gave a new porphyrin.

G ALBERT HILL

**Porphyrin synthesis. XXIII. Syntheses of coproporphyrin III and IV; a contribution to the knowledge of porphyria.** H. FISCHER, K. PLATZ AND K. MORGENROTH. *Z. physiol. Chem.* 182, 265-88(1929); cf. *C. A.* 23, 2184.—Four isomeric coproporphyrins are theoretically possible, depending on the location of the four Me and the four  $CH_2CO_2H$  groups (A) around the porphin nucleus.

These group arrangements are as follows:

Coproporphyrin	Methyls	Acid groups
I	1,3,5,7	2,4,6,8
II	1,4,5,8	2,3,6,7
III	1,3,5,8	2,4,6,7
IV	1,4,6,7	2,3,5,8

Other arrangements are not possible if each pyrrole ring carries both substituents and the porphin structure is to remain intact, which seems probable from the fact that after reduction of porphyrins to their leuco compds. oxidation gives back the original

porphyrins. I and II have already been synthesized. I is the natural coproporphyrin which occurs in porphyria and in yeast. The structure represented by III is present in hemin. The natural coproporphyrin cannot therefore be derived from the blood pigment but must be formed by a primary synthesis. The 4 coproporphyrins are readily distinguished by the sharp m. ps. of their esters. Physiologically they are of great interest because of the possibility that pathological conditions might give rise to other forms than the commonly occurring I. The syntheses were performed by succinic acid fusions of the appropriately substituted dipyrromethenes. The 1st prepn. of coproporphyrin IV were obtained from di[2,5-dimethyl-3-carboxyethylpyrryl]methene-HBr and di[2-bromo-3-methyl-4-carboxyethylpyrryl]methene-HBr by the succinic acid method and also by means of HBr-AcOH in a sealed tube. Both procedures gave poor yields. Better yields were obtained by the succinic acid fusion of di[2-bromomethyl-3-carboxyethyl-4-methylpyrryl]methene-HBr with di[2-bromo-3-methyl-4-carboxyethylpyrryl]methene HBr. The evolution of HBr begins at 150° and reaches its max. at 175-80°. The HCl ext. of the reaction mixt. has an intense bluish red color. Esterification by the usual procedure gives a tetra-Me ester, m. 168-9°. Spectroscopically the product is identical with the other coproporphyrins. The tetra-Et ester, prepd. by treatment of the free porphyrin with EtOH and HCl, m. 152°. Complex Cu salt of the tetra-Me ester, m. 216-7°; of the tetra-Et ester, m. 180-1°. The corresponding hemin was prepd. by treatment of the Me ester with AcOH and Fe, whereby the color changed from red to brown, and the product crystd from AcOH. For the prepn. of coproporphyrin III the aldehyde of hemopyrrolecarboxylic acid was required. This was obtained by suspending the acid in  $\text{CHCl}_3$ , adding HCN and satg. with HCl, then sapon. with NaOH the imine-HCl which crystd. out. The product m. 155° (semicarbazone, m. 190°; oxime, m. 152°; Me ester, m. 89°). The aldehyde was condensed with cryptopyrrole by means of HBr to 49% [4,5-dimethyl-3-carboxyethylpyrryl][5',3'-dimethyl-4'-ethylpyrrolenyl]methene-HBr, which decomp. 217°. In the same manner the Me ester of the aldehyde acid was condensed with cryptopyrrolecarboxylic acid to yield 80% of [4,5-dimethyl-3-carbomethoxyethylpyrryl][5',3'-dimethyl-4'-carboxyethylpyrrolenyl]methene-HBr, m. 138°. The latter when heated with di[2-bromo-3-methyl-4-carboxyethylpyrryl]methene yielded coproporphyrin III, which was isolated in the form of its cryst. ester. This ester exists in 2 isomorphic modifications, m. 145° and 172°, the higher-melting form being the more stable. Of considerable biol. interest is the fact that this synthetic coproporphyrin III is identical with the coproporphyrin recently isolated by Hijmans van den Bergh, Regniers and Muller (*Arch. Verdauungs-krankheiten* 42, 306) from the urine and feces of a case of congenital porphyria. It is not necessary to assume here a secondary synthesis from normal blood pigment. Coproporphyrin III and protoporphyrin are so closely related that the former could result from a simple addn. of  $\text{CH}_2\text{O}_2$  to the latter. This mode of formation is considered more probable than a primary biol. synthesis such as occurs in the formation of coproporphyrin I.

A. W. DOX

**The rate of hydrolysis of ribonucleotides.** P. A. LEVENE AND ERIK JORPES. *J Biol. Chem.* 81, 575-80(1929).—The rate of hydrolysis of the base from pyrimidine-nucleosides can be enhanced by hydrogenation of the base, hence hydrogenated cytidine-phosphoric acid was used in the expts. It behaves exactly like the purine-nucleotides not only with respect to the rate of hydrolysis of the base but also of the  $\text{H}_3\text{PO}_4$ . "The earlier conclusion, therefore, as to the allocation of the  $\text{H}_3\text{PO}_4$  in the pyrimidine-nucleotides has to be abandoned in favor of the view that the  $\text{H}_3\text{PO}_4$  in these nucleotides as well as in the purine-nucleotides is allocated on a secondary C atom." Guanylic acid derived from the pancreas gland behaves like adenylic acid derived from yeast-nucleic acid rather than like inosinic acid on hydrolysis so that it is evident that not all ribomononucleotides occurring in animal tissues are derived from an identical phosphoribose.

A. P. LOTHIROP

**The molecular binding power of bile acids and sterols.** HEINRICH RHEINBOLDT. II. Hyodesoxycholic acid. ALBERT LAUBER. *Z. physiol. Chem.* 182, 251-4(1929), cf. C. A. 23, 1906.—Hyodesoxycholic acid differs from the isomeric desoxycholic acid in its inability to form choleic acids. Further proof of this fact is now presented in thawing point and m. p. diagrams of binary systems contg. hyodesoxycholic acid with palmitic, stearic, stearolic, brassidic and behenolic acids and cetyl alc. In all cases the eutectic point was reached with 1% of the hyodesoxycholic acid. III. Cholic acid. ALBERT LAUBER. *Ibid* 255-8.—Similar diagrams for mixts. of the above fatty acids with cholic acid showed that the latter likewise fails to form mol. compds. with fatty acids. The eutectic point was invariably obtained with the mixt. contg. only 1% of the higher-melting component.

A. W. DOX

**Isoquinoline derivs. I. The synthesis of 6-methoxy-7-ethoxy-3,4-dihydroisoquinoline and its derivatives.** KONDO AND S. TANAKA. *J. Pharm. Soc. Japan* 49, 59-64 (1929); cf. *C. A.* 23, 2979.—Heating 3-methoxy-4-ethoxy-1-( $\beta$ -aminoethyl)benzene with  $\text{HCO}_2\text{H}$  at 180–200° gave, after recrystn. in alc., *N*-(3-methoxy-4-ethoxyphenethyl)-formamide (I), m. 86.5°. Heating of I, toluene and  $\text{POCl}_3$  at 105° gave colorless crystals of 6-methoxy-7-ethoxy-3,4-dihydroisoquinoline,  $\text{C}_{12}\text{H}_{15}\text{O}_3\text{N}$  (II), m. 86–7°. II forms many salts: *HCl* salt, decomp. 202°; chloroplatinate, decomp. 202°. Catalytic reduction of II.HCl in water with 1%  $\text{PdCl}_2$  soln. and active C (after 1.5 hrs. 1 g. takes up about 90 cc. H) gave 6-methoxy-7-ethoxytetrahydroisoquinoline (III); *HCl* salt, m. 206–7°. The methochloride of II as above, gave *N*-methyl-6-methoxy-7-ethoxytetrahydroisoquinoline (m. 64–4.5°). *HCl* salt, m. 227–8°. F. I. NAKAMURA

**Addition of antimony trichloride and tin tetrachloride to unsaturated hydrocarbons.** HANS VON EULER AND HARRY HELLSTRÖM. *Svensk Kem. Tids.* 41, 11–5 (1929). (In German.)—Many cases are cited in which  $\text{SbCl}_3$ ,  $\text{SnCl}_4$ ,  $\text{AsCl}_3$  and  $\text{TiCl}_3$  react with conjugated double bonds in org. compds. giving colored products. Some spectrometric data are included. Diergosteryl phosphate and  $\text{SnCl}_4$  are brought together in  $\text{CHCl}_3$  soln. and a green fluorescence results, becoming violet and again green on diln. There is at first absorption at  $434\mu$  and in the later diln. at  $620\mu$ . This is the explanation of the Carr-Price color reaction for vitamin AH since this reaction is identical with carotoid (*C. A.* 23, 3009, 3013). A. R. ROSE

**X-ray contributions to the problem of polymerization (CLARK) 2.** Configuration of quadrivalent atoms (LOWRY) 2. Comparative studies on the breakdown of polypeptides, their derivatives, and amides by normal alkali, erepsin and trypsin or trypsin-kinase (ABDERHALDEN, ZEISSET) 11A. Further comparative studies on the breakdown of polypeptides and their derivatives at various H-ion concentrations and by erepsin and trypsin-kinase (ABDERHALDEN, SCHMITZ) 11A. The problem of specific relations of erepsin and trypsin to definite atomic groupings in polypeptides (ABDERHALDEN, HERRMANN) 11A. The determination of the alkali-combining quantity of the most important sugars (HIRSCH, SCHLAGS) 2. Molecular dimensions of organic compounds (LOWRY, NASINI) 2. COLES, L. A.: **An Introduction to Modern Organic Chemistry.** London: Longmans, Green and Co., Ltd. 438 pp. 7s. 6d.

RODRIGUEZ, L. INÉS: **Estudio sobre la ionona y productos intermedios.** Santiago: Escuela tip. salesiana "La Gratitude nacional." 25 pp.

ROESLER, PAUL: **Contribution a l'etude des benzothiadiazole.** STRASSBURG: Editions universitaires. 83 pp.

**Organic bases.** I. G. FARBENIND. A.-G. Brit. 302,939, Dec. 23, 1927. In producing org. bases by the catalytic treatment of mixts. of  $\text{C}_2\text{H}_2$  with  $\text{NH}_3$  or org. bases, as described in Brit. 283,163 (*C. A.* 22, 3892) and Brit. 296,423 (*C. A.* 23, 2722) and Brit. 269,423, the mixt. leaving the catalytic chamber is washed with the condensation products formed in the reaction (or with selected fractions of the condensate), preferably at a temp. below 0°. The washing may be in 2 stages, first with fractions b. above 100° to recover the bases and then with fractions b. below 120° to recover  $\text{C}_2\text{H}_2$  from the waste gas which is mainly H. Cf. *C. A.* 23, 2185.

**Reducing organic compounds.** DONALD G. ROGERS (to National Aniline & Chemical Co.). U. S. 1,721,319, July 16. In the production of a leuco deriv. from indigo or in similar reductions, the compd. to be reduced is mixed with Zn and a soln. of  $\text{NaHSO}_4$ , the quantity of  $\text{NaHSO}_4$  used being insufficient to interact with all the Zn present, and during the reaction there is continuously added a quantity of  $\text{H}_2\text{SO}_4$  sufficient to form and maintain the presence of  $\text{NaHSO}_4$  from the  $\text{Na}_2\text{SO}_4$  present.

**Reducing or hydrogenating organic substances.** I. G. FARBENIND. A.-G. Brit. 301,577, Sept. 19, 1927. In producing  $\text{PhNH}_2$  from  $\text{PhNO}_2$  or in other reduction or hydrogenation processes, H is used under pressure in the presence of a catalyst prepd. by pptg. a metal from a soln. of its salt by means of a Si and O compd. contg. a smaller proportion of O than does  $\text{SiO}_2$ , e. g., by treating a soln. of Ni acetate with oxydisilin or

by the similar treatment of salts of metals such as Cu, Zn, Pd, Pt, Au, Sn, Ag, Co, Pb, Ti and Bi.

**Hydrogenation.** I. G. FARBENIND. A.-G. Fr. 657,179, July 9, 1928. Aromatic bases are hydrogenated by adding alkali or alk. earth compds. to the catalysts. Examples are given of the hydrogenation of PhNH<sub>2</sub> in the presence of Ni<sub>2</sub>O<sub>3</sub> contg. Na<sub>2</sub>CO<sub>3</sub> or CaO and of *o*-toluidine in the presence of CO<sub>2</sub>O<sub>3</sub> contg. CaO.

**Catalytic hydrogenation.** GRS. FÜR TEERVERWERTUNG, MEIDERICH and H. KAFFER. Brit. 302,912, Dec. 23, 1927. The residue remaining from the hydrogenation of coal by the Bergius process is used as a catalyst for the hydrogenation of hydrocarbons such as C<sub>10</sub>H<sub>8</sub> and "benzene."

**Separating gaseous or low-boiling-point hydrocarbons.** I. G. FARBENIND. A. G. Brit. 302,203, Sept. 8, 1927. Hydrocarbon mixts. such as a mixt. of ethylene, propylene, butylene and butadiene produced by decompn. of cyclohexane vapor at 600° in a quartz tube filled with Ca aluminate as described in Brit. 297,398 (C. A. 23, 2722) are liquefied and then subjected to fractional distn. under pressure. Various details are given.

**Distilling hydrocarbons, etc.** PREUSSISCHE GEWERKSCHAFT RAPHAEL. Fr. 657,413, July 2, 1928. In using molten salts or metals for distg. hydrocarbons or other substances a constant temp. is obtained by passing the molten material in a circuit successively to a heating chamber and to the treating chamber.

**Side-chain halogenation of aromatic hydrocarbons.** NIKOLAUS ZELINSKII and SCHERING-KAHLBAUM A.-G. Ger. 478,084, Nov. 29, 1923. Side-chain halogenation to the desired stage and without production of isomers is attained by conducting the halogenation in daylight or artificial light and in the vapor phase but at a temp. below the b. p. of the desired product and under such conditions that the product is immediately removed from the halogenating chamber. Thus, in prepg. C<sub>6</sub>H<sub>5</sub>CH<sub>2</sub>Cl, C<sub>6</sub>H<sub>5</sub>CHCl<sub>2</sub> may be boiled in a vessel connected with a chlorinating chamber through a reflux condenser maintained at a temp. between 110° and 176°, the arrangement being such that the C<sub>6</sub>H<sub>5</sub>CH<sub>2</sub>Cl flows back into the vessel as soon as it is formed.

**Chlorinating hydrocarbons.** HOLZVERKOHLLUNGS-INDUSTRIE A.-G. Ger. 478,083, Nov. 16, 1923. In the direct chlorination of CH<sub>4</sub> and other hydrocarbons at a high temp., the formation of HCl is avoided by addn. of O to the mixt. Diluents such as steam, CO<sub>2</sub> or N should be added also.

**Chlorinating hydrocarbons.** THE B. A. S. Co. Fr. 657,518, July 16, 1928. See U. S. 1,717,136 (C. A. 23, 3713).

**Apparatus for catalytic depolymerization of hydrocarbons.** J. MERCIER. Brit. 302,899, Dec. 22, 1927. Structural features of an app. with retorts filled with catalyst.

**Polymer of vinyl chloride.** IWAN OSTROMISLENSKY. U. S. 1,721,034, July 16. A polymerized vinyl chloride is prepd. which is sol. in PhCl and is purified from the acetone sol. polymer until it has the property of forming films of durable flexibility from its PhCl solns.

**Polymerizing diolefin hydrocarbons.** HERMANN STAUDINGER and HERMAN A. BRUSON. U. S. 1,720,929, July 16. Isoprene, indene or other diolefin hydrocarbon contg. 4 or more C atoms to the mol. is treated with a solvent such as C<sub>6</sub>H<sub>6</sub> or CHCl<sub>3</sub> and with a halide salt of Sn such as SnCl<sub>4</sub>. The product can be vulcanized like rubber.

**Diolefins.** I. G. FARBENIND. A.-G. Brit. 301,898, Dec. 9, 1927. Butadiene and its homologs are produced by passing the vapor of 1,3-butylene glycol or a homolog over acid salts such as KH<sub>2</sub>PO<sub>4</sub> or K<sub>2</sub>H<sub>2</sub>P<sub>2</sub>O<sub>7</sub> (suitably assocd. with pumice and at a temp. of about 400-10°).

**Alkyl halides.** I. G. FARBENIND. A.-G. (Karl Dachlauer and Erich Eggert, inventors). Ger. 478,126, Nov. 28, 1924. Addn. to 441,747. Alkyl halides are prepd. by passing a mixt. of an aliphatic alc. vapor with a H halide at a raised temp. over a catalyst comprising active C and H<sub>3</sub>PO<sub>4</sub>. The examples describe the prepn. of MeCl, MeBr and PrCl.

**Alkyl cyclohexanols.** SCHERING-KAHLBAUM A.-G. (Hans Jordan, inventor) Ger. 478,273, July 5, 1925. Alkyl cyclohexanols are prepd. by hydrogenating the condensation products of ketones with phenols in the presence of a catalyst until 14 atoms of H have been taken up. Examples are described.

**Alkyl phenols.** I. G. FARBENIND. A.-G. Fr. 656,908, July 2, 1928. Alkyl phenols and their hydrogenation products are obtained by treating dihydroxydiphenylmethane derivs. with H and a hydrogenation catalyst at temps. above their decompn. point. Thus, thymol may be prepd. by treating 4,4'-dimethyl-2,2'-dihydroxydiphenyldimethylmethane in this way. Several examples are given.

**Alkyl phenols.** SCHERING-KAHLBAUM A.-G. Fr. 657,293, July 11, 1928. See Brit. 294,238 (C. A. 23, 1908).

**Alkylene phenols.** SCHERING-KAHLBAUM A.-G. Fr. 657,122, July 6, 1928. 3-Methyl-6-isopropenylphenol is prepd. by heat dissocn. of 4,4'-dimethyl-2,2'-dihydroxydiphenyldimethylmethane with or without a surface catalyst such as francanite. *p*-Isopropenylphenol is obtained from 4,4'-dihydroxydiphenyldimethylmethane, and *p*-isobutenylphenol from 4,4'-dihydroxydiphenylmethylmethane.

**Alkylene oxides.** TH. GOLDSCHMIDT A.-G. Fr. 656,996, July 4, 1928. Alkylene oxides are prepd. by passing a chlorohydrin soln. and an alkali or alk. earth soln. or suspension continuously through a still by a path of great length.

**Aliphatic alcohols.** E. I. DUPONT DE NEMOURS AND CO. Fr. 657,124, July 6, 1928. In the catalytic production of alcs. from CO and H the yield of higher alcs. per unit of vol. and time is increased by increasing the flow of gases to more than 5 times the flow used for the production of MeOH, and by using catalysts favoring the formation of higher alcs., such as basic Zn-NH<sub>4</sub> chromate contg. 15% K<sub>2</sub>CrO<sub>4</sub>, or Zn chromite or ZnO contg. K<sub>2</sub>SO<sub>4</sub>.

**Esters of higher aliphatic acids.** I. G. FARBENIND. A.-G. Brit. 302,411, Sept. 22, 1927. In affecting esterifications such as those of the fatty acids from coconut oil or olive oil with glycerol, soaps of Al, Mg, Sn and Zn are used to facilitate the reaction.

**Esters of dicarboxylic acids.** I. G. FARBENIND. A.-G. Brit. 302,041, Nov. 28, 1927. Water-sol. esters are formed by acting on 1 mol. proportion of a dicarboxylic acid such as phthalic, succinic or tartaric acid with at least 2 mol. proportions of an alkylene oxide such as ethylene oxide (suitably in a diluent or solvent and in the presence of a catalyst such as alkali metal salt of hydrohalic acid). Mention is made of the use of the products as plasticizers for cellulose esters and ethers.

**Alkyl esters of abietic acid.** HERCULES POWDER CO. Fr. 656,821, June 29, 1928. Abietic acid from ordinary resin (colophany) or other resin is treated with an alkyl halide, *e. g.*, EtCl in the presence of a base such as NaOH, preferably dissolved in EtOH, to produce the corresponding ester. Cf. *C. A.* 22, 3892.

**Polysaccharide esters.** I. G. FARBENIND. A.-G. (Leo Rosenthal, inventor). Ger. 478,127, Jan. 31, 1924. Polysaccharide esters of higher fatty acids having more than 1 double bond are prepd. by treating the polysaccharide with a halide of the acid in the presence of a tertiary org. base. The products are sol. viscous liquids or masses which are readily oxidized by air. They become insol. when oxidized or when heated in an inert gas. The examples describe the prepn. of saccharose, starch and cellulose linoleates and of the starch and saccharose esters of the acids of tung oil. Cf. Brit. 239,726 (*C. A.* 20, 2167).

**Diketones and ketonic esters.** IMPERIAL CHEMICAL INDUSTRIES, LTD., and S. COFFEY. Brit. 302,750, Oct. 6, 1927. Acyl derivs. of  $\beta$ -diketones and  $\beta$ -ketonic esters are prepd. by treating an alkali metal compd. of the ketone with an org. carboxylic acid anhydride. Examples are given of the prepn. of ethyl diacetoacetate, ethyl propionylacetoacetate and ethyl butyrylacetoacetate. The C-derivs. are sepd. from the O derivs. by selective soln. of the former with dil. NaOH soln. or the like.

**Aliphatic ketones.** HOLZVERKOHLUNGS-INDUSTRIE A.-G. and K. ROKA. Brit. 302,759, Oct. 18, 1927. Aliphatic ketones are made from primary aliphatic alcs. with 2 or more C atoms in the mol. such as EtOH, from the aldehyde or aliphatic ester derivs. of these alcs. or from mixts. of these substances with each other or other derivs. such as HOAc or with inert substances, by treating the starting materials with water vapor at an elevated temp. (suitably 250–650°) in the presence of catalysts such as superficially oxidized iron with a promoter such as CaCO<sub>3</sub> or similar materials. Details for the production of acetone from acetaldehyde, etc., are given.

**Cycliketones and quinones.** I. G. FARBENIND. A.-G. Fr. 657,245, July 10, 1928. See Brit. 293,768 (*C. A.* 23, 1756).

**Diazonium salts.** I. G. FARBENIND. A.-G. Fr. 657,041, June 5, 1928. Aq. solns. of diazonium salts such as aryldiazonium fluoborates are stabilized and preserved by the addn. of acids such as HCl, AcOH, oxalic acid, fluoboric acid or polysulfonaphthalene acids, or salts having an acid reaction such as NaHSO<sub>4</sub>, K bixolate or Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>. Examples are given.

**Organic acids.** BRANDON, SIMONNOT RINUY. (Wm. J. Hale and Wm. S. Halde-man, inventors). Fr. 650,771, Mar. 12, 1928. Primary aliphatic alcs. b. below 350° are converted into the corresponding acids by passing the vapor of the alc. in contact with a reduced metal such as Cu, which removes H, and converts it into the aldehyde and then in contact with a metal oxide, *e. g.*, Cu<sub>2</sub>O<sub>3</sub> from which it takes O to form the acid. The oxide may be placed in a tower, the reduced oxide being withdrawn at the base, reoxidized and introduced at the top. An example is given of the conversion of EtOH to AcOH.

**Acids from aldoses.** FABRIQUE DE PRODUITS CHIM (VORM. SANDOZ). Fr. 656,863, June 30, 1928. Aldoses are converted to the corresponding acids by treating the sugars with Cl in alkali carbonate soln. and in the presence of small quantities of Br or I compds. In examples, lactose is converted to lactobionic acid, and glucose to gluconic acid.

**Fatty acids.** OEL- & FETT-CHEMIE G. M. B. H. Fr. 657,228, July 10, 1928. See Brit. 296,079 (C. A. 23, 2313).

**Sulfonating fatty acids.** N. V. CHEMISCHE FABRIEK "SERVO" and MEINDERT D ROZENBROEK. Fr. 657,161, July 7, 1928. See Brit. 293,690 (C. A. 23, 1765).

**Concentrating acetic and other aliphatic acids.** I. G. FARBENIND. A.-G. Brit. 302,174, Dec. 8, 1927. Aq. solns. of acetic, propionic, butyric or similar acids are extd with a solvent for the acid and an addnl. substance, *e. g.*, EtOAc with C<sub>6</sub>H<sub>6</sub>, tetrahydro naphthalene, trichloroethylene or hexahydrobenzene, or benzyl alc. with C<sub>6</sub>H<sub>6</sub>, or methylcyclohexanone with C<sub>6</sub>H<sub>6</sub>, followed by distn. of the ext. to recover the acid and solvents. Various details and modifications are described and other solvents and auxiliary substances are enumerated. Cf. C. A. 23, 3932.

**Concentrating acetic and similar acids.** H. E. MARTIN (to British Celanese, Ltd.) Brit. 301,734, Dec. 3, 1927. Dil. or waste acetic, propionic or similar acids are concd by extn. with methylene chloride (which may be mixed with ether) and then distg. the ext.

**Acetic acid and other acids from aqueous solutions.** HOLZVERKOHLEUNGS-INDUSTRIE A.-G. Brit. 302,268, Dec. 13, 1927. An aq. soln. of an acid such as HOAc is treated with a salt capable of forming a solid acid salt such as NaOAc and, without sepg the acid salt, the mixt. is subjected to distn. under reduced pressure to first obtain a dil. acid and then the acid such as HOAc (which may be recovered at about 170–220°) Brit. 302,269 describes the concn. of similar acids from their solns. in org. solvents by treating the latter with salts such as NaOAc as described in Brit. 291,434 (C. A. 23, 1141) and then distg. the acid from the acid salt in the form of a paste or soln. without previous sepn. of the salt in solid form. The distn. may be under reduced pressure at 170–220°.

**Acetic acid.** HERMANN SUDA. Fr. 33,971, Aug. 5, 1927. Addn. to 593,091. Concd. AcOH is obtained from dil. AcOH by extn. of a superheated mixt. of steam and acid by a solvent having a b. p. appreciably higher than that of the AcOH, and only slightly or not sol. in water, such as acyl or acetyl derivs. of aliphatic polyalcs. or of higher alcs. or acyl or acetyl derivs. of the tars or creosotes used in the prior case. Cf. C. A. 23, 2449.

**Acetic acid from acetaldehyde.** HOWARD W. MATHESON (to Canadian Electro Products Co., Ltd.). U. S. reissue 17,377, July 16. See original pat. No. 1,410,207 (C. A. 16, 1781).

**Butyric acid.** LEFRANC & CIE. Ger. 478,116, July 29, 1922. See Brit. 186,572 (C. A. 17, 324).

**Anthraquinonedisulfonic acid.** DONALD G. ROGERS and HAROLD T. STOWELL (to National Aniline & Chemical Co.). U. S. 1,721,317, July 16. In the production of 1,5- and 1,8-disulfonic acids from anthraquinone, sulfonation is effected in the presence of Hg at a temp. of about 140–60° with oleum contg. about 24–26% free SO<sub>3</sub> which is used in sufficient quantity to sulfonate all of the anthraquinone with the free SO<sub>3</sub> present, and heating of the mixt. is continued until the sulfonation mass is substantially completely sol. in water.

**Naphthenic acid.** STEWART P. COLEMAN (to Standard Oil Development Co.) U. S. 1,720,821, July 16. In treating material such as petroleum oils or fractions, high-boiling org. acids are sepd. from the bulk of assoc. oil by converting the acids to salts with alkali, dissolving the salts in water and sepg. aq. and oily layers. The acids are liberated from their salts by treating the aq. soln. with inorg. acid and the liberated acids are withdrawn, the acids are reconverted to salts with alkali and the material is distd. *in vacuo* to remove all traces of oil and the unvaporized salts are withdrawn and acids are recovered from them. An arrangement of app. is described.

**3'-Nitro-4'-acylamino-*o*-benzoylbenzoic acid.** ROGER ADAMS and WENDELL W. MOYER (to Newport Co.). U. S. 1,720,751, July 16. 3'-Nitro-4'-chloro-*o*-benzoylbenzoic acid is condensed with an acyl substituted ammonia such as *p*-toluenesulfonamide in the presence of a Cu catalyst. From the nitro compds. thus obtained, the corresponding 3'-amino-4'-acylamino-*o*-benzoylbenzoic acids may be obtained by treating the nitro compd. in alc. with powdered Fe and dil. acid, making alk., filtering off the iron sludge and neutralizing the filtrate with acid to ppt. the product. U. S. 1,720,752 relates to the production of amino derivs. by this method.

**Aliphatic anhydrides.** HENRY DREYFUS. Fr. 656,901, July 2, 1928. Ac<sub>2</sub>O and other anhydrides are produced by heating the vapors of the acids which may be dil.,

the anhydrides being condensed and the water carried away by vapor of  $\text{CCl}_4$ , petrol,  $\text{C}_6\text{H}_6$ , or mixts. of these or of ether with petroleum ether, etc., which do not dissolve the anhydride and boil below  $100^\circ$ . An app. is described. Fr. 656,902 describes the production of the same anhydrides, the water being sepd. from the anhydrides by passing the vapors under the surface of a cooled extn. liquid such as  $\text{C}_6\text{H}_6$ ,  $\text{CHCl}_3$ , mixts. of ether or  $\text{CHCl}_3$  with one or more light hydrocarbons (petroleum ether), gasoline,  $\text{C}_4\text{H}_{10}$ , or its homologs, which dissolve the anhydride. An app. is described. Cf. C. A. 23, 2447.

**Aliphatic anhydrides.** HENRY DREYFUS. Fr. 657,423, July 11, 1928.  $\text{Ac}_2\text{O}$  and other aliphatic anhydrides are produced by mixing the acid as spray or vapor with an inert gas such as steam, superheated steam, N or H heated to  $600$ – $1200^\circ$ , the acid being preferably preheated to  $150$ – $300^\circ$ . The anhydride may be sepd. by fractional condensation, passing through a solvent such as chlorobenzenes, benzyl ether, tetrachloroethane, acetins, anisole, *p*-cresyl acetate, phenetole, paraffin oil or mixts. thereof, or by means of an entraining liquid or water-binding substance. An app. is described.

**Acetic anhydride.** I. G. FARBENIND. A.-G. Brit. 301,562, Sept. 6, 1927. Water vapor is sepd. by diffusion (as through a heated graphite tube within a quartz tube) from a mixt. contg.  $\text{Ac}_2\text{O}$  such as may be produced by heating  $\text{HOAc}$ , and after repeated diffusion sepn. the  $\text{Ac}_2\text{O}$  and assocd.  $\text{HOAc}$  are sepd. by distn. Cf. C. A. 23, 3932.

**Phthalic anhydride.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Ger. 478,192, Dec. 13, 1924. In the manuf. of phthalic anhydride from  $\text{C}_{10}\text{H}_8$  by oxidation with air in the presence of a catalyst such as  $\text{V}_2\text{O}_5$ , improved results are obtained by supporting the catalyst on a smooth or polished metal carrier. Thus, a contact mass may be prepd. by immersing small pieces cut from a polished sheet of Al into molten  $\text{V}_2\text{O}_5$ .

**Acetaldehyde.** H. S. HIRST and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 302,515, Jan. 25, 1928. Gases contg. relatively small proportions of  $\text{C}_2\text{H}_2$  are used as sources of  $\text{C}_2\text{H}_2$  for acetaldehyde production by washing in counter-current with a catalytic medium such as a liquor contg.  $\text{H}_2\text{SO}_4$  10–20,  $\text{HgSO}_4$  1 and  $\text{Fe}_2(\text{SO}_4)_3$  7%. Various details and auxiliary features of procedure are described.

**Acetaldehyde.** I. G. FARBENIND. A.-G. Fr. 657,027, July 5, 1928.  $\text{AcH}$  is prepd. from  $\text{C}_2\text{H}_2$  or gaseous mixts. contg.  $\text{C}_2\text{H}_2$  by treating the gases with a soln. of an alkali bisulfate contg. Hg compds. and other heavy metal compds. An example is given in which a gaseous mixt. obtained by treating  $\text{CH}_4$  in an elec. arc, or pure  $\text{C}_2\text{H}_2$  is passed through a soln. of  $\text{KHSO}_4$  contg. Hg oxide and 0.5%  $\text{CuSO}_4$  at  $70^\circ$ .

**Ether.** NEDERLANDSCHE GIST- EN SPIRITUSFABRIEK. Ger. 478,388, July 19, 1924. Corresponds to Brit. 219,272 (C. A. 19, 524), but gives addnl. exptl. details.

**Ethyl chloride.** I. G. FARBENIND. A.-G. (Hermann Suida, inventor). Ger. 478,082, June 13, 1924. The manuf. of  $\text{EtCl}$  by the combination of  $\text{C}_2\text{H}_4$  and  $\text{HCl}$  under pressure in the presence of a catalyst is conducted at a temp. below  $100^\circ$  in a liquid medium which dissolves the reagents under the prevailing conditions without undergoing chem. change.  $\text{EtCl}$  itself is the preferred solvent.

**Trichloroethylene.** CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 302,321, Dec. 14, 1927. Acetylene tetrachloride vapor is passed at high speed and a temp. of about  $500^\circ$  over large surfaces in a reaction chamber to effect partial conversion into trichloroethylene. Among the contact materials which may be used are: pumice, wood charcoal, active C and silica gel. Metal oxides and salts also may be used as catalysts.

**Ethylene glycol.** ALBERT MAIER. Fr. 656,651, June 29, 1928.  $\text{C}_2\text{H}_4(\text{OH})_2$  is prepd. from  $\text{C}_2\text{H}_4\text{Cl}_2$  by sapon. with water at temps. above  $120^\circ$ , under pressure. Any  $\text{HCl}$  formed is neutralized by the continuous addn. of an alkali or appropriate metallic oxide. Most of the water is distd. off and the glycol is extd. from the mud by means of alc.

**Catalyst for the preparation of ethylidene diacetate.** HOWARD W. MATHESON and FREDERICK W. SKIRROW (to Canadian Electro Products Co.). U. S. 1,720,184, July 9. A Hg oxide is dissolved in  $\text{HOAc}$  and fuming  $\text{H}_2\text{SO}_4$  is added to combine with the water in the resulting aq. Hg acetate soln. and ppt. the Hg as a finely divided and reactive sulfate which is suitable for use as a catalyst in making ethylene diacetate from  $\text{C}_2\text{H}_4$ .

**Chlorohydrins.** TH. GOLDSCHMIDT A.-G. Fr. 656,947, July 3, 1928. See Brit. 293,754 (C. A. 23, 1651).

**Formamide.** I. G. FARBENIND. A.-G. Brit. 301,974, Sept. 17, 1927. See Fr. 646,815 (C. A. 23, 2191).

**Synthetic ephedrine (phenylmethylaminopropanol).** E. FOURNEAU (to Soc. des usines chimiques Rhône-Poulenc). Brit. 302,940, Dec. 23, 1927.  $\alpha$ -Methylamino-

ethyl phenyl ketone is hydrogenated (suitably in the form of its hydrochloride dissolved in alc.) with use of finely divided Pt as catalyst. The starting material is produced by the reaction of bromopropiophenone with methylamine in  $C_6H_6$  or alc. soln. Bromopropiophenone is prepd. either by direct bromination of propiophenone or by treating  $C_6H_6$  with bromopropionyl bromide in the presence of  $AlCl_3$ .

**4-( $\beta$ -Hydroxyethylamino)phenol.** I. G. FARRENIND. A.-G. Brit. 301,808, Dec 5, 1927. Hydroquinone is heated with 2-aminoethanol, without necessity of employing a condensing agent. Several examples with details are given. Cf. C. A. 23, 1420.

**Civetone.** LEOPOLD RUZICKA (to M. Naef & Co.). U. S. 1,720,748, July 16. The quantity of civetone obtainable from neutral civet oil is increased by oxidizing the civetol in the oil to civetone. Several modes of treatment are described. Cf. C. A. 22, 1163.

**Thymol.** RHEINISCHE KAMPFER-FABRIK G. M. B. H. Fr. 657,416, July 3, 1928. See Brit. 293,753 (C. A. 23, 1651).

## 11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

**Comparative studies on the breakdown of polypeptides, their derivatives, and amides by normal alkali, erepsin and trypsin or trypsin-kinase.** EMIL ABDERHALDEN AND WALTER ZEISSET. *Fermentforschung* 10, 544-85(1929).—New polypeptides were prepd. in the usual manner by coupling a di- or tripeptide with a halogenacyl halide and aminating with  $NH_4OH$ . *dl- $\alpha$ -Bromoisovaleryl-glycyl-glycine*, m. 117°,  $\rightarrow$  *dl-valyl-glycyl-glycine*, m. 241-2° (decompn.); *dl- $\alpha$ -bromoisovaleryldiglycyl-glycine*, m. 171-3° (decompn.),  $\rightarrow$  *dl-valyldiglycyl-glycine*, decompn. 230-5° without melting; *dl- $\alpha$ -bromoisocapronylglycyl-dl-valine*, m. 143-5°,  $\rightarrow$  *dl-leucylglycyl-dl-valine*, m. 244-5° (decompn.); *dl- $\alpha$ -bromoisovaleryl-glycyl-dl-leucine*, m. 169°, *dl-valylglycyl-dl-leucine*, m. 242-4° (decompn.); *dl- $\alpha$ -bromoisovaleryl-glycyl-dl-valine*, m. 179-80°,  $\rightarrow$  *dl-valyl-glycyl-dl-valine*, m. 233-5° (decompn.); *chloroacetyl-glycyl-dl-valine*, m. 170°,  $\rightarrow$  *glycyl-glycyl-dl-valine*, m. 219-21° (decompn.); *chloroacetyldiglycyl-dl-valine*, m. 169-71° (decompn.),  $\rightarrow$  *glycyldiglycyl-dl-valine*, m. 147-9°; *chloroacetyl-glycyl-dl-leucine*, m. 153°,  $\rightarrow$  *glycylglycyl-dl-leucine*, m. 240° (decompn.); *chloroacetyldiglycyl-dl-leucine*, m. 176-7° (decompn.),  $\rightarrow$  *glycyldiglycyl-dl-leucine*, m. 206-8° (decompn.); *bromoacetyl-dl-leucylamide*, m. 173-4°,  $\rightarrow$  *glycyl-dl-leucylamide* -IIBr, m. 175-9°; *dl- $\alpha$ -bromoisocapronyl-dl-leucylamide*, m. 141-3°,  $\rightarrow$  *dl-leucyl-dl-leucylamide* -IIBr, m. p. not stated. *dl*-Valylglycyl-glycine had previously been prepd. and found to be resistant to *N* alkali at 37°. This later prepn. under the same conditions underwent hydrolysis. The difference in behavior is left unexplained. The intermediate bromoisovalerylglycyl-glycine in the 2 preps. showed different cryst. forms, but otherwise appeared to be identical. As already noted with other peptides, a multiplicity of glycyl groupings renders these peptides more susceptible to cleavage by alkali. It makes apparently no difference at which end of the peptide chain a glycine grouping is placed. The 3 peptide amides undergo hydrolysis with a splitting off of the amide group. The halogenacyl derivs. are strongly hydrolyzed by alkali, the chloroacetyl even more readily than the corresponding bromoisovaleryl derivs. Not only is the peptide linkage broken, but halogen is also split off. Differences were noted in the cleavage of peptides by different preps. of erepsin. *dl*-Valylglycyl-glycine was not attacked by an erepsin prepn. which was active toward the other peptides, but it was readily hydrolyzed by other erepsin preps. Erepsin hydrolyzed *dl*-leucylamide, but not glycylamide; *dl*-leucylglycylamide readily, glycyl-dl-leucylamide slightly and *dl*-leucyl-dl-leucylamide not at all. Erepsin-free trypsin did not attack any of the amides. It was without action on glycine chains from the di- to the hexapeptide. Of the polypeptides contg. *dl*-valine or *dl*-leucine in addn. to glycine, only those were hydrolyzed which carried more than 1 valyl or leucyl group. An exception was the tetrapeptide glycyldiglycyl-dl-leucine which, however, showed only 12% cleavage in 24 hrs. This observation is in harmony with previous experience that a terminal leucine aids tryptic hydrolysis. A. W. D.

**The problem of specific relations of erepsin and trypsin to definite atomic groupings in polypeptides.** EMIL ABDERHALDEN AND OSKAR HERRMANN. *Fermentforschung* 10, 586-90(1929).—One method of detg. the point of attack on polypeptides by sp.

enzymes consists in observing the change in rotation of optically active tripeptides. The sp. rotation of the tripeptide, and of its 3 amino acid and 2 dipeptide components, must all be known. There must also be sufficient difference in rotation between the 2 possible mixts. of cleavage products to make their identification possible. *d-Alanyl-glycyl-l-phenylalanine*, m. 220°,  $[\alpha]_D^{20}$  34.02°, showed a decrease in *d*-rotation after ereptic digestion and a change to *l*-rotation after tryptic digestion. In this case *l*-phenylalanine is the only possible product with *l*-rotation, and the change in sign of rotation after tryptic digestion indicates the liberation of this amino acid. A cleavage into *d*-alanine and glycyl-*l*-phenylalanine, on the other hand, should increase the *d*-rotation. But in both digestions it appears that the dipeptide formed undergoes further hydrolysis. This tripeptide was prepd. from the dipeptide by the usual procedure via *d*- $\alpha$ -bromopropionylglycyl-*l*-phenylalanine, m. 150°. It is not well adapted to the purpose in view. The tripeptide, *l*-leucylglycyl-*d*-alanine, is more suitable for distinguishing between ereptic and tryptic hydrolysis. A splitting off of *d*-alanine should increase the *d*-rotation, whereas a splitting off of *l*-leucine should invert it. These opposite effects were obtained with trypsin and erepsin, resp. Yeast maceration, kidney press juice and liver press juice all behaved like erepsin. The observations confirm the view previously expressed that erepsin splits off the amino acid contg. the free NH<sub>2</sub> and trypsin that contg. the free COOH.

A. W. Dox

Further comparative studies on the breakdown of polypeptides and their derivatives at various hydrogen-ion concentrations and by erepsin and trypsin-kinase. Studies on the optimal hydrogen-ion concentration for the action of these enzyme complexes. EMIL ABDERHALDEN AND ADOLF SCHMITZ. *Fermentforschung* 10, 591-609(1929).—A no. of polypeptides and their PhNCO and halogenacyl derivs. were tested with respect to the influence of varying  $p_H$  values, with and without enzyme, on the rate of cleavage. Hydrolysis by alkali occurs more readily with the halogenacyl derivs., and still more readily with the PhNCO derivs. than with the free peptides at the same  $p_H$ . The length of the peptide chain is also of considerable influence. Different peptides show different optimum  $p_H$  values for cleavage. Trypsin-kinase gives a max. cleavage of *dl*-leucylglycyl-*dl*-leucine at  $p_H$  7.8, of *dl*-leucylglycyl-*l*-tyrosine at both 9.0 and 7.8 and of glycyl-*dl*-leucylglycyl-*dl*-leucine at 9.0. Halogenacyl derivs., on the other hand, undergo cleavage most readily near the neutral point, but even here differences are noted between different substrates. The problem is complicated by a no. of factors: (1) the intermediate products of hydrolysis represent new substrates with different  $p_H$  optima for cleavage; (2) it is probable that neither the erepsin nor the trypsin complex is an individual enzyme; (3) different substrates are probably dissoed. to different extents at different  $p_H$  values; and (4) the possibility must be reckoned with that the optimum  $p_H$  for dissoen. and that for formation of enzyme-substrate complex are not the same. New preps. described are: *dl*-leucylglycyl-*l*-tyrosine PhNCO deriv., decomp. 130°, and glycyl-*dl*-leucylglycyl-*dl*-leucine PhNCO deriv., decomp. 144-5°.

A. W. Dox

Further studies on the influence of various additions— $\alpha$ - and  $\beta$ -amino acids, hippuric acid, sarcosine, aniline, dipeptides—on the rate of cleavage of polypeptides by the erepsin and the trypsin-kinase complex. EMIL ABDERHALDEN AND OSKAR HERRMANN. *Fermentforschung* 10, 610-6(1929).—The effect of addn. of various substances, mainly amino acids, on the enzymic hydrolysis of *dl*-valylglycine, *dl*- $\alpha$ -aminobutyrylglycine, *dl*-leucylglycyl-*dl*-leucine and the ClCH<sub>2</sub>CO derivs. of *l*-tyrosine and *l*-phenylalanine was studied. No direct relationship could be established between the nature of the added substance and the enzyme complex employed. The promoting or inhibiting action varied as much with different substrates as with different enzymes.

A. W. Dox

Anserine, a new constituent of avian musculature. D. ACKERMANN, O. TIMPE and K. POLLER. *Z. physiol. Chem.* 183, 1-10(1929).—The discovery of  $\gamma$ -butyrobetaine in reptilian muscle by Keil, Linneweh and Poller (*C. A.* 22, 1601) suggested the possible occurrence of an unknown base in avian muscle. The flesh from a large no. of geese was extd. with H<sub>2</sub>O and the ext. examd. by the Kutscher method for the sepn. of bases. The so-called lysine fraction contained a new base precipitable by alc. picric acid and by alc. HgCl<sub>2</sub> and capable of isolation as the chloroaurate. The base, for which the name *anserine* is proposed, has the formula C<sub>10</sub>H<sub>16</sub>N<sub>4</sub>O<sub>3</sub>. It was found also in the Ag-Ba ppt. A still better precipitant is flavianic acid, which may be added directly to the concd. ext. without preliminary purification by tannin or Pb(OAc)<sub>2</sub>. Finally, the Dietrich method for isolation of carnosine was found to be the most satisfactory for isolating this substance. It consists in pptg. the concd. ext. by 10% HgSO<sub>4</sub> in 10% H<sub>2</sub>SO<sub>4</sub> and adding EtOH, or better, MeOH. The ppt. is washed with MeOH and

boiled with  $\text{H}_2\text{O}$ . It is then decompd. by  $\text{H}_2\text{S}$ , the  $\text{H}_2\text{S}$  removed from the filtrate by aeration, and the soln. nearly neutralized by  $\text{Ba}(\text{OH})_2$ . Addn. of  $\text{HgSO}_4$  in  $\text{H}_2\text{SO}_4$  without  $\text{MeOH}$  then removes impurities, and addn. of  $\text{MeOH}$  with more  $\text{HgSO}_4$  to the filtrate reprecipitates the base, the liberation of which is performed as before. Boiling with  $\text{CuCO}_3$ , and octyl alc. to prevent foaming, and concn. of the filtrate yields crystals of *anserine Cu*. The latter occurs in 2 modifications, an ultramarine blue and a reddish lilac. Each is convertible into the other and neither contains  $\text{H}_2\text{O}$  of crystn. The red modification is less sol. than the blue. Both decomp.  $230-2^\circ$  with foaming. The *free base*, m.  $238-9^\circ$ ,  $[\alpha]_D^{18}$   $11.26^\circ$ , is obtained by dissolving the  $\text{Cu}$  deriv. in warm dil.  $\text{H}_2\text{SO}_4$ , removing the  $\text{Cu}$  by  $\text{H}_2\text{S}$  and the  $\text{H}_2\text{SO}_4$  by  $\text{Ba}(\text{OH})_2$ . The *nitrate*, m.  $216-8^\circ$  (foaming), is pptd. cryst. by  $\text{MeOH}$ ; *chloroplatinate*, decomp.  $215-20^\circ$ ; *chloroaurate*, m.  $90-5^\circ$ ; *monopicrate*, decomp.  $205-8^\circ$ ; the last 3 sep. as oils which soon become cryst. Anserine is pptd. by phosphotungstic acid, alc.  $\text{HgCl}_2$ , aq.  $\text{Hg}(\text{NO}_3)_2$ , Hopkins' reagent with  $\text{MeOH}$  or  $\text{EtOH}$ , incompletely by aq.  $\text{HgCl}_2$ , and gives a cloudiness with picrolonic acid, ammoniacal  $\text{Ag}$ , and an oily sepn. with alc. picric acid and Dragendorff's reagent. An impurity rather difficult to remove gives the Pauly diazo reaction. Millon, Hopkins' glyoxylic acid, Sakaguchi, Knoop's Br, biuret and murexide tests are neg. The ninhydrin reaction is pos. From 5.7 kg. of fresh goose meat 8.4 g. anserine  $\text{Cu}$  was obtained, corresponding to a 0.12% yield of free base. A. W. DOX

**Fractionation of the water-soluble proteins of blood serum.** STEFAN GOLDSCHMIDT and HERBERT KAHN. *Z. physiol. Chem.* 183, 19-31(1929).—The albumin fraction, obtained by satn. of the blood serum with  $(\text{NH}_4)_2\text{SO}_4$  after removal of the globulin fraction by 0.5 satn., is of diagnostic significance since its amt. is greatly diminished when any considerable tumorous growth is present. It was desired to ascertain whether this albumin fraction represents an individual substance or a mixt. By fractional pptns. of bovine serum with  $(\text{NH}_4)_2\text{SO}_4$  in increasing concns. 3 sep. fractions were obtained. These were examd. to det. whether they differed merely in phys. characteristics such as size of the particles, or whether chem. differences could be demonstrated. Elementary analyses of the 3 successive fractions showed a progressive increase in S, the values being 1.78, 1.85 and 2.20%, resp. N distribution, as detd. by the Van Slyke method, showed a no. of differences, the most striking of which were the histidine values, 0.25, 0.52 and 6.60%, resp. Tryptophan decreased from 1.1 to 1.05 to 0. A biol. difference was the absence of anaphylaxis following injection of fraction III into other animal species. Thus the so-called serum albumin is not an individual substance. The most sol. fraction (fraction III) comprises 4% of the total albumin. Its high histidine content suggests a biol. relationship to globin. A. W. DOX

**Blood coagulation. Inhibition and acceleration.** ERNST WALDSCHMIDT-LEITZ, PAUL STADLER and FELIX STRIGERWALDT. *Z. physiol. Chem.* 183, 39-59(1929)—See C. A. 23, 1424. A. W. DOX

**Chemistry of the blood pigment. X. Specificity of the hemoglobins and the v. Krüger reaction.** FELIX HAUROWITZ. *Z. physiol. Chem.* 183, 78-87(1929); cf. C. A. 23, 3238.—As far back as 1888 v. Krüger detd. the rates at which the blood pigment of different animals is decompd. by alkali. His method consisted in measuring the time interval between the addn. of 0.2 vol. 0.25 N  $\text{NaOH}$  and the disappearance of the 2 absorption bands of oxyhemoglobin. The time varied between 40 and 50 sec. for human and 24 hrs. for bovine hemoglobin. It is now shown that differences in velocity of denaturation of the globin component are the cause of the variations in resistance of hemoglobin to  $\text{NaOH}$ . Denatured globin can be pptd. by  $1/3$  satn. with  $(\text{NH}_4)_2\text{SO}_4$  in the presence of  $\text{NH}_4\text{OH}$ , leaving native globin in soln. This sepn. was made at different periods in the alkali decompn.; the protein in each fraction was pptd. by tungstic acid and the N detd. by the Kjeldahl method. The content of unaltered hemoglobin was also detd. colorimetrically and found to be in close agreement with the value obtained by the salting out method. Furthermore, the rate of transformation of oxyhemoglobin into catemoglobin was detd. by spectroscopic observations and calens from the extinction coeffs. The rate of decompn. of hemoglobin from different animals was the same as that reported by v. Krüger, viz., man, dog, rabbit, horse, guinea pig and steer, in decreasing order. A. W. DOX

**The purine bases in the urine of the dog.** H. LETHAUS. *Z. physiol. Chem.* 183, 98-102(1929).—By working up a large quantity (100 l.) of urine collected from 3 dogs the following purines were isolated and identified: uric acid, adenine, xanthine and probably hypoxanthine. The excretion of these purines by the dog, an animal with more than the usual capacity for destroying uric acid, is considered significant. A. W. DOX

**Reduced hematin and hemochromogen.** R. HILL. *Proc. Roy. Soc. (London)* B105, 112-30(1929).—Reduced hematin has a soly. ranging between  $10^{-4}$  and  $10^{-5}$  M, according to the salts present in the soln. Pyridine, nicotine and alkali cyanide (2 mol.) and reduced hematin (1 mol.) are present in pyridine-, nicotine- and cyano-hemochromogen, resp. These hemochromogens behave as simple compds. of the type  $HtnA_2$ , in which Htn represents reduced hematin and  $A_2$  the 2 mol. of nitrogenous compd.; however, they readily aggregate in concd. soln. At a temp. of  $16^\circ$ , the dissocn. consts. of these hemochromogens were: pyridine-  $8.9 \times 10^{-6}$ , nicotine-  $1.1 \times 10^{-7}$ , cyano-  $4.8 \times 10^{-8}$ . A hemochromogen was also obtained contg. 1 mol. nicotine, 1 mol. cyanide and 1 mol. reduced hematin; its dissociation const. was approx.  $0.38 \times 10^{-8}$ . The so-called hemochromogen, which contains 1 mol. KCN and 1 mol. reduced hematin, is analogous to CO-reduced-hematin, and should be designated cyano-reduced hematin; its dissocn. const. is approx.  $1.3 \times 10^{-8}$ . Hemochromogen and reduced hematin can be detd. by means of the spectroscope. JOSEPH S. HEPBURN

**The purification of pepsin.** J. C. FORBES. *J. Chem. Education* 6, 1277-81(1929).—A review. E. H.

**Recent researches on the biochemistry of the nitrogen cycle.** GILBERT J. FOWLER. *Chemistry & Industry* 48, 673-8(1929); cf. *C. A.* 23, 2729. E. H.

**The solubility of urinary uric acid.** RUGGERO ASCOLI. *Biochim. terap. sper.* 16, 205-13(1929); cf. *C. A.* 23, 163, 168, 3482.—A general review. PETER MASUCCI

**The influence of ultra-violet radiations on the blood sugar of the rabbit.** F. G. HALL AND R. W. ROOT. *J. Elisha Mitchell Sci. Soc.* 43, 187-92(1928).—Rabbits irradiated with Hg quartz lights show a decided increase in blood sugar concn. Radiations from the same lamp after being filtered through glass raise the blood sugar concn. less than unfiltered rays. Development of a resistance to the effects of light is indicated by a lessened response after several exposures. A. L. MEHRING

**The specificity of animal proteases. XVI. Dipeptidase and polypeptidase from intestinal mucous membrane.** ERNST WALDSCHMIDT-LEITZ, ARNOLD K. BALLS AND JOHANNA WALDSCHMIDT-GRASER. *Ber.* 62B, 956-62(1929); cf. *C. A.* 22, 2381, 3173; 23, 3244.—Erepsin is a mixt. of a dipeptidase and a polypeptidase. The affinity of both for  $Al_2O_3$  is nearly the same. This permits their sepn. from pancreatic trypsin. They are sepd. from each other by adsorption with  $Fe(OH)_3$ . Eighty cc. glycerol ext. is purified with AcOH and 3 cc. acetate buffer of  $p_H$  3.8 and 10 cc. of a suspension of  $Fe(OH)_3$  contg. 327.6 mg. are added. The polypeptide remains in the soln. The dipeptide is washed out with alk. liquid. The optimum for the dipeptide is  $p_H$  8, for the polypeptide  $p_H$  7.0. The effect of the dipeptide was detd. by observing the action on *dl*-leucylglycine, that of the polypeptide on *dl*-leucyldiglycine, by using 0.001 mol. peptide at  $p_H$  7.0 and  $30^\circ$  in a vol. of 10 cc. The polypeptidase unit used is 1000 times the amount of enzyme giving the const. 0.001 for the monomol. reaction. A. E. MEYER

**The molecular weight of proteins; the molecular weight of hemocyanin from the blood of the snail (*Helix pomatia*).** CH. BAUMELER. *Rev. gén. colloïdes* 7, 145-52 (1929).—A review of the work of Svedberg is given by which he has detd. the mol. wts. of a no. of proteins by supercentrifugal methods. A comparison is given of these results with those furnished by other methods, especially the method of ultrafiltration. The hemocyanin of the snail has a much higher mol. wt. than that of other proteins; nevertheless hemocyanin crystallizes readily. L. B. MILLER

**Glucose fixation by the red blood cells.** F. HÖGLER, A. THOMANN AND K. ÜBER-  
RACK. *Biochem. Z.* 209, 1-31(1929).—The factor of swelling plays an important role in the study of glucose fixation by erythrocytes by Loewi's method, since it affects the absorption of glucose. But even when this swelling factor is taken into consideration certain discrepancies appear in both insulin and dialysis expts. that cannot be explained. A careful recalcn. of the method reveals that the degree of accuracy of the Loewi method is not sufficient to allow any definite conclusion from the small variations observed. Human red blood corpuscles freed of their sugar by repeated washing take up glucose from a glucose soln. by a process of diffusion. It is indicated that in the expts. by Loewi's method the taking up of sugar by the cells is likewise principally a diffusion process. S. MORGULIS

**Inhibition of the hematin catalysis by hydrogen sulfide.** HANS A. KREBS. *Biochem. Z.* 209, 32-3(1929); cf. *C. A.* 23, 1917.—Hemin acts as an oxidation catalyzer and this catalysis is affected by CO or HCN just as is cell respiration. The inhibition of catalysis by  $H_2S$  can be also demonstrated when linoleic acid instead of cysteine is used as substrate. This is made up by dissolving 0.2 g. linoleic acid in 20 cc. of pyridine borate of  $p_H$  10.3 (3 M pyridine and 0.5 M borate buffer). The oxidation of this

by 0.01 mg. hemin per cc. soln. is completely inhibited by  $4 \times 10^{-4}$  M  $H_2S$ .

S. MORGULIS

**The sulfur content of melanotic pigments.** F. SCHAAF. *Biochem. Z.* 209, 79-82 (1929).—Typical, S-rich melanins prepd. according to the methods described in the literature from horse hair as well as from liver metastases of a primary melanocarcinoma of the skin could be very largely freed of their S content without in any way affecting the other pigment properties. The melanin could not be freed from the traces of Fe as well as of S, and the latter is probably of as little importance as a pigment ingredient as the former is known to be.

S. MORGULIS

**Diffusion experiments on sugar protein solution.** D. KRÜGER. *Biochem. Z.* 200, 119-27 (1929).—Diffusion expts. were made with glucose-protein as well as glucose-amino acid solns. over which was placed solns. free from either protein or amino acid and the results show that the diffusion of the glucose proceeds as if no protein or amino acids were present. Conclusion: No appreciable condensation of glucose and protein takes place.

S. MORGULIS

**The absorption of dyestuffs and of their leuco compounds as a preliminary to the photobiological sensibilization in the ultra-violet.** W. HAUSMANN AND O. KRUMPELL. *Biochem. Z.* 209, 142-7 (1929).—The absorption in the ultra-violet is compared for a 2-nuclei pyrrole dye and its leuco compd. The absorption of the latter indicates the possibility of photobiological sensibilization in that spectral region. Likewise the absorption in ultra-violet of meso-porphyrinogen indicates that photobiological sensibilization can be achieved with this precursor of porphyrin.

S. MORGULIS

**Inactivation of enzymes by tannins.** A. OPARIN AND A. KURSANOV. *Biochem. Z.* 209, 181-94 (1929).—Enzyme detn. on tannin-contg. leaves is very difficult, since the tannins go into soln., mix with the enzymes and inactivate them. However, the addn. of egg albumin or peptone to such enzyme exts. restores completely their action. The regenerated enzymes can now be detd. The inactivation is due to the adsorption of the enzymes by the pptd. protein, while the regeneration is due to the elution of the adsorbed enzymes by the egg albumin or the peptone solns.

S. MORGULIS

**Studies of tyrosinase. I. The oxidation and reduction potentials of the tyrosinase system.** DAISABURO OKUYAMA. *J. Biochem. (Japan)* 10, 463-79 (1929).—Tyrosinase gives a high reduction potential with *p*-cresol and glycine in N gas. Tyrosine itself shows a sufficiently high reduction potential which is not increased by tyrosinase even in the presence of glycine. The reduction potential of catechol or hydroquinone, but not that of resorcinol, is increased by tyrosinase in the presence of glycine.

S. MORGULIS

**Investigations of carbohydrates by bacteriological methods.** B. KLEIN. *Centr. Bakt. Parasitenk.*, I Abt., 112, 447-50 (1929).—A rapid method for the study of carbohydrate fermentation in Barsiekow medium is suggested. One cc. of medium is inoculated with 2 loops (agar culture) of bacteria. Acid formation can be read in 1 to 4 hrs. ordinarily. *B. coli communis* ferments dextrose in 0.5 hr., levulose, galactose and mannose in 1 hr., arabinose in 2 hrs., xylose in 3-4 hrs., rhamnose in 4-5 hrs., maltose in 1.5-3 hrs., polyatomic alcs. as mannitol in 1-1.5 hrs., glycerol and dulcitol in 20 hrs. There is a definite relationship between the chem. formula of the carbohydrate and the time required for fermentation. Steriosomerism plays a part.

J. T. M.

**The prearginine in edestin and its resistance to hydrolysis.** HENRY S. SIMMS. Rockefeller Inst. *J. Gen. Physiol.* 12, 231-9 (1928).—The name "prearginine" is given to that portion of the protein mol. having a basic group which ionizes at about *pH* 4.6 and yields arginine on hydrolysis. It may be composed of one or more amino acids. Expts. show that all the arginine found on the hydrolysis of edestin is "prearginine." The extra ionizable groups of histidine, lysine and tyrosine in edestin are free in the quantities found on hydrolysis. Part of the extra carboxyl groups of aspartic and glutamic acids are bound as amides; 50% are bound in some other manner, possibly as anhydrides, and about 6% of these groups are free to ionize. The prearginine is not converted into arginine on hydrolysis with pepsin up to 18% of the total hydrolysis. On still further hydrolysis the conversion is masked by the high buffer effect of the soln. Complete hydrolysis converts prearginine into arginine which can be isolated. Hydrolyzed edestin promotes the growth of sarcomatous fibroblasts whether hydrolysis is 5, 14 or 18% completed.

C. H. RICHARDSON

**Chemical antagonism of ions. I. Effect of Na-Mg and K-Mg mixtures on the activity of oxalic diion.** HENRY S. SIMMS. *J. Gen. Physiol.* 12, 241-58 (1928).—Mg ions decrease the activity of bivalent org. anions much more than do Na ions, the effect being especially large with short chain acids like oxalic. The addn. of Na or K ions produces a marked decrease in the effect of Mg ions on the activity of oxalate ions. An

equation is given which is obeyed by 0.005 *M* solns. of oxalic diion over wide ranges of concns. of  $MgCl_2$ , and of  $NaCl$  or  $KCl$ . The equation is valid in the physiol. range. This constitutes a definite chem. antagonism in pure, non-colloidal soln. It is hoped the results will throw some light on physiol. and colloidal antagonisms. **II. Antagonism between anions and also between cations and anions in their effect on oxalate activity.** *Ibid* 259-67.— $SO_4$  ions produce an anomalous effect on the ionization of oxalate diion, opposite in direction to the effect of  $Mg$  ions. This effect of sulfate is antagonized by the presence of  $Cl$  ions according to the equation:  $k = (f' - 1) \times (2SO_4^{--} + Cl^- + A)/(SO_4^{--})^{1.5}$ , where  $f'$  is the antilog of the increase in  $pK'$ , due to the sulfate. In solns. containing up to 0.03 *M*  $MgSO_4$  the effect of  $Mg^{++}$  predominates over that of  $SO_4^{--}$ . Above 0.1 *M* the effect of  $SO_4^{--}$  predominates and tends to neutralize the initial deviation. In solns. containing fixed amts. of  $MgCl_2$  and varying amts. of  $Na_2SO_4$  (or *vice versa*) the effects of these two salts sharply antagonize each other in all proportions. C. H. RICHARDSON

**The effect of valence of ions on cellular permeability to water.** BALDWIN LUCKÉ AND MORTON McCUTCHEON. *J. Gen. Physiol.* 12, 571-80(1929).—Permeability of unfertilized eggs of the sea urchin, *Arbacia punctulata*, to water, as measured by rate of swelling in hypotonic glucose soln. is greatly affected by the addn. of low concns. of electrolytes. Permeability to water decreases with increase in valence of the cation of the electrolyte. Cobaltamine chlorides with valence of 1 to 6 were used in these expts. Increase in permeability to water occurred when the valence of the anion increases as shown by a series of K salts. The effect of electrolytes on permeability to water depends chiefly on the sign and no. of elec. charges on the ion, positive ions decreasing, negative ions increasing permeability of the eggs to water. The effectiveness of the ion is greater the higher its valence. The method employed may be used to study *ion antagonism*. Antagonism was demonstrated between cations and anions. C. H. RICHARDSON

**Pyridine hemochromogen.** A. E. MIRSKY AND M. L. ANSON. *J. Gen. Physiol.* 12, 581-6(1929).—Cyanide hemochromogen probably contains 1 CN group for each heme group. The equil. between pyridine hemochromogen and its components, pyridine and reduced heme, is complicated by the pptn. of reduced heme and the aggregation of pyridine hemochromogen. Hill's conclusion (*C. A.* 21, 595) that pyridine hemochromogen contains 2 pyridine groups is not considered to be proven. C. H. R.

**Capillary analysis of the secretions of the embryo and aleurone layer.** J. GRÜSS. *Wochschr. Brau.* 45, 539-42(1928).—Diastase and peroxidase are chemically bound. Peroxidase is the parent substance of diastase. The antioxi-dase found in the aleurone layer is not an enzyme; neither is it an albumin nor lipid. It belongs to the aromatic compds. The aleurone cells also secrete diastase plus peroxidase, cytase, invertase, pepsin and trypsin. The purpose of the antioxi-dase is to prevent the autooxidation of the diastase. A. SCHULTZ

**Combined sugar in serum albumin, egg white and the peptone solution.** KUNITARO KITAMURA. *J. Kyoto Prefectural Med. Coll.* 3, 20-4(1927).—K. examd. the presence of combined sugars in the above substance as a study of the nature of combined blood sugar. In the serum albumin from Kahlbaum free sugar is not contained, but there is 1.2-2.6% of combined sugar. In egg white there was found 0.428-0.536% of free sugar and 0.204-0.364% of combined sugar. In the Teruchi or Witte peptone there is 0.6-1.0% of free sugar, but there is no combined sugar, from which fact K. concludes that where there is combined sugar, there is always protein. K. SOMEYA

**Study of the fat-decomposing enzyme. XII. The activation of lipase by bile, and the relation between the stomach lipase and the activating action of bile.** KEN-SUKE GYOTOKU AND SEIKO MATSUBARA. *Tokyo J. Med.* 42, 2147-61(1928); cf. *C. A.* 23, 3724. —The splenic lipase of the dog is activated by the bile of man or of the dog. The activating action begins immediately after mixing, reaches a max. in 20-30 min., and then gradually decreases, until finally the activity becomes less than that of lipase to which no bile has been added. The weakening is more marked when the quantity of the added bile is smaller. With old bile, the activating action gradually decreases but it can cause no weakening of the lipase action after activating the lipase. The activating effect occurs at  $pH$  5-8.6 and is most intense at about  $pH$  7.6, decreasing rapidly when this point is passed. With unactivated specimens the influence of the  $H$ -ion concn. is small. The stomach lipase is also activated to a marked extent when purified; so various lipases cannot be differentiated by the presence or absence of the activating action. The activating agent of the bile is not dialyzable and resists heating, but dried bile dissolved in  $H_2O$  has no activating action. K. SOMEYA

The ideas of acidity, alkalinity and neutrality; their physico-chemical interpreta-

tion and their biological interest. L. HALLION. *Rev. prat. biol.* 21, 225-32(1928) --A detailed explanation, according to the general theories, of these terms for the benefit of the medical man. G. TOENNIES

Chemical change of Taka-diastase solution by heating. T. KAWAKAMI. *J. Pharm. Soc. Japan* 49, 346-55(1929).—Since com. Taka-diastase prepn. contains various enzymes besides the main active principle, proteolytic and amylolytic changes in Taka-diastase soln. were studied when the soln. was kept at a moderately high temp. At 65° or above no appreciable increase in alkali no. or formol no. was noted, showing that proteases do not act at such high temp. At 55°, the proteolytic change is most rapid, especially in the first 1-2 hrs. After 5 hrs. it slows up and nearly ceases after 6 hrs. At 45° the change is very slow and is still in action even after 80-90 hrs. At higher temps. the increase in formol no. is greater than that of alkali no., while at lower temps., the two nos. run almost parallel. Amylolytic change is evident even at such a high temp. as 75°, at which the reaction is very rapid and the rate of reaction decreases very rapidly. After 2 min. it decreases to  $\frac{1}{4}$ , after 6 min. to  $\frac{1}{50}$  and after 60 min. it entirely stops. NAO UYEI

Influence of tea and coffee on the amylolytic action of Taka-diastase. T. KAWAKAMI. *J. Pharm. Soc. Japan* 49, 356-61(1929).—Exts. of tea (both green and black), coffee and tannic acid or caffeine had no inhibitory influence on the hydrolysis of starch by Taka-diastase, if proper conditions were maintained during hydrolysis. N U

Influence of ultra-violet rays on the enzymic action of Taka-diastase. T. KAWAKAMI. *J. Pharm. Soc. Japan* 49, 361-5(1929).—Contrary to the statement of Pineussen and Renzo (*C. A.* 17, 1647; 18, 3068), no inhibitory influence of ultra-violet rays on the hydrolytic action of Taka-diastase was noted. K. used a quartz-Hg lamp as the source of the rays, using 10 times the voltage and amp. several times stronger than those used by P. and R. In order to avoid the influence of temp., irradiation was carried out at a distance of 40 cm. instead of 20, which was used by P. and R. No buffer was used to avoid the influence of rays on it. In samples where diastase soln. was cooled during irradiation no change in the rate of hydrolysis was noted for 4 hrs., whereas without cooling the rate of hydrolysis decreased very rapidly. NAO UYEI

The conditions of activation of washed zymin in relation to the coenzyme problem. A. A. STHERMAN. *Proc. Acad. Sci. Amsterdam* 32, 426-34(1929).—Zymin washed once with H<sub>2</sub>O in the ordinary way, when added to a soln. of glucose and K<sub>2</sub>HPO<sub>4</sub> caused no fermentation; re-activation was obtained by the addn. of AcH, methylene blue, hexose biphosphate or the "coenzyme" soln. (the clear soln. from once-washed zymin). The 1st washing of zymin extd. most of its hexose biphosphate; the second washing apparently extd. all of the biphosphate. This hexose biphosphate can serve as a hydrogen acceptor when in sufficient quantity, although it is supposed also to perform another more specific function. Zymin washed twice with water when added to a soln. of glucose and K<sub>2</sub>HPO<sub>4</sub> caused no fermentation; addn. of methylene blue or AcH had no effect; addn. of hexose biphosphate, however, produced a nearly quant. fermentation. It is considered that these two washings removed practically all the biphosphate, whose presence was essential to the fermentation. Fructose did not behave the same as glucose in this expt. although it did in the first. Zymin washed twice but more intensively than before was not activated by hexose biphosphate; it was necessary to make the further addn. of an ext. of zymin "free from coenzyme" or else to add some of the concd. washings, which latter are capable of fermenting glucose without any other accessory such as the hexose or potassium phosphate. In order to obtain the zymin ext., which is considered a "protein soln. free from coenzyme," zymin was washed 3 times with water and the proteins were extd. by boiling dil. potassium phosphate soln. Zymin washed 3 times would not ferment glucose even after the addn. of hexose biphosphate in large amts. and of the "protein solution free from coenzyme," while the addn. of the boiled washing still produced a fermentation. This indicates that, besides the 3 already known factors indispensable for a normal cell-free fermentation, at least one more must be added. In zymin subjected to 3 washings more intensive than the previous ones the zymase was inactivated so that even the addn. of the boiled washing would not reactivate it. R. P. WALTON

## C—BACTERIOLOGY

CHARLES B. MORREY

Effect of secondary rays from Lipiodol and bismuth subnitrate paste on *Staphylococcus aureus* and *Bacillus coli communis*. MARGARET E. FRIES AND MAURICE LENZ. *Proc. Soc. Exptl. Biol. Med.* 26, 14-16(1928).—Secondary rays emitted from BiONO<sub>2</sub> powder when exposed to x-rays inhibited the growth of *Staphylococcus aureus* and of *Bacillus coli communis*. Under similar conditions neither BiONO<sub>2</sub> paste nor Lipiodol (40% I<sub>2</sub>) inhibited the growth of these organisms. Possibly the fat interferes with the effect of the secondary rays. C. V. BAILEY

Effect of cholesterol activated by ultra-violet irradiation on growth of tubercle bacilli in vitro. ALAN R. MORITZ. *Proc. Soc. Exptl. Biol. Med.* 26, 43-4(1928).—No effect was detected. C. V. BAILEY

An endeavor to adapt a trypsin-susceptible bacteriophage to the action of trypsin. E. W. SCHULTZ AND E. A. GREEN. *Proc. Soc. Exptl. Biol. Med.* 26, 97-100(1928).—Possibly some increase in resistance to trypsin is acquired by the bacteriophage in the course of a number of serial exposures to suitable concns. of trypsin. C. V. B.

Inactivation of *Staphylococcus* bacteriophage by methylene blue. E. W. SCHULTZ AND A. P. KRUEZER. *Proc. Soc. Exptl. Biol. Med.* 26, 100-1(1928).—A no. of races of bacteriophage were tested as to their susceptibility to several dyes. No appreciable influence on any of the bacteriophages was noted with the single exception of the effect produced by methylene blue on 2 trypsin-susceptible *Staphylococcus* bacteriophages. These were completely inactivated in 6-12 hrs. by concns. of the dye as low as 0.002%. C. V. BAILEY

**Destruction of botulinus toxin by *Bacillus subtilis*.** C. N. STARK, J. M. SHERMAN AND PAULINE STARK. *Proc. Soc. Exptl. Biol. Med.* **26**, 343-4(1929).—In 14 da. *Bacillus subtilis* reduced the toxin titer of the botulinus filtrate from 300 M. L. D. to about 10 M. L. D. per cc. as detd. by guinea pig inoculations. C. V. BAILEY

**The bactericidal action of indole.** R. B. KILBORN, H. B. PIERCE AND R. P. TITTLER. *Proc. Soc. Exptl. Biol. Med.* **26**, 391-2(1929).—A soln. of indole 1-1000 filtered by pressure through a Seitz filter hindered the growth of all microorganisms studied. *Escherichia coli* was the most resistant; nevertheless its growth was prevented in the presence of 0.1% indole. *Salmonella paratyphi* was very susceptible to indole. *Escherichia typhi*, *Salmonella schotmulleri*, *Aerobacter aerogenes* and *Salmonella enteritidis* were also studied. C. V. BAILEY

**The isolation of *B. typhosus* from sewage and shellfish.** W. JAMES WILSON. *Brit. Med. J.* **1928**, I, 1061-2; *U. S. Pub. Health Eng. Abstracts* **E-660b**, 62-3(1928).—By the use of a new technic the presence of 1 typhoid bacillus in each cc. of Ballast sewage is demonstrated. The medium used was glucose-sulfite-Fe-Bi-brilliant green. Its efficacy depends on 2 factors: (1) *B. typhosus* in the presence of a fermentable carbohydrate is able to reduce a sulfite to a sulfide, and so to form a black colony in the presence of an Fe salt; (2)  $\text{Bi}_2(\text{SO}_4)_3$  in the presence of a certain excess of Na-SO, suppresses the growth of most coliform bacilli; in the presence of brilliant green, the selective action is intensified. Black colonies with a metallic halo are developed and also light green colonies. *B. typhosus* is sought among the black colonies. The green ones are *B. proteus*. The use of saccharose in a modified Endo medium enabled W. to distinguish rapidly between *B. typhosus* and those simulating it. The isolation of *B. typhosus* from enteric stools is one of the easiest procedures in applied bacteriology. The method has extremely important applications. C. R. FELLERS

**The efficacy of the lactobacteriotherapy from the chemical standpoint.** CARLOS A. SAGASTUME AND LUIS J. VIVIANI. *Semana med.* (Buenos Aires) **35**, 800 5(1928). As an index of the putrefaction in the intestine the reducing effect of  $\text{Fe}_2\text{O}_3$ , given by mouth, was investigated. Feces (0.2 g.) were dissolved in dil. HCl, heated on a water bath for  $\frac{1}{2}$  hr., cooled, filtered and 3 cc. taken 2 times. One part was first oxidized with  $\text{H}_2\text{O}_2$ , then 5 cc. of 3% KCNS soln. added to each and filled up to 25. The solns were compared colorimetrically. The ratio  $(\text{Fe}^{++}:\text{Fe total})$  multiplied by 100 is the index of putrefaction. A mixt. of the acid-forming bacilli is more efficient than *B. bulgaricus* or *acidophilus* alone. A. E. MEYER

## D—BOTANY

THOMAS G. PHILLIPS

**Action of several disinfectants on yeast.** FRED W. TANNER AND GEORGE D. BOULAS. *Proc. Soc. Exptl. Biol. Med.* 26, 154-6(1928).—Yeasts like bacteria are positive or negative to the Gram stain. Gram-positive yeasts are destroyed when stained for 1 hr. with 5 drops of a satd. aq. soln. of *gentian violet*; Gram-negative yeasts are also gentian violet-negative and are unaffected by this treatment. When the medium contains 1:80,000 gentian violet, positive fungi are destroyed; 1:140,000 inhibits growth. A tolerance can be developed. *Mercurochrome-220* sol. at a concn. of 0.4% destroys yeast cultures; a tolerance is not developed. *Tincture of iodine* (U. S. P.) in a diln. of 1:100 completely destroys yeast cultures; no tolerance is developed.

C. V. BAILEY

**Factors affecting penetration of methylene blue and trimethylthionine into living cells.** MATILDA MOLDENHAUER BROOKS. *Proc. Soc. Exptl. Biol. Med.* 26, 290-2 (1929).—Contrary to Irwin (C. A. 22, 4580), B. found only methylene blue present in the vacuole of living plants of *Nitella* and *Valonia* when the cells were placed in solns. contg. this dye. An analysis of the differences in methods used by Irwin and B. is given with particular reference to  $pH$  value, impurity of the dye, the concn. of dye in external soln., the presence of light and of injury to the cell.

C. V. BAILEY

**Mannitol agar in the differentiation of the fungi of the type blastomyces.** ALDO CASTELLANI. *Proc. Soc. Exptl. Biol. Med.* 26, 544(1929).—Ordinary agar to which 4% mannitol has been added is placed in extra large culture tubes. From 2 to 3 weeks later after inoculation and incubation at 26° certain *Blastomycoidea* produce black pigmentation, others occasionally pigment the medium, and still others produce no pigment. To the 1st group belong *B. immitis*, to the 2nd *B. dermatitidis*, and to the 3rd *B. tularensis*.

C. V. BAILEY

**A mannitol-fermenting Monilia.** ALDO CASTELLANI. *Proc. Soc. Exptl. Biol. Med.* 26, 544-5(1929).—More than 30 species of *Monilia* are known, none of which ferment mannitol. A fungus was recently isolated from sputum from a case of chronic bronchitis; it is unique in that it ferments mannitol with the production of gas. In addn. it ferments glucose, galactose, maltose, levulose and dextrin. The name *Monilia mannitofermentans* is suggested for this *Monilia*.

**Death from low temperature and resistance of plants to cold.** GUNNAR NILSSON-LEISSNER. *Quart. Rev. Biol.* 4, 113-7(1929).—A review.

J. B. BROWN

**Experimental chemical contributions to genetics.** HANS V. EULER, HARRY HELLSTROM AND DAGMAR RUNEHJELM. *Z. physiol. Chem.* 182, 205-17(1929).—Hybrids obtained by crossing mutants of barley representing strains with normal chlorophyll content and strains deficient in chlorophyll and subject to Mendelian cleavage were examined for catalase activity. The seeds were germinated in the dark and sep. detns. were made with the white and yellow seedlings. During the first 6-16 days of germination the yellow seedlings showed 2-3 times the catalase activity of the white ones. The same ratio was observed after drying, although the activity was thereby considerably diminished. In one series of hybrids the difference in activity diminished from the 8th to the 15th day, the white seedlings gaining more rapidly in catalase content until they practically equalled the yellow seedlings. The yellow pigment is xanthophyll, and when exposed to light the yellow seedlings rapidly become green. The transition from yellow to green pigment was followed spectroscopically by means of a microphotometer. Amylase and redoxase activity are also subject to Mendelian cleavage but the differences were found to be much less striking, while peroxidase activity differed only within the limits of individual variations.

A. W. DOX

**Slime staining.** PÁL LIPTÁK. *Magyar Gyógyszerészud. Társaság Értesítője* 4, 17-8; *Chem. Zentr.* 1928, I, 1559.—When sap or plant slimes were stained with phosphomolybdic acid soln. and  $I_2-ZnCl_2$ , the various cells were clearly differentiated.

FRANCIS P. GRIFFITHS

**Depsides.** ISMAEL ASTRADA. *Rev. centro estud. farm. bioquim.* 16, 437-46(1927); *Chem. Zentr.* 1928, I, 1551.—According to Fisher and Freudenberg, depsides are tannin-like substances contg. a pyrogallol group. The following plants contain depsides: flowers of the red rose; nutgall; bark and leaves of witch-hazel; leaves of the walnut.

FRANCIS P. GRIFFITHS

**The ether-soluble substances of cabbage leaf cytoplasm. V. The isolation of  $n$ -nonacosane and di- $n$ -tetradecyl ketone.** HAROLD J. CHANNON AND ALBERT C. CHIBNALL. *Biochem. J.* 23, 168-75(1929); cf. C. A. 22, 1790.—When acetone is added to an ether fraction, the ppt. contains not only true phosphatides, but 2 other sub-

stances which do not contain P. The latter can be sepd. from the true phosphatide fraction by extn. with boiling acetone. On cooling, they sep. in cryst. form, and it is shown that the main constituents are *n*-nonacosane,  $C_{29}H_{60}$ , and di-*n*-tetradecyl ketone,  $C_{14}H_{30}$ ,  $CO.C_{14}H_{28}$ . VI. Summary and general conclusions. ALBERT C. CHIBNALL and HAROLD J. CHANNON. *Ibid* 176-84.—220 g. of material contains (in g. chlorophyll ( $\alpha$  and  $\beta$ ), 20.5; carotin, 1.1; xanthophyll, 1.7; Ca phosphatide, 40.6; unidentified Ca salts, 11.3; unidentified Fe compd., 6.7; glycerides and waxes contg. palmitic, stearic, linolic and linolenic acids, 38.3; glycerol, 2.8; unsaponifiable matter, satd. fraction, chiefly nonacosone and di-*n*-tetradecyl ketone, 27.0; sterols (by digi-tonin), 9.8; unidentified products, probably alcs. and hydrocarbons, 29.2

Nature of the pectic substances of flax. A preliminary investigation. BENJAMIN HARKOW and FREDERICK W. NORRIS. *Biochem. J.* 23, 195-8(1929).—The results obtained favor the ring formula for pectic acid, suggested by Nanji, Paton and Ling (cf. *C. A.* 19, 2327), rather than the galactose-tetragalacturonic acid formula of Henderson (cf. *C. A.* 23, 1118)

The state of iodine in *Falkenbergia doubletii* Sauv. E. CHEMIN. *Bull. soc. botan. France* 75, 540-2(1928).—Upon the addn. of starch to a slightly alk. 1% soln of KI a blue color is not formed. Acidifying this soln. with  $H_2SO_4$ , HCl, or  $HNO_3$  produces a blue color. Using tissue of the alga, *Falkenbergia doubletii* Sauv., instead of starch and KI in the above reaction gave similar results. It is concluded, therefore, that I in alga tissue is in the combined state and that volatilization does not occur as a normal function. Certain positive tests for the presence of  $I_2$  are probably the result of an instantaneous chem. reaction during which  $I_2$  is liberated. A. E. HITCHCOCK

Potash requirements of the opium poppy. J. GAROLA. *Ann. sci. agron.* 46, 169-75 (1929).—In order for the opium poppy (*Papaver somniferum*) to attain its full development, it is necessary to make a large quantity of potash available toward the end of the vegetative state. A rapid fixation of potash occurs at flowering. K. S. M

Evolution of hydrocyanic acid by ferns. ALFRED HEILBRONN. *Ber. deut. botan. Ges.* 47, 230-3(1929).—Tissue of *Polypodium aureum* var. *tetraploidea* when subjected to a temp. of  $-17^\circ$  for 5 min. and then brought to room temp. gave off the odor of HCN, the presence of which was verified by tests with Na picrate and the Berlin blue reaction of Treub. Maseration without freezing also liberated HCN. A comparison with *Prunus laurocerasus* on the effect on *Drosophila melanogaster* indicated that the amt. of HCN present is about half that of this species. LAWRENCE P. MILLER

Fermentation and respiration in chlorophyllous plants. L. GENEVOIS. *Rev. gén. botan.* 40, 654-74, 735-44(1928); 41, 49-63, 119-28, 157-84, 252-71(1929); cf. *C. A.* 22, 1791.—Manometric methods, essentially those of O. Warburg (*Stoffwechsel der Tumoren*, 1926), were used. Respiration and fermentation were studied in the following algae, *Chlorella pyrenoides* Chick, *Scenedesmus basilensis* Chodat, *Coclostrium proboscideum*, *Haematococcus pluvialis*, *Stichococcus bacillaris*, *Pseudonocardium basilense* Vischer. In detg. the effects of various chemicals on the intensity of respiration ( $I_0$ ), larger differences were obtained if the algae used were grown under sub-optimum conditions as regards nutrition and light. By working largely with *Chorella* it is shown that substances contg. a C=O group, i. e., fermentable sugars, fatty acids, aldehydes, amino acids and keto acids, increase  $I_0$ . The effect is largely independent of the concn., and the no. of mols. oxidized per unit of time, calcd. from the O consumed, is a decreasing function of the mol. wt. In mixts. of 2 substances the net effect is intermediate between either one and can be calcd. from the no. of mols. of each substance present. These substances serve as nutrient materials while certain dyes as methylene blue, thionine, neutral red, and safranin, increase  $I_0$  through some catalytic action. The effect remains even after the excess color has been washed from the cells. If glucose and a dye are both present the effects are additive. Results with species other than *Chorella* were similar except that with *Haematococcus*  $I_0$  was not increased but was even depressed by substances contg. a C=O group, while the dyes were stimulating, although feebly so. KCN decreased  $I_0$ . Under anaerobic conditions in the presence of sugar fermentation takes place. When the respiration was stopped by KCN fer-

mentation in air ( $F_{CO_2}^O$ ) was equal to that in N ( $F_{CO_2}^N$ ) and to that in N without KCN. Fermentation and respiration in *Lathyrus odoratus* in different plant organs in various stages during the life cycle were studied. Values for  $I_0$  and  $r_{CO_2}^N$  were high in embryonic tissue. Respiration is considered as consisting of 2 phenomena, one of oxida-

tion and the other a synthesis of carbohydrates from the products of fermentation. The latter is known as the reaction of Pasteur (Meyerhof). By use of the proper concn. of KCN it was possible with *Lathyrus* to arrest the reaction of Pasteur without stopping respiration. Results are discussed from the point of view of the similarity between the relations of fermentation and respiration in both plant and animal tissue.

LAWRENCE P. MILLER

Studies on the growth of root hairs in solutions. IX. The  $p_H$  molar rate relation for collards in calcium nitrate. CLIFFORD H. FARR. *Ann. Missouri Bot. Gardens* 16, 53(1929); cf. *C. A.* 23, 3487.—A study was made of the root and root hair elongations of collards grown in solns. of  $\text{Ca}(\text{NO}_3)_2$  and  $\text{CaCl}_2$  at various  $p_H$  values. The curves obtained for max. rate of root hair and of root elongation and for max. length of root hairs correspond to those for av. root hair elongation. A complete condensation of data shows the influence of  $p_H$  in each of the salt concns. used, with important differences in the growth and appearance of the plants.

N. M. NAYLOR

Some chemical and physiological studies on the nature and transmission of infectious chlorosis in variegated plants. EVERETT F. DAVIS. *Ann. Missouri Bot. Gardens* 16, 145(1929).—Hydrogen-ion detns. were made on the juices of green areas and of chlorotic areas of the leaves of *Evonymus japonica* vars. *aurea*, *argenteo* and *medio-picta*. Chlorotic areas of all varieties except *aurea* were higher in initial acidity than were the green areas. The  $p_H$  of the juice decreases in direct proportion to the time in min. of exposure to air. The total acidity of the juice of green leaves increases on exposure to air, but not that of the juice from chlorotic areas. These observations are discussed in the light of their botanical significance.

N. M. NAYLOR

Spectrophotometric studies of penetration. V. Resemblances between the living cell and an artificial system in absorbing methylene blue and trimethylthionine. MARIAN IRWIN. *J. Gen. Physiol.* 12, 407-18(1929); cf. *C. A.* 22, 4580.—The living plant cell may be represented by the following diagram: aq. sap in vacuole | vascular interface | non aq. protoplasmic layer | external interface. Dye penetration was studied in an artificial system consisting of (1) the same dye solns. as were used for the living cells; (2)  $\text{CHCl}_3$  to represent the non-aq. protoplasmic layer; (3) sap freshly extd. from living cells or artificial sap.  $\text{CHCl}_3$  is only a crude representation of the non-aq. layer; therefore the system may resemble the living cell only qualitatively. The artificial system and the living cell behave alike toward methylene blue and azure B (trimethylthionine) which supports the idea that there is a non-aq. layer in the cell protoplasm. A close resemblance between penetration of these dyes into *Valonia* cells and into the artificial system at  $p_H$  9.5 was noted. In *Nitella* cells, however, at  $p_H$  9.2, the sap in the artificial system takes up relatively more azure B from methylene blue soln., in which it exists as an impurity, than does the vacuole of the living cell. Both the living cell and the artificial system take up azure B much more rapidly than methylene blue. A comparison of the 2 systems at  $p_H$  5.5 cannot be made because injury to the living cell occurs before the dye penetrates in quantities sufficient for analysis. The resemblances between *Valonia* and *Nitella* become less as cell injury increases owing to the penetration of methylene blue into the vacuoles of the injured cells.

C. H. RICHARDSON

The penetration of strong electrolytes. W. C. COOPER, JR., M. J. DORCAS and W. J. V. OSTERHOFF. *J. Gen. Physiol.* 12, 427-33(1929).—The entrance of strong electrolytes into *Valonia* is very slow unless the cells are injured. They may penetrate largely as undissoc. mols. formed at the surface of the protoplasm by the collision of ions. KCl may be adsorbed to the extent of  $3 \times 10^{-8}$  mols. per hr. per sq. cm. surface. Preliminary expts. showed that a no. of other substances penetrate to some extent. In sea water the sp. gr. of which was increased by the addn. of  $\text{CsCl}$ , *Valonia* floated for over a year without penetration of Cs except as the result of injury. The penetration of  $\text{NH}_4\text{Cl}$  decreases the sp. gr. of the sap, causing the cells to float, under which conditions they live indefinitely. Probably  $\text{NH}_3$  or  $\text{NH}_4\text{OH}$  penetrates as such and is then changed to  $\text{NH}_4\text{Cl}$ .

C. H. RICHARDSON

Respiration and geotropism in *Vicia faba*. I. A. E. NAVEZ. *J. Gen. Physiol.* 12, 641-67(1929).—Seedlings of *V. faba* give a const. secretion of  $\text{CO}_2$  over fairly long periods if the temp. is controlled very accurately. The  $Q_{10}$  ratio, derived from the exptl. data, is not const.; the value for  $\mu$  (Arrhenius formula), 16,250, is consistent with values previously obtained for  $\mu$  in respiratory oxidative processes in similar organisms. The relation between the reaction time for the geotropic curvature of the root of *V. faba* and temp. was also calcd. from the Arrhenius formula,  $\mu$  being 16,110, which stands in quant. agreement with values deduced from earlier similar data. It

is believed that a respiratory oxidative process controls the onset of geotropic curvature.

C. H. RICHARDSON

**Origin of ethereal oils in plants.** L. FRANCESCONI. *Rivista ital. essenze profumi* 10, 33-6(1928).—Lemongrass oil contains citral, citronellal, geraniol, linalool, dipentene, methylheptenone and capraldehyde. Pelargonium essence contains citronellol, linalool, geraniol, rhodinol, citral, menthone, isoamyl alc. and valeric acid. The presence of isoamyl alc. or better of isovaleric acid confirms the transitory existence of citronellal. From the isoamyl alc. can be obtained isovaleraldehyde and citronellal. The formation in the plant can be proved by the presence of citronellol and menthone. If the formation speed of isovaleraldehyde and citronellal is small, that of the trans formation of this into citronellol, geraniol and menthone is large. Lab. reactions prove that menthone is formed from rhodinol. Citronellal is converted directly to rhodinol and to menthone through a ring closure. This is confirmed by the presence of rhodinol in pelargonium oil. Rhodinol is therefore also admissible. This would be a transition product that on reduction goes to rhodinol and by condensation to menthone. Rhodinol on oxidation in the plant again forms rhodinol, which passes to menthone, formed at the time of flowering, when the quantity of O fixed by the tissues is noteworthy. Rhodinol is, therefore, a reserve material for the genesis of rhodinol, menthone and citronellal. Among the components of pelargonium essence are also pinene, phellandrene and tiglic acid. From the hydration of geraniol and successive elimination of water pinene originates.

R. SANSONE

**Origin of ethereal oils in plants.** L. FRANCESCONI. *Rivista ital. essenze profumi* 11, 78-83(1929).—To detect isovaleric acid in lemon juice, shake 20 cc. in a separatory funnel with an equal quantity of 10%  $\text{Na}_2\text{CO}_3$ , ext. the alk. soln. with ether to eliminate the essence, decompose the Na salts by distg. with  $\text{H}_2\text{SO}_4$ , neutralize the distillate with  $\text{Ba}(\text{OH})_2$ , eliminating excess with  $\text{CO}_2$  in the warm, and filter. Use a part of this soln. for pptn. reactions. Evap. the rest to dryness, redissolve in a little  $\text{H}_2\text{O}$  and filter. Evap. a few drops of this soln. and compare the residual crystals with those of Ba valerate. On a little of the residue a drop of concd.  $\text{H}_2\text{SO}_4$  develops the odor of valeric acid, and on adding  $\text{EtOH}$  the odor of Et valerate. In the essence was found isovaleraldehyde. An aq. ext. of the integral lemon juice (20 cc. essence and 10 cc.  $\text{H}_2\text{O}$ ) gave a reaction with Fe alum for isoamyl alc. These components are intermediate substances for the formation of other more useful products. Genetic plans are given for lemon juice, mandarin oil, orange oil and bergamot oil.

R. SANSONE

**Some properties of the laminarin from Laminaria.** H. COLIN AND P. RICARD. *Compt. rend.* 188, 1449-51(1929); cf. *C. A.* 9, 1923; 16, 722; 17, 2291.—Aq. exts of 38 kg. *Laminaria flexicaulis* were boiled with  $\text{Ba}(\text{OH})_2$ , the excess was removed and the laminarin was pptd. by  $\text{EtOH}$ . The dry product was repeatedly cold extd. with 85%  $\text{EtOH}$ , dissolved in  $\text{H}_2\text{O}$ , defecated by Pb and finally pptd. with  $\text{EtOH}$ . Repeated repptns. yielded a product free of mannitol and contg. only 0.6% ash. The yield is 400 g. The substance crystallizes in the form of slightly doubly refractive spherulites. The formula  $(\text{C}_6\text{H}_{10}\text{O}_5)_x$ ,  $x$  being 6 or 7, is probable.  $[\alpha]_D^{25} = 11.5$ . After acid hydrolysis  $[\alpha]_D = 49^\circ$ . Only glucose was found after hydrolysis. The substance does not melt; it begins to turn brown at  $200^\circ$ . The anhyd. product reabsorbs 16.5%  $\text{H}_2\text{O}$  in 3 days without change of appearance. Twenty-one g. is sol. in 100 g.  $\text{H}_2\text{O}$  at  $15^\circ$ ; 16.5 g. is sol. in 100 g. 60%  $\text{EtOH}$ , insol. in 85%  $\text{EtOH}$  even on boiling. The Ba deriv. is sol. in  $\text{H}_2\text{O}$  and pptd. by  $\text{EtOH}$ ; it is not decompd. by  $\text{CO}_2$ .

G. TOURNIES

**A chemical study of the rind of California oranges.** MARION B. MATLACK. *J. Am. Pharm. Assoc.* 18, 24-31(1929).—The peel was freed as far as possible from extraneous material and subjected to the usual methods for plant analysis. Oleic, linoleic, linolenic, stearic and palmitic acids were found in the form of their glycerol esters. Two phytosterols were isolated. One appears to be sitosterol and the other  $\beta$ -phytosterol. A phytosterolin was obtained apparently identical with sitosterol  $d$ -glucoside. Ceryl alcohol, small amts. of resin and carotinoid coloring matter were identified.

L. E. WARREN

**The exchange of ions between yeast cells and solutions of ammonium chloride.** PAUL GENAUD. *Compt. rend.* 188, 1513-4(1929).—If living yeast is bathed with a soln. of  $\text{NH}_4\text{Cl}$  at  $p_H$  7 the following facts appear: (1) The concn. of Cl ions does not change; (2) the concn. of  $\text{NH}_4$  ions in the soln. diminishes from  $n_0$  to  $n_1$  ( $n_1/n_0$  is const. for all concns. of  $\text{NH}_4\text{Cl}$  and of yeast cells, and  $(n_0 - n_1)$  is const. for all concns. of yeast, but increases with the concn. of  $\text{NH}_4\text{Cl}$ ); (3) K and Ca appear in the soln., and their am. is approx. equal to  $(n_0 - n_1)$ . The living cell behaves like an inert insol. salt, of

which the anion is always insol., and of which the cation undergoes exchange with the cations of the soln. In this respect it in general obeys the law of mass action.

J. J. WILLAMAN

**Function of caffeine in the metabolism of *Ilex paraguayensis* St. Hil.** T. WEEVERS. *Proc. Acad. Sci. Amsterdam* 32, 281-7(1929).—This plant contains caffeine and not matein, as formerly supposed. It occurs as the xanthine deriv. in leaves and bark, but is absent from wood and fruit. During the growth of the leaves the relative quantities decrease, but the abs. amt. increases. After full growth there is a marked decrease, so that 2-year old leaves contain only half as much as those 1 year old. This is not brought about by migration to the bark, but is a result of its consumption during metabolism. Excised leaves placed in water lose caffeine in the light, but gain it in the dark.

J. J. WILLAMAN

**Function of alkaloids in the leaves of *Cinchona succiruba* Pavon.** T. WEEVERS AND H. D. VAN OORT. *Proc. Acad. Sci. Amsterdam* 32, 364-70(1929).—Brief expts. are described which indicate that the alkaloids increase in the leaves in the dark, especially in excised ones. The authors' interpretation is that the alkaloids are products of degradation processes, probably of protein metabolism.

J. S. H.

**The antimony trichloride reaction of liver oils.** HANS V. EULER, MARGARETA RYDBOM AND HARRY HELLSTRÖM. *Biochem. Z.* 208, 73-8(1929).—Extn. of liver oil with 96% EtOH increases the intensity of the SbCl<sub>3</sub> reaction. After double extn. the color intensity is 4 times as great as that of the original oil. The absorption band at 320 mμ is characteristic for the vitamin A. Other fats and oils contg. carotinoids beside the liver oils can likewise be enriched in carotinoid, whereby inactive substances are removed.

S. MORGULIS

**The iodine factor in animal nutrition.** FRANK F. CORRIE. *Pharm. J.* 121, 181-2(1928); cf. *C. A.* 22, 286, 1995, 2219.—The relation of I to growth and resistance to disease in animals is shown.

S. WALDBOTT

**Test for vitamin A in margarine, butter and other fatty foods (ANDERSEN, NIGHTINGALE) 12.** New paths of therapy [vitamins] (HOFMAN) 17. Addition of SbCl<sub>3</sub> and SnCl<sub>4</sub> to unsaturated hydrocarbons [vitamin A color reaction] (VON EULER, HELLSTRÖM) 10.

## F—PHYSIOLOGY

E. K. MARSHALL, JR.

**Behavior of the diastase in the blood, urine, and feces of the dog before and after ligation of the pancreatic ducts.** P. GALLI. *Folia clin.* 3, 120-33(1928); cf. *C. A.* 23, 646. In dogs with the pancreas intact, the amt. of diastase in the blood is always greater than that in the urine, but the max. and min. values in the 2 cases never correspond. Ligation and resection of the pancreatic ducts always cause very great increases of the amts. of the enzyme in the blood and urine, but here again no fixed relationships are observed; with the blood this increase persists a week after the ligation, but the diastase content of the urine gradually diminishes. The lack of pancreatic secretion in the intestine causes the disappearance from the feces of the amylolytic enzyme, which is not found in the feces a week after the ligation.

B. C. A.

**Does a gastric lipase exist?** G. MELLI AND M. RADICI. *Folia clin.* 3, 169-90(1928).—The authors conclude that the lipase, the existence of which in the gastric juice is affirmed by some and denied by others, is actually the lipase which occurs normally in the gastric mucosa and leaves this accidentally as a result of trauma following probing. The functions of this lipase are probably limited to the interior of the individual cells. The stomach plays no part in the digestion of fats.

B. C. A.

**Pancreatic secretion.** R. CARUSI. *Folia clin.* 3, 209-55(1928).—An internal and an external pancreatic secretion exist, but changes in the secretions are not always accompanied by corresponding histological changes. The external secretion is composed of trypsin, lipase and amylase. The internal secretion is produced by the islets of Langerhans and is able to act on carbohydrates. The various methods suggested for detg. the enzymes are discussed and a modified method for detg. amylase is given.

B. C. A.

**Secretions of digestive glands and blood chemistry. I. Alkali reserve and chlorides in blood.** S. I. PRIKLADOVITZKII AND M. P. BRESTKIN. *Russ. J. Physiol.* 11, 445-69(1928).—Normal digestive activity causes a fluctuation in the alkali reserve depending on the kind of food taken. Feeding with lean meat raises the alkali reserve in the course of the first 2 hrs. It gradually returns to its initial value. It is also raised by feeding white bread. Feeding with fat causes a fall followed by a rise. Fluctuations of alkali reserve in the course of digestion are generally accompanied by inverse fluctuations of the chloride content of the blood.

The adrenal glands. G. N. STEWART. *Arch. Internal Med.* 43, 733-66(1929).—A lecture.

Underlying disturbances of metabolism of the nervous child. HECTOR C. CAMERON. *Brit. Med. J.* 1929, I, 185-7.—A lecture.

Chemical factors in the control of the circulation. H. H. DALE. *Brit. Med. J.* 1929, I, 1093-6.—A lecture.

Factors which influence tryptic digestion in the intestine. H. J. VONK AND H. P. WOLVEKAMP. *Z. physiol. Chem.* 182, 175-200(1929).—Statements in numerous textbooks that protein digestion in the intestine occurs at about  $p_H$  8, the optimum for trypsin, are erroneous. The reaction of the intestinal contents is practically neutral, the variations being more frequently on the acid than on the alk. side. Two factors facilitate digestion at a  $p_H$  below the optimum. The first of these is the continual movement and kneading of the mass undergoing digestion in the intestine. The same effect is obtained *in vitro* by mech. stirring. This effect is sufficient to compensate the unfavorable influence, in the case of fibrin, of a deviation of 2 units from the  $p_H$  optimum. It is not a specific effect, since it increases the reaction velocity even at the optimum  $p_H$ . The 2nd factor, which is probably specific, is the activation of the action of trypsin on solid protein at slightly acid reaction through the agency of the bile salts. At  $p_H$  6 the digestion velocity in the presence of  $1/20$  vol. of bile is equal to that at  $p_H$  8 in the absence of bile. In low concns. the effect of bile, Na taurocholate, or the multivalent ion of  $K_4Fe(CN)_6$  is slightly inhibitory; at high concns. the effect is a marked acceleration. The influence of bile on the digestion of Witte peptone is negligible. The optimum here for trypsin is much broader, and the difference between  $p_H$  7 and  $p_H$  8 is insignificant. Other possible factors that might compensate the unfavorable  $p_H$  of digestion *in vivo* are the continual removal of cleavage products by active absorption through the intestinal wall, a possible change thereby in the  $p_H$  optimum, and the continual supply of fresh enzyme. None of these factors is present in the usual digestion expts. *in vitro*. In the digestion of Witte peptone by trypsin a peculiar minimum was consistently noted at  $p_H$  7.6, for which no explanation is offered.

Resorption of cerebrospinal fluid through the choroid plexus. H. S. FORBES, F. FREMONT-SMITH AND H. G. WOLFF. *Arch. Neurol. and Psychiat.* 19, 73-7(1928)

The normal blood of some domesticated animals. C. E. HAYDEN AND P. A. FISH. *Cornell Vet.* 18, No. 2, 197-203(1928); *Expt. Sta. Record* 59, 876.—Detns. were made for sugar, urea, uric acid, total nonprotein N, creatinine, chlorides, Ca, inorg. phosphates, acid-sol. phosphates, n, and the serum protein of the blood of the cow, goat and chicken, as well as the hemoglobin, erythrocyte and leucocyte counts, including the differential count of the leucocytes.

Blood sugar in the normal child in earliest infancy. M. ACUNA AND P. WINOCTR. *Rev. especialidades* 3, 5-15(1928); *Physiol. Abstracts* 13, 523.—In 54 normal infants the av. blood sugar was 0.0933 g. %, the lowest 0.061 %, the highest 0.114 %.

The distribution of residual nitrogen in human blood. HERMANN STEINITZ AND HERMANN SIMCHOWITZ. *Klin. Wochschr.* 8, 732-4(1929).—Residual N as detd. on whole blood is, usually, not very different from that detd. in the serum or plasma. The values fluctuate considerably. Sometimes the whole blood gives higher values; sometimes it is the serum.

The behavior of young and of old animals toward asphyxiation. M. REISS AND F. HAUROWITZ. *Klin. Wochschr.* 8, 743(1929).—Old mice succumb rapidly in an atm. of  $CO$ ,  $H_2$  or  $CO_2$ . Young animals survive a long time under the same conditions. Old mice die rapidly from a lethal dose of strychnine or after their necks are placed in a clamp. Young mice live a long time under these conditions. Ten mg of HCN kills old mice in a few seconds. Young mice survive for 80 min.  $CHCl_3$  kills mice with equal rapidity regardless of age.

**Isolation of methylglyoxal as an intermediary substance in glucolysis.** MARTHA VOGT. *Klin. Wochschr.* 8, 793-4(1929).—This is an extension to animal tissue of the work of Neuberg and his co-workers on yeast. Digestion of muscle, liver or kidney of pigs or rabbits with water removes the coenzyme almost completely and leaves apozymase in the insol. residue. The apozymase converts hexose diphosphate into methylglyoxal. Apozymase does not convert glucose into methylglyoxal. The enzyme that converts glucose into hexose diphosphate is either destroyed or extd. in prepg. the material. Coenzyme converts methylglyoxal into lactic acid. Methylglyoxal is produced from hexose diphosphate by animal tissue only when the coenzyme is destroyed or extd.

MILTON HANKE

**Preparation of a substance that reduces the calcium content and one that reduces the phosphate content of serum.** II. Demonstration in the spleen and in the lymph glands. A. NIRSCHKE. *Klin. Wochschr.* 8, 794(1929).—It is possible, by suitable extn. methods, to obtain a substance from the thymus gland which, when injected into animals, reduces the Ca content of the serum to an av. of 7 mg. % and leads to tetany and elec. hyperexcitability. Another substance can be isolated that has no effect upon the Ca but that reduces the P content of the serum by 50% without producing any systemic effects. Since extirpation of the thymus does not, regularly, lead to systemic effects, it was conjectured that certain other of the body glands may have a function similar to that of the thymus. This conjecture has been verified. Exts. have been prepd. from spleen and lymph glands that are identical in properties with those described above for thymus.

MILTON HANKE

**The action of gas mixtures containing carbon dioxide on the respiration.** A. VIETHEN AND F. GRÜNEBERG. *Klin. Wochschr.* 8, 887(1929).—Air or O that contains 1% of CO<sub>2</sub> has no effect upon respiration in children past 6 yrs. of age. In younger children the respiratory vol. may be increased 33 to 50%. A mixt. contg. 2 or 3% of CO<sub>2</sub> is effective at all ages. Lung vol. is increased 50-100%. The respiratory rate is not increased. A mixt. contg. 4% of CO<sub>2</sub> increases the respiratory vol. 100-150%. The respiratory rate is also increased.

MILTON HANKE

**Creatine-creatinine excretion and serum calcium in normal male children.** M. KARSHAN, R. G. FREEMAN, JR., AND E. G. MILLER, JR. *Arch. Pediatrics* 46, 323-6 (1929).—The subjects were male children 5-9 yrs. of age. They were tonsil-adenoid patients and were clinically normal otherwise. In a series of 54 cases, the creatine of the urine, expressed as % of the total creatinine, was from 2.1 to 62.9. In a series of 72 cases, the Ca content of the blood serum in the post-absorptive state ranged between 9.3 and 13.2 mg. per 100 cc. Age made no significant difference. The creatine-creatinine metabolism in a given child varied from day to day.

J. S. H.

**New theory of the chemistry of blood clotting.** RUSSELL C. ERB. *Catalyst* 14, No. 6, 14-5(1929).—When horse blood is drawn, a clot forms after the leucocytes have become coned. In the animal, clotting is initiated by a localized and intense leucocytosis. The leucocytes then supply thrombogen in such quantities that the antagonistic action of heparin is overcome; the Ca ions then produce active thrombin which immediately converts fibrinogen into fibrin.

JOSEPH S. HEPBURN

**Loss of water and salts through the skin, and the corresponding physiological adjustments.** W. HANCOCK, A. G. R. WHITEHOUSE AND J. S. HALDANE. *Proc. Roy. Soc. (London)* B105, 43-59(1929).—Loss of H<sub>2</sub>O through the skin is due partly to evapn of H<sub>2</sub>O which passes through the skin by osmosis, and partly to sweating; the latter process is commonly in complete abeyance in temperate or cold climates. Insensible perspiration is entirely independent of sweating. Loss of H<sub>2</sub>O, when small, occurs by osmosis and evapn. When the loss becomes marked, true sweating occurs, the loss of chlorides increases, and the ratio NaCl:KCl becomes approx. 9:1. The chloride anion content of true sweat increases markedly with the duration of sweating, and, to a lesser extent, with the available NaCl or KCl in the body, and with a reduction in the supply of H<sub>2</sub>O; it is always lower than in blood plasma, and is reduced only slightly by abundant ingestion of H<sub>2</sub>O or by reduction of the supply of chlorides in the body. The sweat glands have a very limited role in the regulation of the compn. of the blood plasma; and their secretion is always hypotonic.

JOSEPH S. HEPBURN

**Glutathione, cytochrome and hydrogen-ion concentration in developing chick embryos.** H. YASU. *Japan Med. World* 9, 38-41(1929).—A gradual increase in the glutathione content is evident during the first half of the developmental period, reaching a max. on the 12th to the 14th day, after which there is a gradual decrease. This holds true for sep. organs as well as for the whole chick embryo. Cytochrome was found in negligible quantity from the 4th to the 11th day of incubation, the period of very rapid growth. It is only at the beginning of development of tissue that it is

relatively acid. Then it becomes more alkaline until the 14th or 15th day, when it becomes still more alkaline and reaches the final constant  $p_H$  value. N. KOPELOFF

**Investigation of glycogen of the inner ear.** HYOSAKU TANAKA. *Sei-I-Kwai Med. J.* 48, No. 1, 33-45, Abstract Sect. 2-3(1929); cf. *C. A.* 23, 3498.—The conclusions of previous work are summarized. W. D. LANGLEY

**The solubility of gases in blood and blood fluids.** ARTHUR GROLLMAN. *J. Biol. Chem.* 82, 317-25(1929).—The solubilities of  $C_2H_4$  at varying pressures in  $H_2O$ , dog blood plasma and dog hemoglobin solns. follow Henry's law. The blood lipoids increase the soly. of  $N_2$ ,  $C_2H_2$  and  $C_2H_4$  in aq. solns. The soly. of  $C_2H_2$  in human, dog and rabbit blood and blood fluids is much more const. than that of  $C_2H_4$ ; this difference is undoubtedly due to the much greater soly. of  $C_2H_4$  in lipoids. A. P. LOTHROP

**Does cabbage fed to rabbits increase serum calcium?** ROBERT KAPSINOW AND FRANK P. UNDERHILL. *J. Biol. Chem.* 82, 377-84(1929).—Although there were occasional indications that cabbage may have an effect in raising the serum Ca, they were too vague to state definitely that cabbage contains a substance analogous to the parathyroid hormone in its effect on serum Ca. Daily bleedings in rabbits have a severe effect and the 5 cc. necessary for a Ca detn. may possibly have interfered with a consistent effect produced by cabbage. The specific Ca action of cabbage was restudied because of Culhane's conclusions (*C. A.* 22, 267) that cabbage definitely raises the serum Ca of rabbits. A. P. LOTHROP

**Benzoylated amino acids in the animal organism. IV. A method for the investigation of the origin of glycine.** WENDELL H. GRIFFITH. *J. Biol. Chem.* 82, 415-27(1929); cf. *C. A.* 20, 2875.—In the urine of rats following the ingestion of  $BzONa$  hippuric acid constituted 66-95% of the total  $BzOH$ ; it was, therefore, the principal product in the detoxication of the ingested  $BzONa$ . Survival and growth of young rats on diets contg.  $BzONa$  occurred only when these diets furnished a supply of glycine or precursors of glycine which was adequate for the detoxication of the  $BzONa$  and for the formation of new tissue proteins. The rate of growth of young rats on a diet contg.  $BzONa$  can be used in detecting the presence of glycine or its precursors in the diet and this method is being used in a study of the origin of glycine in the animal organism. A. P. LOTHROP

**The specificity of the intracellular dehydrogenases. II. The effect of poisons upon the dehydrogenase systems of frog and of fish muscle.** MARY E. COLLETT AND MIRIAM F. CLARKE. *J. Biol. Chem.* 82, 429-33(1929); cf. *C. A.* 22, 4177.—Selenite, arsenate, phenol and benzoate were used with 5 donators, succinic, glycerophosphoric, *l*-malic, lactic and citric acids. "Poisons, which with fish muscle show the same order of toxicity with the donators studied, vary significantly in toxicity with frog muscle. As these variations are not due to poison-donator reactions, they must be due to poison-enzyme reactions, and therefore indicate the presence of at least 3 specific dehydrogenases; viz., citric, glycerophosphoric and lactic." III. **The dehydrogenases of frog muscle.** MARY E. COLLETT, MIRIAM F. CLARKE AND JOYCE MCGAVRAN. *Ibid* 435-7.—Since the reaction time for decolorization of methylene blue is hastened by the addn. of a second donator in optimum concn., it follows that frog muscle contains specific dehydrogenases, one for each of the 5 donators tested. A. P. L.

**Chemical studies of muscle contracture. III. The change in glycogen during shortening produced by tetanus toxin.** H. A. DAVENPORT, HELEN K. DAVENPORT AND S. W. RANSON. *J. Biol. Chem.* 82, 499-504(1929); cf. *C. A.* 23, 424, 3257.—The glycogen content of guinea pig and rabbit gastrocnemii is usually reduced by tetanus toxin in the early stages of contraction but in rats there is little change under the same conditions. Contractures resulting from dorsal root section of spinal nerves show no change in glycogen. The variability in reaction among different species and during different stages of tetanus contracture indicates that it does not have a cause and effect relationship to the contracture. There is no change produced in glycogen content by tetanus toxin in denervated muscles. A. P. LOTHROP

**The automatic regulation of gastric acidity.** HUGH MACLEAN AND W. J. GRIFFITHS. *J. Physiol.* 66, 356-70(1928).—The concn. of  $HCl$  in the normal stomach is regulated automatically by the  $p_H$  of the gastric juice. The presence of a certain  $p_H$  in the stomach inhibits secretion of acid, with the result that a neutral fluid containing chloride is secreted which, by diln., reduces the acidity of the gastric contents. The peptic activity of the stomach fluid rises parallel with the increased neutral chloride. J. F. LYMAN

**The supposed relation between surface area and hemoglobin content in the red cells of mammalia.** ERIC PONDER. *J. Physiol.* 66, 379-86(1928).—The number of red cells per cu. mm. of blood cannot be calcd. from the red-cell diam. by means of

Emmons formula:  $N = 4.56967 \times 10^3/D (D + 3.6)$ . The total area of the red cells per cu. mm. blood showed remarkably poor correlation with hemoglobin content.

J. F. LYMAN

**The respiratory quotient after evisceration in cats.** L. G. KILBORN. *J. Physiol.* 66, 403-15(1928).—After evisceration in fasting cats the respiratory quotient rose from the fasting level (0.71 to 0.8) to unity or over, indicating a change in metabolism from fat to carbohydrate. The results show, however, that after evisceration, reduction in  $O_2$  absorption was relatively greater than that of  $CO_2$  elimination and that there was a simultaneous decrease in the  $CO_2$  content and capacity of the blood. Conclusion. The high respiratory quotient obtained in decapitated, eviscerated cats is an artificial phenomenon and is not a trustworthy guide to the type of metabolism proceeding in the tissues.

J. F. LYMAN

**A non-specific pressor principle derived from a variety of tissues.** J. B. COLLIP. *J. Physiol.* 66, 416-30(1928).—A pressor substance, sol. in  $H_2O$  and in acetone, was prep'd. from a wide variety of tissues. It did not affect blood sugar; its response was augmented by small doses of ergotamine; atropine did not affect its action; nicotine did not diminish its pressor effect; small amts. had little or no effect upon isolated intestine, uterus or heart; large doses were depressant. The pressor response was directly related to size of dose within certain limits and repeated injections at short intervals did not alter the character of the response.

J. F. LYMAN

**The effect of muscular exercise on the oxygen capacity of the blood in man.** T. R. HARRISON, C. S. ROBINSON AND G. SYLLABA. *J. Physiol.* 67, 62-5(1929).—Blood from the hand veins after immersion in water at  $45^\circ$  was the same in  $O_2$  content as arterial blood while the subject breathed air. It has a slightly lower  $O_2$  content than arterial blood when the inspired gas contained 10 to 15%  $O_2$ .  $O_2$  capacity of the blood was increased during exercise. The  $O_2$  satn. of the arterial blood sometimes increased and sometimes decreased during exercise, but more often it increased.

J. F. L.

**The hydrogen-ion concentration of the isolated uterus.** PHYLLIS T. KERRIDGE AND F. R. WINTON. *J. Physiol.* 67, 66-76(1929).—The  $p_H$  of minced uterus was very little affected by that of the soln. in which it was immersed; therefore, the effect of  $p_H$  of a soln. on the tone of a uterus cannot be attributed to the sign or magnitude of the difference of  $p_H$  between the muscle and the soln. The effect of  $p_H$  on Ca ions in a soln. is discussed. There was no evidence of acid formation associated with uterine contraction.

J. F. LYMAN

**Pneumin.** A respiratory autacid from the adrenal cortex discharged into the circulation via the lymphatics. SWALE VINCENT AND J. H. THOMPSON. *Proc. Physiol. Soc., J. Physiol.* 67, iii(1929).—Something is discharged from the adrenals by way of the lymphatics which is essential to normal respiration in decerebrate cats. It is probably formed in the cortex. The name *pneumin* is suggested.

J. F. LYMAN

**Hydrogen in the tissues.** J. A. CAMPBELL. *Proc. Physiol. Soc., J. Physiol.* 67, vi(1929).—In rabbits the tension of H in the peritoneal cavity varied from 2.9 to 13.8, in cats from 1.9 to 8.9 and in monkeys from 2.9 to 20.7 mm. Hg. After a few days' starvation H completely disappeared from the peritoneal cavity. It probably is produced in the intestine as a result of fermentation.

J. F. LYMAN

**Saponin hemolysis of normal human blood with some observations on anemia blood.** H. D. KESTEN AND T. F. ZUCKER. *Am. J. Physiol.* 87, 274-9(1928).—The rate of saponin hemolysis of different normal human blood samples was essentially the same under the same conditions of temp., red-cell concn. and saponin concn. Hemolysis was inversely proportional to the cell concn. and directly proportional, through the greater portion of the reaction, to the square of the saponin concn. Blood from persons with severe secondary anemia showed a somewhat lower rate of saponin hemolysis than did normal blood.

J. F. LYMAN

**Saponin hemolysis of reticulocyte-containing blood.** T. F. ZUCKER AND H. D. KESTEN. *Am. J. Physiol.* 87, 280-7(1928).—Severe secondary anemias were produced in rabbits by the withdrawal of blood, thus reducing the red-cell count 50% or more and increasing the reticulocyte percentage up to around 20%. Comparison of the rates of saponin hemolysis of normal and reticulocyte-contg. bloods shows that reticulocytes hemolyze at a lower rate than do the normal cells.

J. F. LYMAN

**Physical development and the excretion of creatine and creatinine by women.** PAULINE HODGSON AND HOWARD B. LEWIS. *Am. J. Physiol.* 87, 288-92(1928).—In 14 athletic college women the ratio between mg. of urinary creatine N excreted in 24 hrs. and body wt. in kg. was 8.5 (av.), which is of the same order of magnitude as for men. Urinary creatinine seems to be independent of sexual variations and is an index of the proportion of muscular tissue to body wt. The frequency of creatine excretion

in these subjects was similar to that usually observed in women, but there was no definite relationship of creatinuria to menstruation.

**The development of secondary sex characters in capons by injections of bull testes.** L. C. MCGEE, MARY JUHN AND L. V. DOMM. *Am. J. Physiol.* 87, 406-35(1928).—Exts. contg. the lipoids of bull testes, injected into capons, stimulated the growth of the comb, wattles and ear lobes. The most active prepn. was obtained by: (1) Extn of the fresh ground tissue with twice its wt. of 95% EtOH, evaporation of the ext. to a sludge; (2) extn. of the sludge with benzene; (3) concn. of the benzene ext. to 0.1 its original vol. and the addn. of 7.5 vols. of acetone and filtering after 24 hrs.; (4) concn. of the acetone ext. to a sirup under reduced pressure, absorption of the sirup on strips of filter paper and extn. with liquid NH<sub>3</sub>. From 168 g. of benzene-sol. solids, 6.7 g. of NH<sub>3</sub>-sol. active lipoids were obtained.

**The effects of injecting lipid extracts of bull testes into castrated guinea pigs.** CARL R. MOORE AND L. C. MCGEE. *Am. J. Physiol.* 87, 436-46(1928).—A lipid fraction of bull testes, sol. in dil. alc., in benzene and in acetone, injected into castrated guinea pigs prolonged the survival time of the spermatozoa remaining in the epididymides of the operated and treated animals as did the hormones produced by the intact living testicle.

**Distribution of testicular growth-stimulating principle in tissues.** T. F. GALLACHER. *Am. J. Physiol.* 87, 447-9(1928).—The active principle of testicular tissue which stimulates the comb growth in capons was not obtained from any other bull tissue except epididymis.

**The physiology of the liver. XVI. The respiratory quotient and basal metabolic rate following removal of the liver and injection of glucose.** F. C. MANN AND W. M. BOOTHBY. *Am. J. Physiol.* 87, 486-96(1928).—Gaseous metabolism in trained dogs before and after the removal of the liver and before and after the injection of glucose showed that (1) the total heat production was not changed by the total loss of the liver, (2) the respiratory quotient increased immediately after the removal of the liver; and (3) glucose had a greater specific dynamic action in the dehepatized animal than in the normal one. **XVII. The effect of removal of the liver on the specific dynamic action of amino acids administered intravenously.** C. M. WILHELMJ, J. L. BOLLMAN AND F. C. MANN. *Ibid* 497-509.—The intravenous injection of alanine and glycocoll into dogs whose livers had been removed failed to produce elevation in the O<sub>2</sub> consumption but did produce elevation of the respiratory quotient. Conclusion: The specific dynamic action of amino acids is not the result of direct stimulation brought about by the presence of amino acids in the tissues.

**The carbon dioxide capacity of the human body and the progression effects of carbon dioxide upon the breathing.** E. F. ADOLPH, F. D. NANCE AND M. S. SHILING. *Am J Physiol.* 87, 532-41(1928).—When the human body was satd. at a new level of CO<sub>2</sub> tension, from 82 to 97% of the CO<sub>2</sub> was absorbed by the tissues and from 3 to 18% by the blood. When air contg. 4.5% CO<sub>2</sub> was rebreathed for 30 min. no steady state was reached; but ventilation, alveolar tension, respiratory quotient and dead space varied. At the close of the CO<sub>2</sub> rebreathing 30 min. or more was required for the normal respiratory equilibrium to return.

**The alleged presence of carotin in pig liver.** L. S. PALMER. *Am. J. Physiol.* 87, 553-7(1929).—Pig liver does not contain carotin, but it does contain a small amt. of a pigment resembling carotin in soly. and adsorption properties which gives some color reactions similar to those given by the carotinoids, but which fails to give others. The spectroscopic properties of the liver pigments are totally unlike those of carotin.

**The glycogenic function of skeletal muscle in the dehepatized dog, with special reference to the role of insulin therein.** J. MARKOWITZ, F. C. MANN AND J. L. BOLLMAN. *Am. J. Physiol.* 87, 566-83(1929).—Muscle glycogen was deposited when a dog, whose liver had been removed, was given intravenously at least 1 g. of glucose for each kg. of body wt. each hr. The presence of the pancreas is necessary for this effect for in its absence the giving of glucose is not followed by deposit of muscle glycogen unless large amts. of insulin were given.

**Human physiology. I. The metabolism and body temperature (oral) under basal conditions.** F. R. GRIFFITH, JR., G. W. PUCHER, KATHERINE A. BROWNELL, JENNIE D. KLEIN AND MABLE E. CRAMER. *Am. J. Physiol.* 87, 602-32(1929).—There was no significant correlation between the intra-individual variations of temp. and metabolism, wt. and metabolism or protein and total metabolism. There was the usual inter-individual correlation between wt. and metabolism and a negative correlation between the inter-individual correlation between wt. and metabolism and a negative

correlation between the inter-individual values for temp. and metabolic rate. Sleep or vacations did not affect the metabolism appreciably. The basal oral temp. probably undergoes a seasonal variation with its lowest value in the spring. Neither the protein or non-protein metabolism nor the  $\text{CO}_2$  excretion showed concurrent seasonal variations with the different subjects. J. F. LYMAN

Effect of corpus luteum and ovarian extracts on the estrus of the guinea pig. D. I. MACHT, A. E. STICKELS AND D. L. SECKINGER. *Am. J. Physiol.* 88, 65-76(1929).— $\text{H}_2\text{O}$  exts. of corpus luteum injected into guinea pigs inhibited estrus. J. F. L.

The secretion of uric acid by the fowl. O. S. GIBBS. *Am. J. Physiol.* 88, 87-100 (1929); cf. *C. A.* 23, 3022.—When a tube was placed in a fowl's ureter so that secretion pressure would be balanced by a column of liquid in the tube, equil. was reached at between 10 and 20 cm.  $\text{H}_2\text{O}$  pressure in most cases, max. = 42 cm. Back pressures in the ureters interfered with or stopped uric acid excretion by the kidneys, the uric acid content of the blood rising meantime. It is believed that  $\text{H}_2\text{O}$  and uric acid are excreted independently by the kidney,  $\text{H}_2\text{O}$  probably by filtration and uric acid by active secretion. J. F. LYMAN

The effect of massaging the thyroid on the basal metabolic rate of dogs. C. S. SMITH AND O. B. DE COUTO-E-SILVA. *Am. J. Physiol.* 88, 183-6(1929).—No effect on basal metabolism in dogs was noted after vigorous massage of the thyroid glands. J. F. LYMAN

The influence of suprarenal cortex and medulla on the growth and maturity of young (white leghorn) chicks. A. G. EATON, W. M. INSKO, G. P. THOMPSON AND F. E. CHIDESTER. *Am. J. Physiol.* 88, 187-90(1929).—Chicks fed desiccated suprarenal medulla grew almost the same as the controls for the first 3 weeks; after this their growth was less rapid than that of the controls. Dried suprarenal cortex produced a decrease in the rate of growth, but after 8 weeks' feeding growth was more rapid than in the controls. The testes of the cortex-fed males were larger and those of the medulla fed males were smaller than those of the controls. J. F. LYMAN

The influence of desiccated suprarenal cortex and medulla on the growth and maturity of white rats. F. E. CHIDESTER, A. G. EATON AND G. P. THOMPSON. *Am. J. Physiol.* 88, 191-4(1929).—The growth of young white rats was retarded when they were fed 0.5 g. dried suprarenal cortex or medulla daily, especially at first by cortex. Young female rats fed dried cortex reached sexual maturity sooner than controls or those fed dried medulla. J. F. LYMAN

The effect of ergotamine on the blood sugar level. L. B. SHPINER. *Am. J. Physiol.* 88, 245-50(1929).—Ergotamine injected into dogs prevented the development of adrenalectomy hyperglucemia and glucosuria; it lowered the blood sugar and stopped glucosuria in dogs whose pancreas glands had been partially removed and that had been fed thyroid; but it had no effect on the hyperglucemia and glucosuria in dogs made diabetic by total removal of the pancreas. J. F. LYMAN

The effect of prolonged general anesthesia and of decerebration on the lactic acid and glycogen contents of mammalian skeletal muscle. J. C. HINSEY AND H. A. DAVENPORT. *Am. J. Physiol.* 88, 286-94(1929).—The lactic acid content of the blood and tonic muscles of decerebrate cats was higher than that of resting normal animals, while the muscle glycogen content of the tonic and atonic muscles was essentially the same. Under ether anesthesia the muscle lactic acid content was initially high but tended to drop as anesthesia progressed. Under amylal anesthesia the glycogen content of rat and guinea pig muscle did not decrease during 3.5 hrs. J. F. L.

The regulation of respiration. XXV. Variations in the lactic acid metabolism in the intact brain. D. A. MCGINTY. *Am. J. Physiol.* 88, 312-25(1929).—A comparison of the lactic acid content of blood supplying the brain with that returning from it showed that with normal oxidations in the brain tissue lactic acid was absorbed from the arterial blood and utilized by the brain cells. With impaired oxidations, induced by NaCN or by partial or complete occlusion of the cerebral blood supply an excessive production of lactic acid in the brain cells with an outward diffusion into the blood stream occurred. XXVI. Total carbon dioxide content of the brain as affected by hemorrhage and the injection of sodium cyanide. E. E. KLEINSCHMIDT. *Ibid* 251-8.—A method is described for prep. brain tissue for  $\text{CO}_2$  analysis. Conditions of lowered oxidation in the brain, produced by hemorrhage or by NaCN injection, resulted in a falling off of  $\text{CO}_2$  within the brain. The buffering capacity of the normal brain is less than that of the normal blood and both are decreased with impaired oxidation. The data are in accord with the view that the  $p_{\text{H}}$  of the center is an important factor in the control of respiration. XXVII. The effect upon salivary secretion of varying the carbon dioxide and oxygen contents of the inspired air. NATHAN B. EDDY. *Ibid*

534-45.—The submaxillary gland of the dog, secreting at const. rate under the influence of pilocarpine, was stimulated to increased secretion by increasing the  $\text{CO}_2$  of the inspired air. Decreasing the  $\text{O}_2$  of the inspired air decreased the rate of secretion. Both procedures increased the vol. flow of blood through the gland. **XXVIII. Lymph acidity and lymph flow during administration of sodium bicarbonate and carbon dioxide.** ROBERT GESELL. *Ibid* 546-53.—The intravenous injection of  $\text{NaHCO}_3$  into dogs decreased the H-ion concn. of blood and thoracic lymph equally. The administration of  $\text{CO}_2$  by the inspired air increased the acidity of blood and lymph. The capillaries of the liver and gastrointestinal tract seem to be highly permeable to  $\text{NaHCO}_3$  and to  $\text{CO}_2$ . **XXIX. Lymph acidity and lymph flow during impaired oxidations produced by cyanide.** ROBERT GESELL. *Ibid* 554-61.—The effects of  $\text{NaCN}$  on the  $\text{pH}$  of the lymph were different when the animal was allowed to control its ventilation and when ventilation was artificially maintained at const. vol. The early effects, in general, were decreased hydrogen-ion concn. during normal ventilation and increased H-ion concn. during const. ventilation. This agrees with the findings of Gesell and Hertzman on the cerebrospinal fluid. Cf. *C. A.* 23, 3963. J. F. LYMAN

**Physiology of the corpus luteum. II. Production of a special uterine reaction (progestational proliferation) by extracts of the corpus luteum.** G. W. CORNER AND W. M. ALLEN. *Am. J. Physiol.* 88, 326-39(1929).—An ext. of corpus luteum was prepd. by (1) extn. with hot alc. and evapn. of the alc. and (2) pptn. and removal of the phospholipins from an ethereal soln. of the alc.-sol. lipins by the addn. of acetone. Such exts., freed of phospholipins, when injected into castrated adult female rabbits induced a characteristic alteration of the endometrium identical with the progestational proliferation known to be due to the presence of corpora lutea in the ovaries. Conclusion: The exts. of corpora lutea used contained a special hormone which has for one of its functions the prepn. of the uterus for reception of the embryo. Estrin or exts. of human placenta did not produce progestational proliferation of the uterus. **III. Normal growth and implantation of embryos after very early ablation of the ovaries, under the influence of extracts of the corpus luteum.** W. M. ALLEN AND G. W. CORNER. *Ibid* 340-6.—Female rabbits whose ovaries were removed by operation at the 18th hr of pregnancy and treated subsequently with alc. ext. of corpus luteum showed normal implantation and growth of the embryos. Conclusion: In the rabbit the corpus luteum is an organ of internal secretion which has for one of its functions the production of a special state of the uterine mucosa which makes possible the nourishment and protection of the free blastocytes and their implantation on the uterine wall. J. F. LYMAN

**The optimal water requirement in renal function. I. Measurements of water drinking by rats according to increments of urea and of several salts in the food.** J. L. GAMBLE, M. C. PUTNAM AND C. F. MCKHANN. *Am. J. Physiol.* 88, 571-80(1929). When 2 millimols. or more of  $\text{NaCl}$ ,  $\text{KCl}$ ,  $\text{KHCO}_3$  or urea per g. of food was added to the diet of rats an approx. stationary concn. in terms of water intake was established. The values for  $\text{NaCl}$  were 0.63  $M$  and for urea 1.01  $M$ . The optimal water requirement for each of the salts was identical, or nearly so, and for salt mixts the water requirement was additive or nearly so. For mixts. of salts and urea the water requirement was not additive, but the same as for an equiv. amt. of urea alone. J. F. L.

**The metabolism of muscle. II. The respiratory quotient of exercising muscle.** H. E. HIMWICH AND M. I. ROSE. *Am. J. Physiol.* 88, 663-79(1929); cf. *C. A.* 23, 3445.—Respiratory quotients for (1) non-isolated muscles, (2) isolated muscles and (3) for the animal as a whole were detd. on dogs. The respiratory quotient obtained from the blood of exercising muscle usually agrees with that obtained for the resting animal as a whole. There is thus no evidence pointing to exclusive carbohydrate utilization during exercise; rather the working muscles seem to oxidize foodstuffs in the same proportion as the whole organism during rest. J. F. LYMAN

**The respiratory quotient of testicle.** H. E. HIMWICH AND L. H. NAHUM. *Am. J. Physiol.* 88, 680-5(1929).—The respiratory quotients of the testicle indicate that this organ oxidizes the usual combination of foodstuffs. J. F. LYMAN

**The carbon dioxide absorption curve and buffer value of the blood in physical hyperthermia.** M. GARCIA BANUS WITH J. M. WILCOX. *Am. J. Physiol.* 88, 709-23(1929).—In anesthetized dogs whose temp. was raised and maintained at  $40^\circ$  and  $41^\circ$  for 8 hrs. or longer there was an increase in the total solids of the blood, a decrease in  $\text{O}_2$  capacity and an increase in labile, loosely bound base. The hemoglobin which disappeared from the blood as  $\text{O}_2$  capacity may have been transformed into a substance with a smaller acid dissocn. const. J. F. LYMAN

**The inversion effect on blood pressure of preparations from the posterior lobe of the pituitary gland.** R. L. STANLEY. *Am. J. Physiol.* **88**, 724-8(1929).—The posterior lobes of cattle were preserved in acetone. After draining off the acetone the glands were ground and heated with water to boiling and the insol. material sepd. by centrifuging. Washings from the insol. material were combined with the first soln. and the combined solns. clarified by the addition of colloidal iron and filtration. The filtrate was evapd. under reduced pressure at 50° to small vol. and absolute alc. added to complete pptn. The ppt. was sepd. by centrifuging and the alc. soln. discarded. The alc.-insol. material was washed with absolute alc. and dried in a vacuum desiccator. Preps. as described above showed no reversal of action on blood pressure upon repeated injections at 10-min. intervals. J. F. LYMAN

**The blood plasma calcium of normal and parathyroidectomized albino rats.** W. R. TWEDDY AND S. B. CHANDLER. *Am. J. Physiol.* **88**, 754-60(1929).—Removal of both parathyroid glands in rats was followed by a rapid drop in blood plasma Ca (9.25 to 12.5 mg. Ca per 100-cc. plasma in normal rats to 5 to 8 mg. in operated rats). Parathyroidectomized rats were 2 to 3 times more reactive to parathyroid hormone injections than were normal rats. J. F. LYMAN

**Studies on the labile phosphorus of the blood.** G. DE TONI. *Boll. soc. ital. biol. sper.* **4**, 161-5(1929).—The effect of time and temp. on the labile P in sterile citrated blood was studied. The amt. of inorg. P in the blood kept at 1-2° for 24 hrs. remained unchanged. There was an increase of 10-40% in blood kept at 16-18° for 24 hrs. There was an enormous increase in inorg. P in blood kept at 37° for 24 hrs.; the amt. of P was in some cases 8 times the original titer. Such variations are less pronounced in plasma and still less are the variations in the  $\text{CCl}_3\text{CO}_2\text{H}$  blood filtrates kept under similar conditions. In a second series of expts. the temp. was kept const. (16-18°) and the time was varied. The results showed that in  $\text{CCl}_3\text{CO}_2\text{H}$  filtrates there is a decided tendency for the inorg. P to increase gradually. PETER MASUCCI

**The intestinal elimination of iron studied in animals by means of vital stains.** P. MASCHERPA. *Boll. soc. ital. biol. sper.* **4**, 178-81(1929).—During the elimination of Fe, the intestine takes the vital stain more intensely. The mobile cells which transport Fe from the blood vessels to the secretory epithelia of the intestine are not leucocytes but are cells belonging to the reticulo-endothelial system. PETER MASUCCI

**The limits of the action of the hydrogen-ion concentration on the blood vessel tone.** G. RUSSO. *Boll. soc. ital. biol. sper.* **4**, 206-8(1929).—By means of perfusion methods with the Trendelenburg-Läwen frog prepn., R. obtained the following results: (1) The vessels are sensitive to a variation of 0.2  $p_H$  from the normal  $p_H$  7.4;  $p_H$  7.2 cause vasodilation and  $p_H$  7.6 vasoconstriction. (2) An indifferent zone exists,  $p_H$  5.6-6.6, in which the vessels are not sensitive to changes in  $p_H$ ;  $p_H$  6.6 is the max. point of vasodilation. (3) The changes in  $p_H$  which provoke the sharpest vasomotor reactions are those close to the normal  $p_H$  of biol. fluids. PETER MASUCCI

**Studies on oxidases. V. Recent studies on the oxidases of spermatozoa.** E. SERENI. *Boll. soc. ital. biol. sper.* **4**, 230-8(1929).—Exptl. data are given tending to support the importance of the epididymis as the organ in which the physiological maturation of the sperm is accomplished. In the epididymis and probably through the action of its secretion, the spermatozoa become more mobile, and the duration of their mobility outside the organism lasts longer; their resistance to heat is increased. Paralleling these modifications, the spermatozoa acquire a marked power to oxidize the  $\alpha$ -naphthol-dimethyl- $p$ -phenylenediamine reagent. As long as the spermatozoa are devoid of mobility, they are also free from oxidase granules; these appear, however, when the spermatozoa become mobile. PETER MASUCCI

**Hydroxyl ions and the spinal medulla.** MICHELE MITOLO. *Boll. soc. ital. biol. sper.* **4**, 259-62(1929).—The application of alkalis on the dorsal surface of the spinal medulla of the frog (Baglioni's prepn.) causes tetanic convulsions and strychnine-like tetany. The OH ions act on the sensor-coördinator elements. If the alkalis are applied on the ventral surface, then they induce clonic convulsions of the phenolic type. The OH ions act on the motor centers of the spinal medulla. PETER MASUCCI

**The acid-alkali equilibrium and kidney function.** L. DAMAS. *Bull. sci. pharmacol.* **36**, 303-9(1929).—A general discussion. A. E. MEYER

**Physical chemistry of body fat. A contribution to the problem of the physiology of fattening.** WALTER SPRANGER. *Biochem. Z.* **208**, 164-78(1929).—The viscosity of Ringer soln. is not noticeably altered by the addn. of Na oleate, Ca oleate, lecithin, cholesterol or cholesterol esters in physiological concns. In the absence of neutral fat no antagonism is observed between these substances. Albumin, lecithin and Na oleate in a physiological model act as oil/water emulsifying agents. An increased

addn. of cholesterol or lecithin causes not a greater dispersion of the fat but a sepn. of the phases that manifests itself in a fall of viscosity. Cholesterol esters are even more strikingly effective in this respect than the cholesterol. By reducing the  $H_2O$  + protein + lecithin phase and increasing the fat quantity, cholesterol ester produces sepn. and actual reversal of phase from the oil/water to the water/oil. The optimum condition for the oil/water emulsion exists when of the total cholesterol only about 60% is in the form of esters and the rest is free, and a shift in proportion in either direction leads to sepn. and reversal of phases. In the body fat depots the emulsion behaves like a water-in-oil emulsion.

S. MORGULIS

**Lactic acid excretion in urine and sweat in different sports.** I. SNAPPER AND A. GRÜNBAUM. *Biochem. Z.* **208**, 212-20(1929); cf. *C. A.* **23**, 3500.—Football players, during a double game of 45 min. each, on a warm day excrete lactic acid in the urine, 11% of the players eliminating over 60 mg. On cold days 50% of the players excrete over 60 mg. lactic acid; on warm days 468 mg. lactic acid and 846 mg. Cl were recovered from their shirts. This leads to the supposition that the total elimination by way of the sweat was 1-2 g. lactic acid. 28 out of 39 participants in bicycle races (6-8 min. for a 2-km. course) had more than 60 mg. lactic acid in the urine; in a very difficult race over a similar distance 24 out of 27 bicyclists had more than 60 mg. lactic acid in the urine (max. 1.425 g.). Their shirts yielded an av. of 97.5 mg. lactic acid and 84 mg. Cl. Fast runners (time 9 min. to 2.5 hrs. over distances of 3, 5, 10 or 12 km.) have as a rule little lactic acid in the urine, so that when the exertion lasted more than 9 min. a "steady state" was evidently established during running. Swimmers whether over 400 m (5 min.) or 1500 m. (20-22 min.) and waterball players (twice 7½ min.) all excrete much lactic acid in the urine (max. 1.76 g.), so that in swimming even after 15 min. the "steady state" has not been established. Albuminuria occurs very seldom among trained football players, bicyclists or runners, but is frequent among swimmers. Glucosuria was observed only in one football and in one waterball player.

S. MORGULIS

**The decomposition of creatine phosphoric acid in relation to the activity of the muscles.** II. D. NACHMANSOHN. *Biochem. Z.* **208**, 237-56(1929); cf. *C. A.* **23**, 877.—The relation between the decompn. of creatine-phosphoric acid and the tension developed by a muscle has been quant. studied under different conditions. For this purpose the isometric coeff.  $K_m$  (kg. tension  $\times$  cm. muscle length/mg.  $H_3PO_4$  set free) as well as the isometric times coeff.  $K_z$  (kg. tension  $\times$  cm. muscle length  $\times$  seconds/mg.  $H_3PO_4$ ) were detd. The av. value for  $K_z$  for 2-second tetanus is 15, for 5 sec. 32, for 10 sec 50. The anaerobic resynthesis for tetanus of various durations is more or less proportional to the amt. decomposed, namely about 30%. In curarized muscles, on the contrary, the  $K_z$  value even for a 2-second tetanus is relatively large and does not vary with further prolongation of the tetanus. When muscles are placed in Ringer soln. contg. P, creatine-phosphoric acid synthesis occurs beyond the normal content of muscle, so that about 95% of the creatine becomes esterified. In the isometric contractions much less phosphagen is decomposed at high than at low temp., although the developed tension and the lactic acid production under these conditions are the same. The  $K_m$  value for 30 to 50 single contractions is 70-100 at 4° and 40-60 at 24°.

S. MORGULIS

**The citric acid content of normal human urine.** OTTO ÖSTBERG. *Biochem. Z.* **208**, 352-3(1929).—Normal human urine contains an av. of 0.025-0.18% citric acid.

S. MORGULIS

**The respiratory quotient of nerves during rest and activity.** OTTO MEYERHOFF AND F. O. SCHMITT. *Biochem. Z.* **208**, 445-55(1929).—The av. value of the resting respiratory quotient of frog nerve was 0.77, but in the four best expts. the av. was only 0.69. During activity the av. respiratory quotient was 0.87 (variations 0.71 to 1.03).

S. MORGULIS

**The asymmetric utilization of *p*-sec.-butylphenol in the animal organism.** CLAUDE FROMAGNOT. *Biochem. Z.* **208**, 490-2(1929).—When synthetic, optically inactive *p*-sec-butylphenol is fed to animals, the urine always yields *l*-sec-butylphenol, showing that the dextro component must have been utilized by the organism.

S. MORGULIS

**The effect of lecithin and cephalin on the working capacity of the surviving frog muscle.** NILS NIELSEN. *Skand. Arch. Physiol.* **56**, 216-24(1929).—Pure lecithin and cephalin have been prepd. from brain tissue by the method of Levene and Rolf. No effect was observed on the frog heart when the Göthlin perfusion fluid was exchanged for one contg. lecithin or cephalin. Other expts. were made on the frog gastrocnemius perfused either with Göthlin's soln. + glucose, or with the same soln. contg. emulsified phosphatide, or with serum, the work consisting of 300 contractions with a 20-g. wt. Changing over from Göthlin's soln. to serum increased the working capacity. Chang-

ing over from Göthlin's soln. to the same contg. a 0.01–0.1% emulsion of lecithin in no instance affected the working capacity of the muscle, but a slight increase was observed in a 0.01% emulsion of cephalin.

S. MORGULIS

**Influence of room temperature upon the quantity of oxygen consumption in an intestinal canal and the relation between the oxygen consumption and the intestinal motion.** RYOSUI SAMEISHIMA. *Hokkaido J. Med.* 6, 893–913(1928).—The O consumption of the rabbit intestine increases with the rise of temp. in the temp. range of 18–41°, the sugar absorption being also larger at higher temp. The temp. coeff. of the former action is 2.2–2.7, while that of the latter action is 1.7. The O consumption suffers no change even when the absorptive power of the intestine is destroyed by  $\text{HgCl}_2$ , from which fact S. concludes that the oxygen consumption of the intestine is chiefly due to its motion and has little relation to the absorbing action. K. S.

**Neutralization of acids and alkalies in the intestinal canal.** RYOJUN KINOSHITA, SEIKEN SUKAI AND HIROSHI NAKAMURA. *J. Exptl. Digestive Diseases* 3, 723–35(1928).—The intestinal canal of a rabbit was washed, physioli. NaCl soln. was poured into it, and the reaction of the soln. was measured after 45 min. The change of the reaction was also examd. after 1 hr. by adding 0.1 N acid or 0.01 N alkali. Evidence was found that in the intestine the reaction is regulated by the blood, the intestinal juice and the mucous membrane. K. SOMEYA

**Influence of temperature upon the acetaldehyde production.** CHOJI KAWAMURA. *J. Kyoto Prefectural Med. Coll.* 2, 211–22(1928). (In German).—K. added to rabbit blood or to pulped organs  $\text{CaSO}_4$  and a phosphate buffer ( $p_H$  6.5) and allowed the mixt to stand for 5 hrs. at 30°, 34° and 38°, and then measured the  $\text{MeCHO}$  content by a modified method of Neubury, Ripper, etc. In the liver, blood and muscle,  $\text{MeCHO}$  production was max. at 38°. The amt. produced in the liver was 2.4 mg. %, in muscle 1.13 mg. % and in blood 1.08 mg. %.

K. SOMEYA

**The appearance of glycogen in the mucous membrane of the alimentary canal.** XVI-XVII. KYUHAN YOSHIDA. *J. Study of Microorganisms* 22, 2385–402, 2403–24 (1928).—Subcutaneous or intravenous injection of starch, insulin or glycogen into a rabbit seldom caused formation of glycogen in the alimentary mucous membrane. The liver glycogen was only slightly increased by the injection of glycogen. The appearance of glycogen is attributed to a polymerizing action of the superficial intestinal cells on the excessive accumulation of blood sugar. On NaCl injection the increase of the blood sugar is small and there appears no glycogen in the mucous membrane. K. SOMEYA

**Change of hydrogen-ion concentration in the urine at low atmospheric pressure.** SEICHOKU MATSUKA. *Naval J. Med.* 17, 261–3(1928).—Two healthy men were put into a low-pressure chamber, and the pressure was gradually decreased up to the pressure prevailing at the height of 5000 m. The alkali excretion in the urine was increased. With const. low O pressure, the amt. of alkali excreted increases with the time. The total urine increases at atm. pressures equiv. to heights above 3000 m.

K. SOMEYA

**Distribution and variation of glycogen in the intestinal mucous membrane of the mammal embryo.** ICHIRO MARUYAMA. *Okayama J. Med.* 40, 1296–333(1928).—In the intestinal canal of the 20-day-old rabbit embryo there is 0.79% glycogen, while in the 30-day-old rabbit there is 0.53%. In a marmot embryo weighing 8.71 g. and 5.24 cm. long 0.677% of glycogen was found, while in another weighing 62.07 g. and 12.5 cm. long, there was found 3.223% of glycogen. In the intestinal mucous membrane of a dog embryo measuring 5.98 cm. in length, there was found 0.839% glycogen, while in another measuring 15.42 cm. in length, 0.066% of glycogen was found. The quantity of the free  $\text{H}_3\text{PO}_4$  in the intestinal mucous membrane of the rabbit or of the dog increases with lapse of time after conception both in its absolute amount and the percentage, while in marmots the absolute amt. increases but the percentage decreases. The quantity of the lactacidogen phosphoric acid increases in its abs. amt. in the first two animals but the percentage decreases while in marmots both increase. The quantity of the inorg. constituents and the free  $\text{H}_3\text{PO}_4$  in the rabbit embryo increases with the lapse of time after conception, while the lactacidogen phosphoric acid decreases, the contrary being the case in marmots. The intestinal mucous membrane of marmots contains a considerable quantity of an insulin-like substance, while that of a dog contains only a small quantity of the same substance. K. SOMEYA

**Testicles and the water metabolism.** TARO YAMAMOTO. *Okayama J. Med.* 40, 1467–80(1928).—In a week after removal of both testicles there is a slight change of  $\text{H}_2\text{O}$  and NaCl metabolism; this change increases up to 3 weeks. Injection of spermatin into the animal appears to restore the metabolic function to a small extent. K. S.

**Glycogen I.** The glycogen deposition in the pelvis of the kidney, ureter and bladder epithelium. SADAJI HARADA. *Sei-i-kwai Med. J.* 48, No. 1, 46-83, Abstract sect. 4-5 (1929).—The glycogen in the kidney, pelvis of the kidney, ureter and bladder epithelium is not a simple deposit of the substance but is formed in the cells themselves from blood and urine sugar and serves as a reserve substance.

**Glycogen in the central nervous system of some mammals. III. Effects of inanition upon the glycogen content.** HYOSAKU TANAKA. *Sei-i-kwai Med. J.* 48, No. 2, 51-81, Abstract sect. 4-5(1929); cf. *C. A.* 23, 3257.—Guinea pigs and rabbits were starved 24 and 72 hrs. A detailed comparative examn. of sections stained by Best's carmine method was made. The glycogen content of the cerebral cortex, glia of the spinal cord and ganglion cells in the posterior end of the spinal cord decreased somewhat in the guinea pigs starved for 72 hrs. but was only slightly affected in the rabbit starved for 72 hrs. A marked decrease in the glycogen content of the liver was produced by starvation for 72 hrs. The extracellular glycogen was more markedly influenced by starvation than the intracellular.

A comparison of blood calcium levels between and during menstrual periods. EDWARD ALLEN AND H. C. GOLDTHORPE. *Am. J. Obstet. and Gynecol.* 17, 789-94 (1929).—Normal Ca values in healthy women range from 9.3 to 13.6 mg. per 100 cc plasma. The differences seem to be due to seasonal or climatic changes and variations in the concn. of the blood. No appreciable or constant effect of the normal menstrual period on the Ca content of the blood was detd.

Some factors which influence the reaction of the urine. ARMAS and IMARI VARTIAINEN. *Duodecim.* 44, 497-507(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 48, 231.—NaHCO<sub>3</sub> taken into the fasting stomach soon releases a strong alk. urinary reaction which passes rapidly. At meal time the reaction produced is weaker but more prolonged. Fruit salts taken while fasting at first produce an acid urinary reaction which later changes into an alk. one. The original acid reaction is attributed to the Na tartrate in the fruit salts. The latter taken at meal time produce an enduring and somewhat moderate action, the urine remaining alk. even on the following day.

Chemical studies of the menstrual blood. ANDOR RONA AND OLGA WALDBAUM. *Zentr. Gynäkol.* 52, 997-1005(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 644-5. Total protein and plasma protein showed no essential changes. Residual N showed an increase in 23 of 33 cases, on the first day in 88% of the cases averaging 38.19%, and on the second day in 50% of the cases averaging 16.83%. Increase of amino acids in 16 of 20 cases averaged 25%. There is also a protein decompn. which must come from the uterine mucous membrane.

The influence of insulin on the glycogen formation in the macerated liver or muscle substance and in the liver during perfusion with sugar-saline solutions. KENZO OTANI. *Okayama-Igakkaï-Zasshi* 40, 727-45(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 572.—Macerated liver of the toad, *Bufo japonicus*, can form glycogen from either glucose or fructose, while resected muscle can convert only glucose. The addn. of insulin reduces the glycogen content of both muscle and liver. The presence of glucose and fructose slows the decompn. of glycogen in the resected liver; glucose has the same effect on resected muscle. When the liver is perfused with a sugar-saline soln glycogen is formed both from dextrose and levulose. Insulin accelerates this in levulose while it retards such formation in dextrose.

New paths of therapy [hormones] (HOFMAN) 17.

## G—PATHOLOGY

H. GIDEON WELLS

Post-operative blood chemical studies. KNUTE REUTERSKIÖLD AND EDMUND ANDREWS. *Proc. Soc. Exptl. Biol. Med.* 26, 17-8(1928).—The Ca-K ratio in the blood was greatly lowered in dogs following surgical operations under ether anesthesia. This was accompanied by an increased permeability of the tissues and a tissue dehydration. Return to normal usually occurred in 24 to 36 hrs.

Occurrence of cystine in sweat of cystinurics. HOWARD B. LEWIS. *Proc. Soc. Exptl. Biol. Med.* 26, 69-70(1928).—From a cystinuric, by the use of pilocarpine and heat, 100 cc. of sweat was collected in 50 min. No cystine was detected by the colorimetric method of Folin and Looney. Wollaston's test, applied to purified sweat, was also negative.

Cause of death following intravenous injection of ox and dog serum into rabbits. JACOB RABINOVITCH. *Proc. Soc. Exptl. Biol. Med.* 26, 117-9(1928).—Both ox and

dog serum when injected in lethal doses intravenously into rabbits cause death through thrombosis, which with ox serum consists of agglutinated erythrocytes and with dog serum of fibrin thrombi.

C. V. BAILEY

**A mechanism maintaining the hyperglucemia of diabetes.** H. E. HIMWICH, W. H. CHAMBERS, Y. D. KOSKOFF, L. H. NAHUM AND M. A. ADAMS. *Proc. Soc. Exptl. Biol. Med.* 26, 120-1(1928).—Fourteen completely diabetic depancreatized dogs were put under amytal anesthesia and samples of blood were synchronously drawn from the femoral artery, femoral vein, portal vein and hepatic vein. Glucose and lactic acid were detd. The results showed that the liver forms carbohydrate from the lactic acid liberated by muscle and that the glucose is not stored in the liver but passes into the blood stream and constitutes a factor in maintaining the hyperglucemia of diabetes.

C. V. BAILEY

**Hemagglutination by tumor extracts.** K. LANDSTEINER. *Proc. Soc. Exptl. Biol. Med.* 26, 134-5(1928).—Exts. of tumors of human or lower animal origin have a distinct agglutinating effect on rabbit red blood cells. This activity disappears rapidly as a result of oxidation. The deterioration is markedly delayed by addn. of cysteine 1:500 and by covering the ext. with liquid paraffin. The action is different from agglutination by serum. Saline exts. of normal organs do not show this phenomenon.

C. V. BAILEY

**Experimental edema.** LOUIS LEITER. *Proc. Soc. Exptl. Biol. Med.* 26, 173-5 (1928).—Dogs were bled twice daily; 400 to 500 cc. of blood was withdrawn and the corresponding quantity of erythrocytes, suspended in Locke's soln., was reinjected into the saphenous vein. 1500 cc. of 0.85% NaCl soln. was given daily by stomach tube. Anasarca developed about the 5th day. Edema usually appeared when the plasma proteins had fallen to 3% or less. Ascitic or subcutaneous edema fluid had a protein content of 0.25 to 0.1%. The massive edema and ascites did not impair the good general condition of the dog.

C. V. BAILEY

**Tetany and blood calcium after thyroparathyroidectomy in the goat.** E. LARSON AND LEO A. ELKOURIE. *Proc. Soc. Exptl. Biol. Med.* 26, 210-3(1928).—In the goat the usual operation for the removal of the thyroids and parathyroids does not result in tetany; under these conditions the goat can maintain a normal or nearly normal blood Ca.

C. V. BAILEY

**Use of paramacia for studying toxins and antitoxins (measles, scarlet fever and diphtheria).** RUTH TUNNICLIFF. *Proc. Soc. Exptl. Biol. Med.* 26, 213-7(1928).—Paramacia can be used to det. toxin production of certain bacteria; the method is crude as the toxins are not sufficiently potent to be dild. Paramacia may be helpful in detg. the strength of antitoxins.

C. V. BAILEY

**Precipitin production with phosphorized caseinogen.** E. E. ECKER AND M. A. SIMON. *Proc. Soc. Exptl. Biol. Med.* 26, 222-4(1928).—Both native and phosphorized caseinogen are precipitinogenic. The reactions occur in higher dilns. when the homologous proteins are employed. Antisera against either form will ppt. the other. Phosphorylation of the caseinogen does not destroy its antigenic character.

C. V. B.

**Antipneumococcus protective substances in normal pig serum.** RICHARD H. P. SIA. *Proc. Soc. Exptl. Biol. Med.* 26, 284-6(1929).—White mice weighing about 20 g. were each given intraperitoneal injections of 1 cc. of pig serum and 4 hrs. later varying amts. of an actively growing culture of a virulent Type I pneumococcus. Sera from susceptible animals, the rabbit and the guinea pig, were used as controls and these conferred no protection. Normal pig serum protected mice against 10,000 times the min. fatal dose. By absorption expts. normal pig serum was found to contain type specific protective substances for Types I and II and to a less degree for Type III.

C. V. BAILEY

**Effect of liver autolysis in vivo.** JAMES C. ELLIS AND LESTER DRAGSTEDT. *Proc. Soc. Exptl. Biol. Med.* 26, 304-5(1929).—The uncontaminated liver of normal healthy adult dogs regularly contains anaerobic spore-bearing bacteria; probably this causes death in "in vivo aseptic autolysis of the liver" expts. in which parts of the animal's own liver are placed free in the peritoneal cavity. When fetal liver or autoclaved adult liver is used, toxic symptoms do not develop.

C. V. BAILEY

**The sensitizing dose in respiratory anaphylaxis (asthma).** BRET RATNER AND HELEN L. GRUEHL. *Proc. Soc. Exptl. Biol. Med.* 26, 327-8(1929).—Guinea pigs were exposed to air laden with horse dandruff dust. Hypersensitiveness was proved by an intravenous injection of 0.3 to 0.5 cc. of horse dandruff ext. after an interval of 3 weeks. A suggestion of sensitiveness may result from an exposure lasting  $\frac{1}{4}$  hr.; definite sensitization is produced in 1 hour. Some individuals apparently cannot be sensitized at all.

C. V. BAILEY

**Transitory character of the achlorhydria during fever demonstrated by the histamine test.** HILDING BERGLUND AND H. CHIEN CHANG. *Proc. Soc. Exptl. Biol. Med.* **26**, 422-3(1929).—By substituting the histamine test for the test meal the gastric secretion was studied during severe fevers without inconvenience to the patient. The fasting stomach was emptied; 0.5 mg. of *ergamine* (Burroughs Wellcome) was injected subcutaneously and the gastric contents withdrawn for analysis at the end of the 20. min. period. Under these conditions achlorhydria was found in 23 patients with fever varying from 38.4° to 40.4°. In most cases convalescence was accompanied by a recurrence of free acid and the amt. of gastric secretion was increased. C. V. BAILEY

**Increase in guanidine-like substances in acute liver injury and eclampsia.** A. S. MINOT AND J. T. CUTLER. *Proc. Soc. Exptl. Biol. Med.* **26**, 607-11(1929).—In certain clinical types of liver disease and in eclampsia the blood showed an increase in guanidine, as detd. by the method of Major and Weber, and a decrease in sugar. Ca medication furnished prompt relief in a few clinical cases. C. V. BAILEY

**Occurrence of heat-labile toxins in closed intestinal loops.** J. T. MCCLINTOCK AND H. H. HINES. *Proc. Soc. Exptl. Biol. Med.* **26**, 654-5(1929).—An unheated Berkefeld filtrate from closed intestinal loops was more toxic for guinea pigs than fluid heated for 1 hour at 65°. C. V. BAILEY

**Is the sensitizing effect of cholesterol for antigen used in the complement-fixation test for syphilis due to the contaminating sterol, ergosterol?** ELIZABETH MALTANER. *Proc. Soc. Exptl. Biol. Med.* **26**, 677-8(1929).—The sensitizing action of cholesterol purified by the dibromide method was equal to that of the unpurified sample containing ergosterol. C. V. BAILEY

**Pancreatic function. III. The pancreatic secretion in disturbed gastric secretion.** SEIZABURO OKADA, TSUNAMOTU IMAZU, KWANICHI KURAMACHI, MASAKA MATSUBARA AND TOSHIO TSUKAHARA. *Arch. Internal Med.* **43**, 413-9(1929); cf. *C. A.* **23**, 1673. The enzymic activity of the pancreatic juice was detd. in 7 cases of achylia gastrica and in 5 cases of cancer of the stomach with achlorhydria. No evidence was obtained for disturbance of pancreatic function with disturbance of gastric secretion. In some cases increased pancreatic activity was noted. HCl is not necessary to stimulate normal pancreatic secretion. It is suggested that some other powerful stimulating mechanism than secretin exists. J. B. BROWN

**The Andrewes diazo reaction in nephritis.** J. S. EASTLAND AND E. G. SCHMIDT. *Arch. Internal Med.* **43**, 472-82(1929).—The Andrewes diazo reaction on blood serum or plasma is a simple test for advanced renal damage. It was always found to be associated with marked retention of N. J. B. BROWN

**The metabolism in pernicious anemia.** HOWARD L. ALT. *Arch. Internal Med.* **43**, 488-503(1929).—The metabolism of 5 cases of pernicious anemia was studied during treatment with liver ext. Voluntary caloric intake increased rapidly. A negative N balance became positive. A decrease in urine output later became greater than fluid intake. The basal metabolic rate was normal at first, was low during the generation of red cells and finally returned to normal. J. B. BROWN

**Cutaneous and venous blood-sugar curves. II. In benign glucosuria and in diabetes.** MYER FRIEDENSON, M. K. ROSENBAUM, F. J. THALHEIMER AND J. W. PETERS. *Arch. Internal Med.* **43**, 633-52(1929); cf. *C. A.* **23**, 874.—Arterial and venous blood-sugar curves were studied in patients with nondiabetic glucosuria and with diabetes after administration of glucose or mixed meals with and without insulin therapy. Benign glucosuria and diabetes can not be distinguished by the presence or absence of a positive arterial-venous blood sugar difference. J. B. BROWN

**Studies in fat metabolism. II. The character of blood lipides in hepatic disorders, including migraine.** C. W. McCLURE AND MILDRED E. HUNTSINGER. *Arch. Internal Med.* **43**, 715-30(1929); cf. *C. A.* **22**, 800.—The blood lipides were studied in patients with various diseases of the liver. Hyperlipemia and unusually high I numbers of the fatty acids were indications of disturbances in lipide metabolism. Changes in the character of the lipides were produced by ingestion of foodstuffs. The type of food was not important. It is suggested that the lipide changes are due to mobilization from the body tissues. The cholesterol fraction gave an unusually low I no. Ingestion of food did not affect lecithin-P concn. of the blood. J. B. BROWN

**Hyperinsulinism.** FRANK N. ALLAN. *Arch. Internal Med.* **44**, 65-70(1929).—A report of two cases with clinical findings. J. B. BROWN

**The effects of anesthesia, operation and certain other factors on glucemia.** ERIC MEKIE AND HUGH MILLER. *Brit. Med. J.* **1929**, I, 244-7.—High pre-operative blood sugar may be found with acute infection, peritoneal irritation, shock and nervousness.

Following operations there is usually a rise in blood sugar, also with post-operative shock. The rise is slight with spinal anesthesia. J. B. BROWN

The influence of treatment with hypertonic sodium chloride solutions in patients with acute abdominal lesions. R. S. ANDERSON AND REED ROCKWOOD. *Surgery, General, and Obstet.* 49, 48-53(1929).—Ninety patients with low blood Cl associated with acute abdominal lesions were treated with intravenous hypertonic NaCl soln. with a resultant reduction of operative mortality of  $1/2$ . Fall in blood Cl parallels severity of toxemia. Compared with detn. of blood non-protein N and  $\text{CO}_2$  capacity, the Cl detn. is most significant. J. B. BROWN

The behavior of the blood sugar in the night and in the morning. HERMANN LANGE AND JACOB SCHLOSS. *Arch. expil. Path. Pharm.* 139, 274-89(1929).—Blood sugar was detd. at frequent intervals from 9 P. M. to 9 A. M. In 16 diabetic cases, the concn. of blood sugar began to increase suddenly some time between 3 A. M. and 5 A. M. There is a marked parallelism between the rate of increase and the attendant difficulty in carbohydrate metabolism. Data are also presented on 9 non-diabetic cases. B. C. BRUNSTETTER

Hemolytic poisons and the changes in the liver. B. ALTOSI. *Atti accad. Lincei* [6], 9, 358-63(1929).—Five series of expts. were made on dogs; 1st, ligation of the bile duct; 2nd, acute poisoning; 3rd, chronic poisoning; 4th, poisoning followed by ligation of the bile duct; 5th ligation, followed by poisoning. Case I. After 42 days ligation the animals were killed; they showed no notable changes either on the hepatic cells or on the erythrocytic app. Case II, A. With toluylenediamine, jaundice appeared at once; death occurred in 9 days. The liver had increased in size, and showed atrophy of the hepatic lobes; the Kupffer cells were pigmented with bile. B. Pyridine caused death in 5 days, little jaundice and no noticeable changes in hepatic cells; the Kupffer cells had increased in size and had excess red corpuscles. C. Tellurite caused death in 4 days; the only change was the deposition of black specks of Te in the Kupffer cells. The jaundice depends on the changes in the hepatic cells which are most affected by the diamine. Case III was similar to case II, except that death occurred after a longer period, and the changes were less marked. Case IV. With diamine and ligation after 18 days, the jaundice increased greatly after ligation. The autopsy showed enlargement, and fatty degeneration of the hepatic cells. Pyridine, followed by ligation after 26 days, caused slight jaundice, and pigmentation with bile as above. Tellurite with ligation showed no jaundice, but showed Te, as above. Case V. Diamine was given 12 days after ligation; jaundice was intense at first, but diminished even with increasing amts. of poison. Some atrophy was noted on autopsy, and some change in the hepatic cells. With pyridine, there was little jaundice, and autopsy showed slight changes in the hepatics, but heavy deposits of bile in the Kupffer cells. Evidently ligation after poisoning, by causing the most damage to the hepatics, caused the most changes, and indicate that these are involved intimately in the elimination of bile, and when they are destroyed the bile gets into the blood stream. A. W. CONTIERI

Comparative results of colloidal gold, colloidal mastic and colloidal benzoïn tests of cerebrospinal fluid. C. F. REYNER. *Arch. Dermatol. Syphilis* 1928, 833; *Rev. hyg. mèd. prév.* 51, 462-3.—In 2160 trials with cerebrospinal fluid, colloidal Au and colloidal mastic gave comparable results in 91.6% of the cases. Colloidal Au and colloidal benzoïn agreed in 71% while benzoïn and mastic agreed in 81% of the trials. Colloidal benzoïn was particularly effective in aiding the detection of syphilis of the nerves. Mastic was not specific. The use of both Au and benzoïn simultaneously is recommended. C. R. FELLERS

The lipolytic enzymes of blood, lymphocytes and the von Pirquet reaction in tuberculosis. GUEGUETCHKORIS. *Rev. Tuberc.* 9, 391(1928); *Rev. hyg. mèd. prév.* 51, 452.—Normal humans have a lipolytic index of 12-13 while in grave cases of tuberculosis the index is from 3 to 6. The prognosis is poor with a falling index. C. R. F.

Hypersensitiveness of the skin to substances that have a quinone structure. R. L. MAVER. *Klin. Wochschr.* 7, 1958-9(1928). MILTON HANKE

Hydrogen-ion concentration and the calcium and phosphorus content of the feces of rachitic children. THIRZA REDMAN. *Biochem. J.* 23, 256-60(1929); cf. *C. A.* 22, 2198.—There is a "certain degree of correlation" between  $p_H$  and the percentage of Ca in the feces of rachitic children. BENJAMIN HARROW

Idiopathic or hypoparathyroid tetany in children with special reference to certain psychic manifestations. W. RAY SHANNON. *Arch. Pediatrics* 46, 346-70(1929).—In idiopathic parathyroid tetany, psychic phenomena may predominate in the attack.

In 5 cases during the attack, the blood Ca ranged between 6.13 and 9.8 mg. per 100 cc. of serum. A bibliography (22 references) is appended. JOSEPH S. HEPBURN

Review of the dental literature on the etiology of dental caries. HAROLD J. NOYES. *Dental Cosmos* 71, 810-7(1929).—A review of chem. interest, with a bibliography.

JOSEPH S. HEPBURN  
The chloride content of the blood and its partition among its constituents in hemopathological, especially anemic, conditions. A. EUGSTER. *Z. klin. Med.* 107, 224-55 (1928).—A decrease in the hemoglobin is usually accompanied by a more or less marked increase in the chlorides of the whole blood. Whenever a marked decrease in hemoglobin occurs, e. g., in severe anemia, a relative displacement takes place between the hemoglobin and the NaCl of the erythrocytes. In nephritis with N retention, pneumonia and diabetes mellitus anemia occurs accompanied by a decrease in the chlorides of the serum and an increase in the chlorides of the erythrocytes. In uremia, the chloride content may be equal in serum and erythrocyte. J. S. H.

Anaphylactic studies with extracts of hydatid scolices. C. H. KELLAWAY. *Brit. J. Exptl. Path.* 10, 115-25(1929); cf. *C. A.* 22, 3217.—The general result of these expts is to bring the hydatid scolex into line with other helminths, the tape-worm and the fluke. The substances in scolex which are insol. in acetone but sol. in abs. alc. and which act as "partial antigens," causing sensitiveness but being unable to discharge it, may possibly owe their activity *in vivo* to union with some body protein in the guinea pig producing a foreign complex to which antibody can be produced. There is, however, in addn. a water-sol. substance present in saline exts. of scolices which can function as an anaphylactic antigen. Because of the difficulty of freeing scolices from the protein substances in hydatid fluid it is not certain that this substance is not derived from hydatid fluid. Host (sheep) serum protein is present in exts. of scolices and extn. with pure dry acetone and with abs. alc. does not guarantee its absence from the resulting exts. HARRIET F. HOLMES

Determination of fat cleavage in the duodenal juice for clinical research. KARL H. STAUDER. *Arch. Verdauungs-Krankh.* 45, 197-208(1929).—The lipase content of the fasting intestine was found to be practically const. In all normal cases, it was greater at the height of digestion than during fasting. There was no regularity in the findings on pathol. cases. Bile enhances fat cleavage to a greater degree in normal cases, than in pathol. ones. There is no relation between gastric acidity and fat digestion. FRANCES KRASNOW

Experimental cholecystopathy and the secretory function of the stomach. S. O. BADILKES. *Arch. Verdauungs-Krankh.* 45, 254-64(1929).—As a result of foreign bodies and inflammation of the gall bladder, there was a decrease in gastric secretion, in acid content and in the time of secretion. FRANCES KRASNOW

Studies on the acceleration and inhibition of hemolysis. I. The inhibition of saponin and taurocholate hemolysis by sucrose. J. FRANKLIN YEAGER. *Quart. J. Exptl. Physiol.* 19, 219-35(1929).—Curves are given expressing the relation between the amt. of isotonic NaCl and the amt. of isotonic sucrose in the hemolytic system and the value of the resistance const. for saponin and Na taurocholate hemolysis. Rate of change of the resistance const. is inversely proportional to the completeness of the system with respect to the electrolyte, NaCl. Neither saponin nor Na taurocholate will produce hemolysis in a system in which all of the electrolyte is replaced by isotonic sucrose. Such electrolyte-free systems have not been obtained, since the replacement of all the electrolyte NaCl of a human red cell suspension by isotonic sucrose itself results in hemolysis. The local inactivity of Na taurocholate in concns. of about 1 in 1000 passes through a max. and finally tends to disappear as increasingly greater amounts of isotonic sucrose are contained in the system. FRANCES KRASNOW

The effect of shivering on the respiratory quotient in pancreatic diabetes. I. L. CHAIKOFF AND J. J. R. MACLEOD. *Quart. J. Exptl. Physiol.* 19, 291-5(1929).—Shivering in response to colds raises the R. Q. and the O<sub>2</sub> consumption of normal and depancreatized dogs to a similar extent. There is no disturbance in the acid-base equil.; hence there is increased carbohydrate oxidation. The increase is marked at the beginning, returning to basal level although O<sub>2</sub> consumption is still maintained. This indicates that "oxidation of preformed carbohydrates is the only process which is stimulated when shivering starts but that a process of gluco-neogenesis sets in later and thus depresses the quotient although as much carbohydrate is still oxidized." FRANCES KRASNOW

The treatment of typhoid fever with detoxicated vaccine. W. B. WHERRY, T. J. LEBLANC, L. FOSHAY AND R. THOMAS. *J. Infectious Diseases* 43, 189-93(1928).—

By treating typhoid vaccines with formaldehyde according to Ramon's method they can be detoxicated so that 82 to 164 million can be injected into patients without any harm. Typhoid fever in patients treated with such vaccines showed a shorter course of the disease, less complications and a death rate of 0. JULIAN H. LEWIS

The approximation of the toxicity of diphtheria toxin *in vitro*. ARTHUR LOCKE AND E. R. MAIN. *J. Infectious Diseases* 43, 420-5(1928); cf. C. A. 22, 4624.—A simple, practicable method is reported, whereby the  $L_0$  titer of an unmodified diphtheria toxin may be predicted, *in vitro*, with an accuracy of 85 to 95%. The method is based on the use of a formula correlating the properties of toxicity and antitoxin-binding avidity. It consists of a modified flocculation titration, wherein the latter property is evaluated in terms of  $L_1$  titer and "unit flocculation time," the results being converted into toxicity units by reference to the basic formula. JULIAN H. LEWIS

The units of protective antibody in antipneumococcus serum and antibody solution. LLOYD D. FELTON. *J. Infectious Diseases* 43, 531-42(1928).—A method is outlined for the standardization of antipneumococcus serum and pneumococcus antibody concentrate in which the unit is that fraction of a cc. of serum or antibody soln. which will protect against 1,000,000 fatal doses of an 18-hr. serum broth culture of such virulence that 3-10 organisms injected intraperitoneally into a mouse result in death in 36-48 hrs. JULIAN H. LEWIS

Concentration of pneumococcus antibody. LLOYD D. FELTON. *J. Infectious Diseases* 43, 543-53(1928).—The antiserum is dild. with equal vols. of  $H_2O$ , warmed to 40° and 20% dry anhyd.  $Na_2SO_4$  added. The ppt. is dialyzed free of sulfate and the contents of the sac are adjusted to a  $pH$  of 4.6-4.8 at which point a ppt. of an inert protein and lipid is formed. The clear supernatant fluid is adjusted to  $pH$  6.8 and dild. 4-5 fold with cold distd.  $H_2O$ . The ppt. dissolved in NaCl is high in protective power and, for intravenous injection, is practically free from severe chill-producing characteristics. JULIAN H. LEWIS

The absence of heterophilic antigen in certain foods. I. DAVIDSOHN. *J. Infectious Diseases* 44, 44-6(1929).—Cabbage, lettuce, carrots, potatoes, wheat, corn and oats do not contain heterophilic antigen of the Forssman type. JULIAN H. LEWIS

Hemolysin and hemagglutinin for sheep corpuscles in human serums of all isoagglutinative groups. ETHEL B. PERRY AND G. BERNICE RHODES. *J. Infectious Diseases* 44, 65-7(1929).—Hemolysin for sheep corpuscles is present in human serums of all isoagglutinative groups, though not in all serums of any group, while the heterophilic hemagglutinin is present in nearly all human serums. The hemolysin is independent of the isoagglutinin and is absorbable by guinea-pig kidney or liver. JULIAN H. LEWIS

Hemolysin for sheep corpuscles in precipitin serums from rabbits. LUDVIG HEKTOEN AND ETHEL B. PERRY. *J. Infectious Diseases* 44, 68-72(1929).—Precipitin serums from rabbits immunized with egg white, cow milk, blood (beef, chicken, dog), sheep serum, swine euglobulin, human pseudoglobulin and hemoglobins, fibrinogens and thyroglobulins of many different species contain hemolysin for sheep corpuscles. Tests repeated after absorption of the serums with the homologous antigen and with sheep corpuscles indicate that the hemolysin is independent of the precipitin. The possibility of traces of lipid (also of other substances) must be considered since in the sepn. of serum proteins the lipids are known to be pptd. with the globulins. JULIAN H. LEWIS

The proteins of egg white. II. The transformation of crystallized ovalbumin into the noncrystallizable conalbumin. LUDVIG HEKTOEN AND ARTHUR G. COLB. *J. Infectious Diseases* 44, 165-6(1929); cf. C. A. 22, 4623.—Tests made with the precipitin reaction indicate that crystd. ovalbumin, when subjected to putrefactive processes, is not converted into conalbumin. It is also shown that such a putrefying soln. of ovalbumin loses its power to react with its sp. antiserum even while it still contains a considerable amt. of coagulable protein (cf. Sørensen and Høyrup, C. A. 12, 2575). JULIAN H. LEWIS

Immune reactions to acid-treated bacteria. An attempt to produce immunity without antibodies demonstrable *in vitro*. ORAN I. CUTLER. *J. Infectious Diseases* 44, 203-14(1929).—No support was obtained for the theory that artificial immunity could be attained without the presence of antibodies in the circulation, for when bacteria are treated with chemicals they appear to lose their ability to incite antibody production in close proportion to their power to produce immunity. When immunity to live typhoid bacilli was demonstrated, agglutinins for the organisms were also found, at least in low titer. Bacteria, which are not completely destroyed by chemicals with which they are treated, may be changed so that new antigens are formed, to which

rabbits respond by the production of antibodies sp. for the altered bacteria. Antibodies formed for typhoid bacilli treated with  $\text{HNO}_3$ , which were different from those formed for live organisms, were not demonstrated to be bactericidal for live bacteria. The antibodies formed for typhoid bacilli treated with 0.5 N acid appear to be the same whether  $\text{HNO}_3$  or  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$  or  $\text{AcOH}$  is used. JULIAN H. LEWIS

**Hypersensitiveness to diphtheria bacilli.** Passive transfer of types of immunity represented by different skin reactions. JAMES M. NEILL AND WM. L. FLEMING. *J. Infectious Diseases* 44, 224-34(1929). Quantitative correlation of the responses to diphtheria culture filtrate and to ragweed pollen extract in sensitized skin. *Ibid* 308-20. Lack of correlation between the responsiveness to histamine in the normal skin and to specific antigens in the sensitized skin. JAMES M. NEILL, WM. L. FLEMING AND LURLINE V. RICHARDSON. *Ibid* 321-6. Weak reactions to diphtheria bacteria and strong reactions to a diphtheroid. JAMES M. NEILL AND WM. L. FLEMING. *Ibid* 397-402. JULIAN H. LEWIS

**Anticomplementary power of heparin.** ENRIQUE E. ECKER AND PAUL GROSS. *J. Infectious Diseases* 44, 250-3(1929).—Heparin inhibits hemolysis in a hemolytic system because of action on complement. Apparently the third component of complement is affected. JULIAN H. LEWIS

**Preparations of specific serums and technic of agglutination test with *Pasteurella pestis* detoxified with formaldehyde.** A. BATCHELDER. *J. Infectious Diseases* 44, 402-7(1929). JULIAN H. LEWIS

**Incidence and properties of isohemolysins.** CORNELIA M. DOWNS, H. P. JONES AND KENNETH KOERBER. *J. Infectious Diseases* 44, 412-9(1929).—Isohemolysins were present in 65.9% of the serums from white persons and in 49.5% of the serums from Indians. The failure of hemolysin in the fresh serums tested seems to be due to the absence of hemolysin rather than of complement. Only a small percentage of the serums may be reactivated after heating by the addn. of complement. This is due to masking rather than to destruction of the hemolysin. A distinct but not type sp. inhibitory effect could be demonstrated by the addn. of heated serum to the active serum and cells. Isohemolysins behave like natural heterohemolysins and immune heterohemolysins in regard to absorption by their sp. cells in the cold and their dependence on complement. No concn. by pptn. methods could be demonstrated. No hemolysin for corpuscles contg. the C factor could be demonstrated. No hemolysis or agglutination was observed in testing serums of groups A, B and AB against cells of group O. JULIAN H. LEWIS

**The content of complement components in ammonium sulfate serum precipitated with ammonium sulfate.** H. TOKUNAGA. *Acta Schol. Med. Univ. Imp. Kyoto* 11, 587-9(1929); cf. *C. A.* 23, 3738.—Ammonium sulfate serum has been fractionated with ammonium sulfate. The albumin fraction contains either none or a trace of complement while the complement action of the globulin fraction is almost quantitative with heated serum. G. H. W. LEWIS

**Suprarenal insufficiency. IV. Blood sugar in suprarenalectomized rats.** I. C. WYMAN AND B. S. WALKER. *Am. J. Physiol.* 89, 215-22(1929).—Blood sugar in normal rats ranged from 61 to 110 mg. per 100 cc. blood; av. = 82. After the removal of both adrenals blood sugar fell to between 50 and 60 mg., coincident with the appearance of marked symptoms of subacute insufficiency. Successful cortical transplants maintained the blood sugar at the normal level. Conclusion: The cortex is concerned with the steady maintenance of a normal blood sugar level, while the medulla is an important adjunct for rapid adjustment under emergency conditions. J. F. LAMAN

**Carbohydrate metabolism in parathyroidectomized dogs.** C. I. REED. *Am. J. Physiol.* 89, 230-8(1929); cf. *C. A.* 22, 2981.—Glucose fed to or injected into dogs whose parathyroids had been removed protected them from tetany and prolonged their lives. Attacks of tetany were relieved by glucose administration. The effects of glucose injections on blood Ca and P were variable except that the Ca/P ratio was always increased. During attacks of tetany glucose tolerance was decreased. Carbohydrate metabolism seems to be involved in tetany. J. F. LAMAN

**Experimental studies on the existence of the hemolytic complement in the human cerebrospinal fluid. I. The complement in the normal human cerebrospinal fluid.** TAKESHI OKADA. *Sei-i-kwai Med. J.* 48, No. 3, 41-61, abstract sect. 5-6(1929).—O. wished to det. if hemolytic complement is present in normal human cerebrospinal fluid. Negative tests were obtained in the 15 cases studied. Normal spinal fluid shows complement activity after the addn. of human serum which has been inactivated by heating 15 min. at 51°. This activity is much decreased if the serum has been heated 30 min. at 51°. The complement activity of the spinal fluid is lost if it is heated

15 min. at 51°. The normal spinal fluid did not acquire any complement activity by adding "end piece" which is a portion of the complement. The addn. of "mid-piece," another portion of the complement, produced no effect, however, if the spinal fluid had been heated 15 min. at 51°. Normal spinal fluid may acquire a weak complement action after the addn. of inactive guinea-pig serum which has lost its complement by shaking. If the spinal fluid has been shaken beforehand, the mixt., after the addn. of the above guinea-pig serum is inactive. The normal spinal fluid acts as complement after the addn. of euglobulin pptd. from fresh serum with  $(\text{NH}_4)_2\text{SO}_4$ . Activity fails with pseudoglobulin or albumin. After heating at 51° for 15 min., normal spinal fluid is inactive after euglobulin addn. The failure of spinal fluid to act as a complement is due to the deficiency in the "mid-piece." Such a condition is termed "para-complementoid" by O. C. M. McCay

**Further studies on antitryptic activities of sera.** GORO YAMANAKA. *Sei-i-kwai Med. J.* 48, No. 3, 62-78, abstract sect. 6-7 (1929).—The av. antitrypsin value of normal rabbit serum is 164.1 when detd. by Wago's modification of the Fuld-Gross method. The same detn. for normal human sera yields an av. value of 164.9. In the female this increases during menstruation. In pathol. conditions the antitryptic activity of the sera is greater in acute diseases than in chronic ones. The antitryptic activities of rabbit sera increase after ultra-violet radiation or after treatment with the vaccine of *B. coli comm.* or egg albumin. These increases are accompanied by a leucocytosis in which there is an increase of both lymphocytes and large monocytes and a decrease in polymorphs. After the injection of adrenaline into normal rabbits the antitryptic value of the serum increased as the blood sugar rose and fell to normal parallel with the blood sugar. Adrenaline also produced a leucocytosis but the polymorphs increased and the lymphocytes and large monocytes decreased. During fasting the antitryptic activity of the serum decreases. C. M. McCay

**Interpretation of the values of the alkali reserve of the blood plasma during ketacidoses.** PAUL CRISTOL. *Compt. rend.* 188, 1451-2 (1929).—It has been reported frequently that in cases of pronounced keto-acidosis a practically normal alkali reserve was found according to the Van Slyke method. This is due to an inaccuracy of this method: acetoacetic acid which is accumulated in the blood undergoes extensive decarboxylation in the Van Slyke app.; thus the  $\text{CO}_2$  values found are not due solely to the alk. reserve but also to the  $\text{CO}_2$  split off from acetoacetic acid. G. TOENNIES

**Relation of bacteria to so-called "chemical pneumonia."** A. R. KOONTZ AND M. S. ALLEN. *J. Exptl. Med.* 50, 67-79 (1929). C. J. WEST

**Immunological studies in relation to the suprarenal gland. IV. The effect of repeated injections of epinephrine on the hemolysis formation in suprarenalectomized rats.** DAVID PERLA AND J. MARMORSTON-GOTTESMAN. *J. Exptl. Med.* 50, 87-92 (1929); cf. *C. A.* 22, 3696. —Adrenaline dild. with physiol. salt soln. or with isotonic glucose solns. and injected in amts. of 0.2 mg. per kg. twice daily into suprarenalectomized rats raises their antibody-forming capacity. This result is not entirely dependent on the effect of the dilg. fluid. V. The effect of repeated injections of solutions containing sodium salts and glucose on the hemolysin formation of normal and suprarenalectomized rats. J. MARMORSTON-GOTTESMAN AND D. PERLA. *Ibid* 93-102.—Suprarenalectomy is followed by a disturbance in the antibody-forming mechanism of the body. The suprarenal gland plays a role in the  $\text{H}_2\text{O}$  metabolism of the tissues. Restoration of the  $\text{H}_2\text{O}$  exchange in the tissues to a normal level is sufficient to raise the antibody-forming capacity to normal. Repeated injections of large amts. of isotonic NaCl or  $\text{AcONa}$  solns. restore the antibody titer to normal. The effect of these solns. is not due to diuresis alone, since isotonic glucose soln. does not affect the titer, nor to the Na alone, since hypertonic solns. of NaCl in small vol. have little influence on the titer. Both the Na ion and the  $\text{H}_2\text{O}$  volume are necessary in the restoration of the titer. C. J. WEST

**Biometry of calcium, inorganic phosphorus, cholesterol and lecithin in the blood of rabbits. IV. Effects of a malignant tumor.** ALVIN R. HARNES. *J. Exptl. Med.* 50, 109-20 (1929); cf. *C. A.* 23, 3505.—Expts. are reported in which it is shown that the Ca, inorg. P, cholesterol and lecithin in the blood of normal rabbits were influenced by inoculation with a malignant tumor. Animals in which death was due to tumor showed a marked increase in inorg. P of blood serum and cholesterol of whole blood following inoculation. The ratios of cholesterol to Ca and lecithin to Ca increased in trend, while the Ca to inorg. P, lecithin to cholesterol and lecithin to inorg. P ratios showed a marked decrease in trend. The ratios cholesterol-lecithin were all negative. C. J. WEST

## H—PHARMACOLOGY

A. N. RICHARDS

**Action of ephedrine on intestine and bronchi.** J. T. HALSEY. *Proc. Soc. Exptl. Biol. Med.* 26, 16-7(1928).—Contrary to the findings of Chen (*C. A.* 20, 1870, 21, 2321) and of Kreitmair (*C. A.* 21, 1307, 1498) in over 100 expts. no evidence of a depressant action of ephedrine on isolated rabbit intestine was found. In a limited no. of expts. a bronchodilatory effect of ephedrine was observed; possibly this effect is produced only under certain conditions. C. V. BAILEY

**Magnesium sulfate as a factor in retention of calcium and phosphorus in cattle.** L. S. PALMER, C. H. ECKLES AND D. J. SCHUTTE. *Proc. Soc. Exptl. Biol. Med.* 26, 58-62(1928).—Intakes of  $MgSO_4$  comparable to that consumed by cattle in regions where they are forced to drink water contg. this salt may cause serious and continuous losses of Ca from the body tissues when the P content of the ration is low. The effect on P balance seemed to be detrimental only in the younger animals. C. V. B

**Effect of foreign protein and of insulin administered by mouth after oxgall.** M. F. GUYER AND P. E. CLAUS. *Proc. Soc. Exptl. Biol. Med.* 26, 65-7(1928).—Lens protein (*beta crystallin*) given by mouth following oral doses of oxgall resulted in the production of lens precipitins in rabbits. Insulin similarly administered yielded negative results in 3 rabbits but gave positive shock effects in 5 out of 6 guinea pigs. C. V. B

**Adrenaline and fatiguability of muscle of adrenalectomized rats.** L. B. NICE, D. S. GREENBERG AND S. L. GREENBERG. *Proc. Soc. Exptl. Biol. Med.* 26, 136-7(1928).—A series of adrenalectomized rats were given subcutaneously 1 cc of 1:50,000 adrenaline chloride (Park, Davis & Co.) daily for periods of 7 days to 14 weeks. The animals were then urethanized and a fatigue curve of a gastrocnemius muscle was obtained. There was no evidence of increased work done by the muscles of these rats after the daily administration of adrenaline. C. V. BAILEY

**Chemical and pathological changes in livers of copper-fed animals.** WM C VON GLAHN AND FREDERICK B. FLINN. *Proc. Soc. Exptl. Biol. Med.* 26, 200(1928).—Cu does not cause pigmentation or cirrhosis of the livers of rabbits, rats or guinea pigs. The pigment found in the liver of rabbits is probably of exogenous origin. C. V. BAILEY

**Effects of aconitine in the rat.** R. CUNNINGHAM, ELIZABETH CLARK AND M. O. LEE. *Proc. Soc. Exptl. Biol. Med.* 26, 221-2(1928).—The lethal dose of aconitine for the adult rat is 0.026 mg.; the minimum lethal dose is approx. 0.025 mg. Urethan anesthesia exerts a definite effect in preventing death from what would otherwise be lethal doses of aconitine. C. V. BAILEY

**Blood pressure in unanesthetized animals affected by "vasopressin," "oxytocin," pituitary extract and other drugs.** CHARLES M. GRUBER. *Proc. Soc. Exptl. Biol. Med.* 26, 243-4(1928).—In the dog and the cat pituitary ext. caused a rise in blood pressure; "oxytocin" had no definite effect. Acetylcholine caused a decreased blood pressure and an increase after the injection of atropine in dogs. "Vasopressin" caused its typical fall in blood pressure after atropine; its action is probably not due to choline or histamine. C. V. BAILEY

**Effect of methanol and ethyl alcohol mixtures on behavior of rats in a maze.** DAVID I. MACHT AND HARRIET LEACH. *Proc. Soc. Exptl. Biol. Med.* 26, 330-1(1929).—The intraperitoneal injection of 2 cc. of 2 to 4% EtOH was definitely depressant, similar doses of MeOH were less depressant and showed a definite stimulating effect. Half the above doses, injected synchronously, produced a very marked depression. C. V. BAILEY

**Duration of anticoagulant action of heparin in vivo in relation to dosage.** PAUL GROSS. *Proc. Soc. Exptl. Biol. Med.* 26, 383-7(1929).—The intravenous injection of heparin is followed by an immediate increase in clotting time; return to normal is very rapid for  $\frac{1}{3}$  of the duration of the heparin action and then progressively slow. There is an approx. relationship between the dose of heparin per kg. of body wt and the duration of the heparin effect in rabbits. C. V. BAILEY

**Effect of neoarsphenamine on the number of blood platelets.** JUI-WU MU. *Proc. Soc. Exptl. Biol. Med.* 26, 407-9(1929).—Novarsenobenzol "Billon" was given intravenously in doses of 0.1 g. per kg. of body wt. In 14 patients the platelets were counted before the injection and at intervals from 10 min. to 1 day after the injection for 5 days. In 10 cases diminution of platelets occurred during the 1st day; this was followed by a moderate thrombocytosis never exceeding 450,000 platelets per cu. mm. The normal count is 350,000. The variations were more marked in cases developing a febrile reaction. C. V. BAILEY

**Responses of the kidney and spleen to subcutaneously injected adrenaline.** THEODORE KOPPÁNYI AND M. S. DOOLEY. *Proc. Soc. Exptl. Biol. Med.* 26, 443-5(1929).—Massage of areas subcutaneously injected with adrenaline may produce marked localized vasoconstriction; the general blood pressure may remain unaffected; the kidney and spleen become markedly constricted. The vol. changes of these organs may be used as a reliable criterion in the bioassay of adrenaline. C. V. BAILEY

**Effect of feeding small doses of potassium iodide on the thyroid gland.** S. H. GRAY AND J. RABINOVITCH. *Proc. Soc. Exptl. Biol. Med.* 26, 468-71(1929).—The daily feeding of 0.0001 g. of KI to guinea pigs does not increase the no. of mitoses and does not affect the structure of the thyroid gland; 0.001 g. of KI daily causes a slight increase in mitoses and produces an otherwise histologically active thyroid gland. The gland is stimulated in all its histological phases when the daily dose is 0.01 g. of KI. C. V. BAILEY

**Hyperglucemia following the portal injection of insulin.** WM. S. COLLINS AND JOHN R. MURLIN. *Proc. Soc. Exptl. Biol. Med.* 26, 485-90(1929).—Dogs, starved 24 hrs. and under amnytal anesthesia, were used. Blood sugar was detd. by the Folin-Wu method. Each expt. consisted of alternate injection of the same amt. of insulin into the portal or jugular vein at weekly intervals. The dose of insulin was usually 0.1 unit per kg. of body wt.; the vol. never exceeded 1 cc. In every expt. the portal injection of insulin resulted in a sharp rise in the blood sugar of 20 to 80 mg. per 100 cc., the rise occurred within 5 min. and was followed by a rapid decline. No such rise occurred following the systemic injection of insulin. The phenomenon results from either the discharge of an antinsulin substance in the liver, or the insulin causes glycogenolysis in the liver; the latter is probably true. C. V. BAILEY

**The action of calcium on the vertebrate heart.** WRAY LLOYD. *Proc. Soc. Exptl. Biol. Med.* 26, 506-8(1929).—The hearts of 1 turtle, 2 cats, 3 dogs and 46 rabbits were perfused with oxygenated Locke soln. by a modified Langendorff technic. Ca was introduced into the perfusing fluid in varying quantities of a 0.25% soln. of  $\text{CaCl}_2$ . The characteristic and practically const. effect was cessation of the heart action in systole with a well-marked Ca rigor. C. V. BAILEY

**Anticomplementary action of purified heparin.** PAUL GROSS AND E. E. ECKER. *Proc. Soc. Exptl. Biol. Med.* 26, 4508-9(1929).—Heparin, purified by the recent method of Howell, operates upon complement in the same qual. manner as does unpurified heparin, namely upon the 3rd component. The purified product is definitely increased in activity. C. V. BAILEY

**Effect of calcium on the action of pilocarpine and atropine.** WM. SALANT AND HENRY WASHEIM, JR. *Proc. Soc. Exptl. Biol. Med.* 26, 512-5(1929).—Pilocarpine, in the absence of Ca, stimulates intestinal movements; tonus is only slightly increased. Excess Ca depresses the effect of pilocarpine on the intestine. Pilocarpine sensitizes the intestine to Ca. Pilocarpine in Ringer soln. minus Ca is without effect on the isolated frog heart. Excess Ca antagonizes the depression produced by pilocarpine. The action of atropine is reversed by Ca deficiency; this causes a slowing of the heart. C. V. BAILEY

**Toxicity of eucupine in local analgesia.** RAYMOND J. MILLZNER AND CHAUNCEY D. LEAKE. *Proc. Soc. Exptl. Biol. Med.* 26, 526-7(1929).—Solns. contg. eucupine give satisfactory prolonged analgesia, but the severe local reactions such as erythema, induration, delayed healing and sloughing preclude it for clinical use. C. V. B.

**The action of volatile fatty acids on the gastric motor mechanism in dogs.** ROBERT L. WILDER AND FREDERICK W. SCHULTZ. *Proc. Soc. Exptl. Biol. Med.* 26, 624-5(1929).—The introduction into the quiescent stomach of a 0.5% soln. of butyric acid caused an immediate fall in gastric tonus and an inhibition of tonus rhythm lasting from 1 to 15 min. Caproic and caprylic acids have similar but less marked effects. C. V. BAILEY

**Some further observations on sodium isoamylethylbarbiturate as a laboratory anesthetic.** CHARLES C. LEIB AND MICHAEL G. MULINOS. *Proc. Soc. Exptl. Biol. Med.* 26, 709-11(1929).—Solns. of Na amnytal injected intravenously depress the circulation; they cause prolonged but temporary paralysis of the vagus to the heart. The solns. show no increased toxicity after standing 2 months. C. V. BAILEY

**The effect of synthalin on the respiratory quotient of the diabetic patient.** W. G. KARR, C. SCHUMANN AND O. H. PETTY. *Arch. Internal Med.* 43, 384-92(1929).—When synthalin is given before a dextrose meal, there is increased utilization of carbohydrate as indicated by increased respiratory quotient. In some cases there is increased dextrose tolerance as measured by sugar in the blood and urine. J. B. B.

**Opium addiction. IV. The blood of the human addict during the administration of morphine.** WALTER G. KARR, ARTHUR B. LIGHT AND EDWARD G. TORRANCE. *Arch. Internal Med.* 43, 684-90(1929).—There was a tendency toward low red cell and high leucocyte count, and also high cholesterol and diminished phosphate in addicts receiving morphine sulfate hypodermically. Lactic acid was uniformly high. No other changes of consequence were noted. **V. Miscellaneous observations on human addicts during the administration of morphine.** ARTHUR B. LIGHT AND EDWARD G. TORRANCE. *Ibid* 878-89.—During administration of morphine to human addicts no changes from the normal were observed in the stomach, kidney, liver, basal metabolism, thymus, temp. and dextrose response to adrenalin and to morphine. The exceptions noted were a slight delay in response of gastric secretion to a test meal, albuminuria in 17% of cases, wide variations of basal metabolism although the average was normal and a delay in the return of blood sugar to normal after giving dextrose by mouth. J. B. BROWN.

**The effect of magnesium salts on blood sugar concentration.** S. LÄNG AND L. RIGÖ. *Arch. expl. Path. Pharmacol.* 139, 1-9(1929).— $MgCl_2 \cdot 6H_2O$  in doses of 0.0025-0.10 g. per kg. and  $MgSO_4 \cdot 7H_2O$  in doses of 0.0025-0.005 g. per kg. were injected subcutaneously into rabbits, causing a decrease in blood sugar. Larger doses caused an increase. B. C. BRUNSTETTER.

**Pharmacological studies on the bronchial musculature. I. Methods.** KURT TIEFENSEE. *Arch. expl. Path. Pharmacol.* 139, 129-38(1929). **II. The importance of the condition of the blood for the tonus of the bronchial muscles and their response to poisons.** *Ibid* 139-53.—Displacement of blood  $p_H$  to the alk. side increases the strength of pilocarpine spasms; increased acidity of the blood causes pilocarpine spasms to be weakened or to disappear. There is no change in the action of pilocarpine on the heart. Changes in the alkali reserve of the blood are without effect on the reaction of the bronchial muscles to pilocarpine. Atropine annuls the effect of pilocarpine on the bronchioles and on the heart, under all conditions. The paralytic action of adrenalin could be demonstrated only on contracted bronchial muscles. T. discusses the relation between the results of this work and the onset of asthma. B. C. B.

**The effect of choline on gas exchange.** H. TANGL. *Arch. expl. Path. Pharmacol.* 139, 220-5(1929).—Choline, subcutaneously injected into rats in doses from 20-80 mg., increases metabolism. The max. effect occurs 2-6 hrs. after injection, at a time when, according to other authors, hypoglycemia is most pronounced. B. C. B.

**The effect of secretin on gaseous exchange.** H. TANGL AND F. THAN. *Arch. expl. Path. Pharmacol.* 139, 226-30(1929).—Injection of secretin into rats increases the respiratory quotient because of decreased  $O_2$  consumption. B. C. BRUNSTETTER.

**The cholagog action of magnesium chloride.** ÉTIENNE CHABROL AND MAURICE MAXIMIN. *Compt. rend. soc. biol.* 100, 3-5(1929).—Intravenous injection of  $MgCl_2$  into dogs in a dose of 0.07 g. per kg. had no effect on the rate of bile secretion but a dose of 0.01 g. per kg. caused a doubling of the rate within half an hr. B. C. B.

**The hyperglucidemic action of adrenaline.** GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend. soc. biol.* 100, 1200-2(1929); cf. *C. A.* 21, 2311; 22, 3185, 23, 627.—The glucemia value obtained after pptn. by tungstic acid is higher than that obtained after pptn. by  $Hg(NO_3)_2$ . The former is considered to be due to glucose and "glucide x"; the latter, to glucose alone, since "glucide x" is pptd. by  $Hg(NO_3)_2$ . The diff. in these values gives an approx. measure of "glucide x." The subcutaneous injection of adrenaline into dogs (1 mg. per kg.) caused a greater increase in "glucide x" than in glucose, not only in plasma but in whole blood. Compression of the portal vein, and injection of morphine caused an increase in glucose, but had no effect on "glucide x." B. C. BRUNSTETTER.

**The repartition of glucose between cells and plasma.** GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend. soc. biol.* 101, 171-3(1929).—After injection of 45 units of insulin into dogs there were no immediate changes in cellular glucides, though marked decreases occurred in the plasma glucides; after  $1\frac{1}{2}$  hr. the concn. of glucides in plasma and cells became equal. B. C. BRUNSTETTER.

**The hypoglycidemic action of insulin.** GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend. soc. biol.* 101, 173-5(1929); cf. *C. A.* 23, 627.—After injection of large doses of insulin into dogs, the diff. in reducing power of blood or plasma filtrates from tungstic acid and  $Hg(NO_3)_2$  pptns. rapidly decreases to approx. zero. This is regarded as additional proof of the glucidic nature of "glucide x." B. C. BRUNSTETTER.

**A fatal case of insulin poisoning.** BJARNE DAHL. *Norsk Mag. Laegevidenskab* p. 89, 40-55(1928).—D. describes the first fatal case of insulin poisoning in Scandinavia.

The patient failed at one dinner to eat the calcd. portion of carbohydrate, and that is supposed to be the cause of death. ARNE DROGSETH

**Development of therapeutics during the 16th to 18th centuries.** WINKLER. *Pharm. Monatsh.* 10, 112-3 (1929).—An address. W. O. E.

**The pharmacology of the alkaloids of ergot.** E. ROTHLIN. *Arch. expl. Path. Pharmacol.* 138, 115 (1928); *Squibb Abstract Bull.* 2, A-31 (1929).—The estn. of the pharmacol. activity of the ergot alkaloids requiring further data in view of the contrasting results reported by various writers, R. undertook the study of the 2 pairs of ergot alkaloids, *ergotinine* and *ergotoxine* (ergotinine plus 1 mol. water yields hydroergotinine or ergotoxine; the action is reversible); and ergotaminine and ergotamine (isomers). No confirmatory evidence was procured for the contention that ergotoxine has less pharmacol. action than ergotamine. Rather the 2 are equiv. in effect, the stimulation threshold for both being very high; in isolated guinea-pig uteri the action of either in 1 100-200,000,000 is equal to that of histamine. For ergotamine activity may be expressed as 1, that of ergotaminine as  $\frac{1}{10}$ ; ergotoxine 1, and ergotinine  $\frac{1}{200-300}$ ; for the tartrates the pharmacol. action of ergotamine and ergotoxine is equal, while ergotaminine displays  $\frac{1}{4}$  of the activity of the above and ergotinine  $\frac{1}{100}$ . C. R. F.

**The intensive treatment of kala-azar by neostibosan.** II. L. EVERARD NAPIER AND M. N. MULLICK. *Indian Med. Gaz.* 64, 314-5 (1929).—The subsequent history is given of 30 cases considered in the previous paper. FREDERICK G. GERMUTH

**An experimental study of some bismuth compounds of arsenic acids from the point of view of their therapeutic action in experimental syphilis.** C. LEVADITI. *Brit. J. Ven. Dis.* 4, 25-43 (1928); *Bull. Hyg.* 3, 874 (1928).—A study of sol. bistoal,  $C_6H_5(OH)(NHCOCH_3)AsO_3Bi(OH)_2$ , shows that 0.005 g. per kg. injected intramuscularly has remarkable therapeutic action, sterilizing with a dose that is  $\frac{1}{35}$  of the max. tolerated. Its therapeutic index is more favorable than that of the insol. form, which has an index of  $\frac{1}{10}$ . When taken by mouth 0.217 g. per kg. was sterilizing. Bismuth arsaniolate in a 10% oily suspension gave results equal to those of bistoal with the advantage of being painless. Bismuth tryparsamide, when given in an oily suspension, is less active than the two previous compds. GEORGE R. GREENBANK

**Therapeutic effect of the pyridine series.** A. BINZ AND C. RATH. *Tierarztl. Rundschau* 1928, No. 48, 3-7; *Chem. Zentr.* 1928, I, 1547; cf. *C. A.* 23, 1686.—Compds. contg. As united with a heterocyclic compd. such as pyridine should prove better than asphenamine.  $C_6H_5H_4NOI$  is useful in treating coccus infection. F. P. G.

**Insulin and gluconeogenesis.** MAURICE W. GOLDBLATT. *Biochem. J.* 23, 243-55 (1929).—Insulin can stimulate the new formation of glycogen from endogenous sources. The theory that insulin inhibits gluconeogenesis is considered untenable. B. H.

**Formic acid in its therapeutic relation to joint diseases.** H. M. SYLVESTER. *J. Am. Inst. Homeopathy* 22, 570-86 (1929).—Minute doses of  $HCOOH$ , administered intravenously or hypodermically, may benefit the periarticular tissues; but the success is questionable or negative if the inflammatory infiltrate has become definitely organized into a fibrotic mass. Synovitis responds readily, while the bony structures do not respond. The cartilaginous parts are influenced only in the very earliest stages of inflammation. JOSEPH S. HEPBURN

**Recent advances in therapeutics.** DAVID ANCHEL. *J. Am. Inst. Homeopathy* 22, 617-21 (1929).—A review, with bibliography, of recent work on the parathyroid hormone, ephedrine, cardiazole and novasurol. JOSEPH S. HEPBURN

**The action and uses of Cocculus.** L. J. BOYD. *J. Am. Inst. Homeopathy* 22, 653-5 (1929).—*Cocculus indicus* and its active principle, picrotoxin, are of value in cases of autonomic imbalance, especially when gastroenteric symptoms are also present. JOSEPH S. HEPBURN

**Drug pathology.** ALBERT E. HINSDALE. *J. Am. Inst. Homeopathy* 22, 683-746 (1929).—A description of the changes produced in exptl. animals by toxic (usually fatal) doses of 38 elements, compds. and drugs. The histological changes are illustrated by 51 cuts. JOSEPH S. HEPBURN

**Pharmacology.** ALBERT E. HINSDALE. *J. Am. Inst. Homeopathy* 22, 747-59 (1929).—An account (published posthumously) of original studies on the pharmacology of 15 compds. and drugs. JOSEPH S. HEPBURN

**Insulin hypoglycemia in man.** III. Behavior of the protein fraction of the blood, the bilirubin, the concentration and coagulation of the blood, especially in diseases of the liver. O. KLEIN AND M. KMENT. *Z. klin. Med.* 107, 476-87 (1928).—In patients with liver diseases, insulin shock produced the following blood changes: (1) a decrease in the bilirubin content, (2) a decrease in the coagulation time, (3) an increase in the total protein content of the serum, (4) an abs., and frequently a relative, increase in

the fibrinogen content of the plasma, (5) frequently an increase in the plasma globulin, (6) certain series of changes in plasma vol., blood concn. and vol. of the individual erythrocyte.

JOSEPH S. HEPBURN

**Influence of "Moorbehandlung" on the acid content of the gastric juice.** G. I. LEWIN. *Arch. Verdaunungs-Krankh.* 45, 59-66(1929).—"Moor" has a depressing effect on the acid secretion in the greater number of cases. Temp. is not the detg factor. The effect probably depends upon the mineral content of the "Moor," which stimulates the end organs in the skin and indirectly the vegetative nerve reflexes.

FRANCES KRASNOW

**Fractional removal of stomach contents. The action of atropine on the gastric secretion.** EMIL KELLERMANN. *Arch. Verdaunungs-Krankh.* 45, 67-80(1929).—Atropine in small doses effects a decrease in the free HCl; with large doses the fall is not great, but the emptying time is lengthened. The action is similar in hyperacidity, anacidity and normal cases. The backflow of intestinal juice is regularly inhibited by atropine.

FRANCES KRASNOW

**Strychnine in the treatment of gastric ulcers.** D. A. KOGAN. *Arch. Verdaunungs-Krankh.* 45, 231-5(1929).—Strychnine in combination with other treatment is of value.

FRANCES KRASNOW

**The influence of continuous subcutaneous injections of strychnine on gastric function. Observations by continuous sampling.** D. A. KOGAN. *Arch. Verdaunungs-Krankh.* 45, 235-8(1929).—Strychnine has no influence in achlorhydria. It increases the acidity in hypoacidity, in normal cases and even more in hyperacidity. It also strengthens gastric motility.

FRANCES KRASNOW

**Experiments with adrenaline.** W. BURRIDGE AND D. N. SETH. *Quart J. Exptl. Physiol.* 19, 201-14(1929).—At all dilns. ( $10^{-12}$  to  $10^{-4}$ ) adrenaline is an augmentor. At low dilns. ( $10^{-4}$  to  $10^{-6}$ ) it also has a depressing action. The drug in a diln. of 1 part in 10 millions was shown to revive an exhausted heart, to make an exhausted heart worse, to accelerate or not to accelerate, to produce tone or not to produce tone, according to exptl. conditions.

FRANCES KRASNOW

**The action of adrenaline and of certain drugs upon the isolated crustacean heart.** W. A. BAIN. *Quart. J. Exptl. Physiol.* 19, 297-307(1929).—A method for the perfusion of the isolated heart (crabs, *Maia squinado*, *Cancer pagurus* and *Carcinus maenas*) is described. Adrenaline produces a marked acceleration of the rhythm and an increase in tone of the heart muscle; in addn. in cancer, there is a pronounced increase in the amplitude of the beats. This action is not reversible. Ephedrine has no effect, ergotoxine has a depressant action but does not antagonize or reverse the action of adrenaline. Pilocarpine acts similarly to adrenaline. Atropine antagonizes the effect of pilocarpine.

FRANCES KRASNOW

**Influence of phosphorus on the state of the carbon and oxidation quotient of the urine.** HISAO KUBO. *Arch. path. Anat. (Virchow's)* 272, 504-30(1929).—The introduction of P in exptl. animals in such amts. as to cause no symptoms or at the most only mild poisoning, causes no consistent change in the C:N ratio in the urine. In P poisoning leading to death in 2-10 days the C:N ratio remains practically unaltered during the first few days, although occasionally slight increases or decreases of the quotient occur. If the animals live longer than this period, a decrease in the quotient occurs, which is attributable to an increase in urinary N. In severe acute, but non-fatal P poisoning, the quotient is similar at first to that seen in acute fatal poisoning, but after this the quotient rises to a point higher than the original normal value. Later it sinks back to the original figure. The O:N ratio behaves similarly, but does not exactly parallel the C:N urinary quotient.

E. R. LONG

**The pressure-volume curve of the peripheral blood vessels. III. The influence of drugs.** S. SUGIYAMA. *Acta Schol. Med. Univ. Imp. Kyoto* 11, 579-86(1929).—Adrenaline chloride, camphor and caffeine sodium benzoate administered intravenously decreased the dilatibility while strychnine nitrate and pilocarpine-HCl made no appreciable change. Hypotonal, pantopon and highly concd. d-glucose soln. caused a small increase.

G. H. W. LUCAS

**Adrenaline and hyperglucemia.** G. S. EADIE. *Am. J. Physiol.* 89, 48-9(1929).—One and one-half hr. after the administration of adrenaline to fasted cats under amylal anesthesia the glycogen content of the muscles was unaltered while liver glycogen was reduced almost to zero.

J. F. LYMAN

**The effects of insulin on parathyroidectomized dogs.** C. I. REED. *Am. J. Physiol.* 89, 239-42(1929).—Insulin in normal and in parathyroidectomized dogs, not in tetany, increased blood Ca and decreased blood inorg. phosphate. Insulin relieved parathyroid tetany, usually completely. After insulin administration in

tetany the inorg. phosphates of the blood decreased, blood Ca responded variably, but the Ca:P ratio was always increased. J. F. LYMAN

**The passage of hydrogen sulfide into the joint cavities.** MARIANO MESSINI. *Boll. so. ital. biol. sper.* 4, 97-8 (1929).—Colloidal S prepd. by the Wachenroder method was introduced by various routes at regular intervals into rabbits. A suspension of  $\text{PbCO}_3$  was injected into various parts of the animal. The  $\text{H}_2\text{S}$  formed by the reduction of S reacted with the Pb to form black  $\text{PbS}$ . The max. intensity was observed in the pleural cavity, joint cavity, in the muscles and under the skin. The reaction was more intense when the S was given intravenously than when given by the gastric, intramuscular or subcutaneous routes. In interpreting the therapeutic efficiency of colloidal S, the action of  $\text{H}_2\text{S}$  which passes into the joint cavities should be considered.

PETER MASUCCI

**A pharmacodynamic study of some phenylcholines and homologous substances.** Y. DE LESTRANGE AND JEANNE LÉVY. *Bull. sci. pharmacol.* 36, 353-79 (1929).—[ $\alpha$ -(Hydroxymethyl)benzyl]trimethylammonium chloride ( $\alpha$ -phenylcholine) ( $\text{PhCH}(\text{CH}_2\text{OH})\text{NMe}_3\text{Cl}$ ) (I), m. 157°, was obtained by reduction of phenyldimethylaminoacetic ester (40 g.) with Na and EtOH, which gives 20 g. phenyldimethylaminoethanol,  $b_{18}$  148.5°. The methiodide m. 100°. The phenyldimethylaminoethanol acetate b. 142-3° in the vacuum; its HCl salt m. 112°. I produces in the dog a decrease in the arterial pressure and an increase of peristalsis. In the isolated intestine, the tension is increased by small and reduced by large doses; then the peristalsis is inhibited. [ $\alpha$ -(Hydroxymethyl)phenethyl]trimethylammonium chloride ( $\alpha$ -benzylcholine) ( $\text{PhCH}_2\text{CH}(\text{CH}_2\text{OH})\text{NMe}_3\text{Cl}$ ) (II), m. 196°, is prepd. from dimethylaminophenylpropanol. Et phenyldimethylaminopropionate (III) is prepd. as follows: the bisulfite compd. of phenylpropionaldehyde is treated with KCN, then with a soln. of 0.5 mol.  $\text{Me}_2\text{NH}$  in  $\text{C}_6\text{H}_6$ ; the product is dissolved in HCl, washed with  $\text{Et}_2\text{O}$  and the base isolated with  $\text{Na}_2\text{CO}_3$ . The phenyldimethylaminopropionitrile  $b_{20}$  140-50°. The hydrochloride m. 118-20° (decompn.). The acid m. 95°. When reduced with Na, III gives phenyldimethylaminopropanol. The methiodide m. 198-200°. II produces in large dose a slight decrease of the tonus and excitation of peristalsis in the isolated intestine and strong contractions of the isolated uterus. ( $\beta$ -Hydroxyphenethyl)trimethylammonium chloride ( $\beta$ -phenylcholine) (IV), m. 218°, was prepd. from phenylethanol, 100 g. of which gives at 50 mm. pressure and 350-80° 70 g. styrene, b. 145-6°,  $b_{23}$  54°. Fifty g. styrene gives 30 g. phenyldimethylaminoethanol (V),  $b_{18}$  139°, through the iodohydrin. The acetate of V, m. 201°, benzoate, m. 210°, phenylacetate, m. 182°, methiodide, m. 223° (acetate, m. 194°, phenylacetate, m. 156°). IV exerts a hypertension in animals of warm blood and inhibition of the peristalsis. In the isolated uterus it produces contractions. In the frog, a curare-like effect was observed. ( $\beta$ -Hydroxy-*p*-methoxyphenethyl)trimethylammonium chloride ( $\beta$ -*p*-anisylcholine) (VI), m. 184°. AcH and  $\text{CH}_3\text{OC}_6\text{H}_4\text{MgBr}$  give *p*-anisylmethylcarbinol and methoxystryrene. The latter is treated with I and HgO, and the iodohydrin thus obtained is treated with  $\text{NHMe}_3$ , giving *p*-anisyl-dimethylaminoethanol, whose benzoate-HCl m. 163°. VI decreases the tonus and peristalsis of the isolated intestine. The ( $\beta$ -hydroxy- $\alpha$ -methylphenethyl)trimethylammonium chloride decreases the tonus and the peristalsis of the isolated intestine and inhibits the contractions of the uterus. ( $\beta$ -Hydroxy- $\gamma$ -phenylpropyl)dimethylamine,  $b_{23}$  123°, (methiodide, m. 148°). Methochloride, ( $\beta$ -benzylcholine) increases the tonus and peristalsis of the intestine and produces contractions in the insulated uterus. The 1-phenyl-4-dimethylamino-3-butanol b. 152-3°, the methiodide b. 171°. ( $\beta$ -Hydroxy- $\delta$ -phenylbutyl)trimethylammonium chloride ( $\beta$ -phenethylcholine), b. 176°, reduces the arterial pressure and excites the peristalsis. The contractive action on the uterus is weak. ( $\beta$ -Hydroxy- $\alpha$ -phenylpropyl)trimethylammonium chloride m. 220°; the iodide m. 228.9°. The former has a slightly reducing action on the blood pressure and no influence on the peristalsis. In the isolated intestine the peristalsis is increased, the tonus increased by small, decreased by large doses. In the uterus it produces contractions. ( $\beta$ -Hydroxy- $\beta$ -methylphenethyl)trimethylammonium chloride m. 244°. It decreases the blood pressure and produces peristalsis. It has no influence on the isolated intestine and produces contractions of the uterus. (2-Hydroxycyclohexyl)trimethylammonium chloride m. 250. It produces peristalsis in the isolated intestine and contractions of the uterus. If the OH of a secondary alc. is near the aromatic group, the action is a hypertensive one and similar to that of nicotine and curare. The peristalsis is inhibited. If the compd. contains a primary or tertiary OH, or if the secondary is not next to the aromatic group, the arterial pressure is reduced and the peristalsis increased, as in muscarine. A. E. MEYER

**The therapeutic use of esters of cholesterol.** JUAN R. GOYENA AND NICOLÁS A. DÍAZ. *Semana méd.* (Buenos Aires) 35, 813-20(1928).—Cholesterol palmitate and oleate were used with success in pleuritis. A. E. MEYER

**Potassium cyanide poisoning treated with sodium thiosulfate.** JACOBO ZIMMAN. *Semana méd.* (Buenos Aires) 35, 1235(1928).—A child of 18 months, poisoned with KCN, was successfully treated with an intracardial injection of 3 cc. 30% Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln. combined with adrenaline and camphor oil. A. E. MEYER

**The increase of the calcium index in certain pathologic conditions by the use of animalized lime.** JOSÉ E. YGARZÁBAL. *Semana méd.* (Buenos Aires) 35, 1331-32(1928).—The use of citosal is recommended. It is a prepn. of ground oyster shells. A. E. MEYER

**The use of a new iodine preparation (endoiodine) in the treatment of suppurating trichophytosis of beard.** ENRIQUE P. FIDANZA. *Semana méd.* (Buenos Aires) 36, 170-2(1929).—Gram's soln., diluted with saline, produces sclerosis of the veins, after intravenous injection. Endoiodine, a 20% soln. of hexamethyldiaminoisopropyl diiodide, contains 0.18 g. I per cc. The intravenous dose is 2 cc. daily. It is well tolerated and good effects were obtained. A. E. MEYER

**Glucosuria and disturbance of the sugar content of the blood caused by sodium fluoride.** LEON GOLDBERG. *Semana méd.* (Buenos Aires) 36, 1479-81(1929). (In French).—Doses of 0.3 g. of NaF produce in lambs and kids within 2 hrs. after injection a strong glucosuria. 0.5, 1 and 5 mg. per kg. injected in the vein produce in dogs first a decrease, later an increase of the blood sugar. In one expt. in man a decrease of blood sugar was observed after ingestion of 0.1 g. A. E. MEYER

**Continued studies on the influence of parenteral infection and intoxication on the chlorine, calcium and magnesium metabolism.** NILS MALMBERG. *Acta paediatrica* 6, 265-301(1927). E. C. M.

**Pharmacological action of Siliaceae, especially the Allium sativum.** I. Action on the heart. RENZO AGNOLI AND GIUSEPPE LIO. *Arch. intern. pharmacodynam.* 33, 251-66(1927). E. C. M.

**Intoxication by means of several secondary monoamines (methylamine, amylamine, dimethylamine and trimethylamine) as septic poison.** O. KÜNNEMANN. *Deut. tierarztl. Wochschr.* 36, Special no., 79-81. E. C. M.

**The action of nicotine on the vasomotor nervous system.** ITALO SACCHETTO AND HERTHA WITTNE. *Giorn. clin. med.* 8, No. 6, 18 pp(1927). E. C. M.

**Pharmacological investigations of some sympathomimetic amines comparison of adrenalons and tetrahydro- $\beta$ -naphthylamines with adrenaline and tyramine.** MASAO FUJITA. *Okayama-Igakkai-Zasshi* 39, 240-2(1927). E. C. M.

**The effect of surgical solution of chlorinated soda (Dakin solution) in the pericardial cavity.** CLAUDE S. BECK. *Arch. Surgery* 18, 1659-71(1929).—Dakin soln. injected into the pericardial cavity of the normal dog produced pain and tenderness due to erosion of blood vessels immediately when 40 cc. was injected. The end result was pericarditis with effusion or generalized adhesive pericarditis. J. T. M.

**The pharmacology of bismuth salts.** V. Tissue distribution of bismuth. CLIFFORD S. LEONARD. *J. Pharmacol.* 34, 333-46(1928).—In rabbits the av. order of percentage content of Bi in the organs 24 hrs. after intramuscular injection of Na K Bi tartrate was kidney (highest), spleen, adrenals, liver, lung, brain, heart; 24 hrs. after Na Bi citrate, adrenals (highest), spleen, kidney, liver, other organs variable; 3 weeks after di-K Bi tartrate, kidney (highest), liver, spleen, lung. VI. The permeability of the placenta to bismuth. CLIFFORD S. LEONARD AND ROBERT B. LOVE. *Ibid* 347-54.—Pregnant rabbits and cats were given intramuscular injections of di K Bi tartrate and Na Bi tartrate 3-4 days before the expected date of delivery. The animals were killed 48 hrs. after injection. When the dose was  $\frac{1}{3}$  of the lethal dose for the mother the feti and placenta showed no Bi. When the dose was  $\frac{1}{2}$  the lethal dose, Bi could be detected in the placenta but not in the fetus. With doses above the amt. likely to kill in 48 hrs., Bi could be detected in fetal kidneys (large no. bulked together), but not in fetal livers. Hence the placenta is not markedly permeable to Bi. VII. The concentration of bismuth in the blood of dogs after intramuscular injection of bismuth antiluetics. CLIFFORD S. LEONARD AND ALFRED F. SELBERT. *Ibid* 355-64.—Dogs were given intramuscular injections of 40-50 mg. Bi per kg. If the injection was followed by massage at the site of injection Bi appeared in the blood in 2 hrs. after the injection. Without massage Bi was not found in the blood until 24 hrs. later. The Bi concn. remained at a const. level for 2-48 hrs. (0.001 to 0.003 mg. per cc.) and then decreased. Bi usually disappeared

from the blood in 21–30 days. The concn. of Bi in the 24-hr. specimen of urine was always higher than the blood concn. in the same animal. C. RIEGEL

**Clinical and experimental studies on phototherapy in pernicious anemia.** DAVID I. MACHT AND WM. T. ANDERSON, JR. *J. Pharmacol.* **34**, 365–89(1928).—Blood serum from pernicious anemia patients was irradiated by ultra-violet rays of various wave lengths. Its toxicity to the growth of *Lupinus albus* seedlings was detd. Radiation with ultra-violet light decreased the toxicity of the serum, waves of 2967–3660 Å  $\mu$  being most effective. Addn. of certain drugs like eosin which acted as photosensitizers caused a further decrease in toxicity. Polarized light had only slight detoxifying properties. Several patients with pernicious anemia were given ultra-violet ray treatments and their condition was markedly improved, especially if the light treatment were combined with a liver diet. C. RIEGEL

**The action of chlorates, in particular potassium chlorate, on blood in animals.** JOHN L. ULRICH AND VLADIMIR A. SHTERNOV. *J. Pharmacol.* **34**, 391–406(1928).—When  $\text{KClO}_3$ ,  $\text{NaClO}_3$ ,  $\text{Mg}(\text{ClO}_3)_2$ , or  $\text{Ca}(\text{ClO}_3)_2$  was given *per os* or intraperitoneally to cats, dogs, guinea pigs, rabbits and albino rats, the order in which they caused formation of methemoglobin was the reverse of that *in vitro*; i. e.,  $\text{NaClO}_3$  was most active in forming methemoglobin, and  $\text{KClO}_3$  only slightly effective, while  $\text{Mg}(\text{ClO}_3)_2$  and  $\text{Ca}(\text{ClO}_3)_2$  did not cause production of methemoglobin. Destruction of blood corpuscles occurred along with formation of methemoglobin. C. RIEGEL

**The pharmacodynamics and value of bismuth subnitrate in hypertension.** EDWARD J. SIEGELTZ. *J. Pharmacol.* **34**, 407–23(1928) — No parallelism was found between variations in systolic and diastolic pressure and the chloride concn. in blood of normal human beings or of patients with arterial hypertension. Administration of bismuth subnitrate caused a fall in chloride concn. in blood. In pregnancy with hypertension there was improvement under bismuth subnitrate therapy. It is concluded that the beneficial action of bismuth subnitrate in arterial hypertension is due to (1) reduction of chloride ions in blood by diuresis induced by the  $\text{NO}_3$  ion, and (2) gradual vasodilation produced by absorption of small quantities of  $\text{NO}_2$  ions. C. RIEGEL

**Ethylisoamylbarbituric acid (amytal) as a laboratory anesthetic for cats.** MICHAEL G. MULNOS. *J. Pharmacol.* **34**, 425–35(1928).—0.1–0.13 g. per kg. of amytal in 10% soln. in NaOH was given subcutaneously to cats. Anesthetization was complete in 1–2 hrs., recovery in 5 hrs. The blood sugar remained normal and const. for 4 hrs. Disturbance of the animal during anesthesia (as by introduction of a rubber balloon into the stomach through the esophagus) caused a rise in blood sugar. Insulin given during amytal anesthesia reduced the blood sugar. C. RIEGEL

**The uric acid of the blood (investigations on the variations of uric acid in the plasma and in the corpuscles as produced by the action of different substances).** D. LIOUHA. *Arch. farmacol. sper.* **46**, 241–58(1929).—The expts. were conducted on dogs and humans. The uric acid of the plasma and that of the corpuscles were estd. according to Grigaut's method. Insulin, casein, and exts. of the adrenals, hypophysis, corpus luteum and thyroid were administered to dogs on a bread and water diet. With insulin there was an increase in the total uric acid and the plasma uric acid, and a reduction of the uric acid of the corpuscles. Similar results were obtained with thyroid ext. With the other drugs only slight changes were produced, though L. believes he has demonstrated that the pituitary and suprarenal exts. caused a diminution of the total uric acid and an increase of the plasma uric acid. In the expts. with humans, patients were selected in whom the uric acid metabolism was not affected. The patients who did not receive any medicaments that might influence the elimination of uric acid were kept on a purine-free diet for 4–5 days. In 3 diabetics, after administration of insulin, the total and plasma uric acid showed a raise, while the uric acid in the corpuscles was diminished. Casein, pituitary and adrenal ext. had no particular effect. Numerous references are given. G. SCHWOCH

**Acute and chronic poisoning with hyoscyamine and scopolamine.** VITTORIO SUSANNA. *Arch. farmacol. sper.* **46**, 267–74(1929). G. SCHWOCH

**The employment of acetylarsan against spirochetosis in birds.** H. NORMAND. *Arch. Inst. Pasteur Tunis* **17**, 355(1928).—A young cock suffering from spirochetosis recovered completely within 2 days after a single subcutaneous injection of 0.5 cc. of acetylarsan. G. SCHWOCH

**Comparison of the cardiovascular actions of the two stereoisomers, tropanol and pseudotropanol.** MICHEL POLONOVSKI AND RENÉ HAZARD. *Compt. rend.* **188**, 1441–3(1929).—Tropanol is hypotonic and its cardiac action is simply depressive; pseudotropanol is hypertonic and it exerts upon the heart a complex action of the nicotine

type. These differences show the importance of the stereometric position of the aldehyde hydroxyl in the pyrrolidine-piperidine nucleus. G. TOENNIES

Treatment of burns and scalds by tannic acid. W. C. WILSON. *Brit. Med. J.* 1928, II, 91-4; *Pharm. J.* 121, 244(1928). S. W. WALDROTT

Biology of metals. VII. Influence of lead on the development of the chick embryo. FREDERICK S. HAMMETT AND VILMA L. WALLACE. Lankenau Hospital, Philadelphia. *J. Exptl. Med.* 48, 659-65(1928).—The Pb ion has the following effects on the development of the chick embryo: Gross growth is retarded; somite growth is retarded to a degree greater than that exhibited by body length and width, the head and optic analagen are regions of particular sensitivity; their differential development is markedly inhibited. C. J. WEST

The volatile oil contained in the comb of the bumble bee, *Xylocopa circumlans* S. M. RYUZO OBARA. *Folia pharmacol. japon.* 7, 20(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 48, 31.—O. prepd. a volatile oil from this source, which is used as a home-remedy anthelmintic and is very toxic to earthworms. Its action is first paralytic to the motor nervous system and the muscles in which voluntary and reflex movements are prevented. In frogs it causes a central paralysis of the nervous system and a cardiac standstill. In rabbits and cats these symptoms are not caused by proportionately larger oral doses but nephritis and albuminuria develop, the latter even after small doses. R. C. WILSON

Emetine (ANON.) 17. New paths of therapy (HOFMAN) 17. Ureides of brominated derivatives of valeric acid (WEIL, et al.) 10.

## I—ZOOLOGY

R. A. GORTNER

Action of hydrocyanic acid in frogs. V. KARASSIK. *Russ. J. Physiol.* 11, 339-50 (1928).—The arterial color of venous blood of frogs poisoned with HCN becomes darker when the frogs are warmed and reappears on cooling them. There is an increase in the absorption of O by the tissues during the period of warming. B. C. A.

The chemical senses of insects. DWIGHT E. MINNICH. *Quart. Rev. Biol.* 4, 100 (1929).—A review. J. B. BROWN

Respiration of insects. MILTON O. LEE. *Quart. Rev. Biol.* 4, 213-32(1929) —A review. J. B. BROWN

Enzymes and bacteria in the honey bee. F. M. BROWN. *Am. Mus. Novitates* 304, 5(1928); *Exptl. Sta. Record* 59, 562.—B. reports upon examns. made of the flora of the digestive tracts of 72 presumably normal and healthy honeybees. Care must be taken in work on the enzymes of the digestive tracts of insects to exclude those produced by microorganisms present. Normal intracellular enzymes similar to digestive enzymes must be recognized. The normal native enzymes of the digestive system of honeybees are an invertase, both peptic and tryptic proteolytic enzymes, and a lipase. Other carbohydrases may be present under special conditions. One cause of bee dysentery is probably an infection of diastase-producing bacteria. H. L. D.

Lactic acid in fish and crustacean muscle. A. D. RITCHIE. *Brit. J. Exptl. Biol.* 4, 327-32(1927); *Physiol. Abstracts* 13, 572.—Estns. of lactic acid and glycogen in fish and crustacean muscle, where adequate precautions are taken to avoid post mortem change, suggest that the chemistry of such muscular contraction probably resembles that of land-living vertebrates. The low lactic acid values found are in accordance with the small tensions developed, and the more sluggish the nature of the fish the lower are these values. Thus the highest concn. found (haddock 0.26%) is comparable to that found in mammalian heart muscle, the lowest (hake, 0.06%) to that found in reptilian smooth muscle, and is of the same order as that found in the resting abdominal muscle of the lobster. H. L. D.

The relation of *Spirostomum ambiguum* to the hydrogen-ion concentration (alkaline range). P. M. JENKIN. *Brit. J. Exptl. Biol.* 4, 365-77(1927); *Physiol. Abstracts* 13, 562.—At the  $pH$  of its interior, 7.4, *Spirostomum* can survive indefinitely. Increasing alk. decreases the survival time, as estd. by ability to recover when transferred to a normal medium between  $pH$  7.6 and 9.0. Very slight changes in  $pH$  between 7.4 and 7.6 cause considerable and quite disproportionate decreases in the time of survival. Increase in alk. is thought to act because of the increased permeability it sets up in the body wall, causing swelling and eventual bursting. H. L. D.

The lethal action of soluble metallic salts on fishes. K. E. CARPENTER. *Brit. J. Exptl. Biol.* 4, 378-90(1927); *Physiol. Abstracts* 13, 607.—The survival time of fishes

in solns. of salts of Pb, Zn, Fe, Cu, Cd and Hg varies as the logarithm of the reciprocal of the concn., Pb being lethal in a concn. of 1 in 3,000,000. The speed of the reaction depends upon the total quantity of metallic ion present, as well as upon the actual concn., and varies inversely with the size and wt. of the fishes employed. H. L. D.

**Relation of the liver to hyperglucemia in frogs.** J. M. D. OLMSTED AND W. W. SIMPSON. *Univ. Calif. Pub. in Physiol.* 7, 71-2(1929).—Etherization increases the blood sugar 200 to 300% in normal frogs over a period of 3 hrs., but does not increase the blood sugar in frogs from which the liver has been completely removed.

JOSEPH S. HEPBURN

**A method for the preparation of glycogen and a study of the glycogen of the abalone, *Haliotis rufescens*, Swainson.** LOUIS G. PETREE AND CARL L. ALSBERG. *J. Biol. Chem.* 82, 385-95(1929).—The glycogen is extd. from the tissue by 3 extns. with boiling  $H_2O$ , the proteins in the ext. are pptd. with picric acid and the glycogen is pptd. from the protein-free filtrate by alc. It is purified by 4-5 repts. and finally washed with alc. and ether and dried *in vacuo*. Glycogen prepd. by this method from the red abalone contains 0.047% of  $P_2O_5$  which could not be removed by prolonged electrodialysis with ultrafiltration. It could not be obtained free from ash in which were very small quantities of Ca and Fe in addn. to the  $P_2O_5$ . No evidence was obtained that electrodialysis separates unheated glycogen into 2 fractions, one poor in, or free from,  $P_2O_5$  and the other rich in  $P_2O_5$ . No evidence was obtained that abalone glycogen is a mixt. of chem. individuals. During electrodialysis of opalescent glycogen solns., the glycogen sinks to the lower part of the contg. vessel without visible flocculation. A. P. LOTHROP

**A chemical study of Ch'an Su, the dried venom of the Chinese toad, with special reference to the isolation of adrenaline.** H. JENSEN AND K. K. CHEN. *J. Biol. Chem.* 82, 397-401(1929).—The blood-pressure-raising principle of Ch'an Su has been isolated in cryst. form and found to be adrenaline. A report of the study of other chem. constituents will be made later. A. P. LOTHROP

**The influence of varying oxygen tensions upon the rate of oxygen consumption in marine fishes.** F. G. HALL. *Am. J. Physiol.* 88, 212-8(1929).—The scup (an active fish) showed very little variation in  $O_2$  consumption with changes in  $O_2$  tension between 40 and 120 mm. Hg. The puffer (less active fish) showed a change in  $O_2$  consumption with any variation in the  $O_2$  tension of its environmental water up to 100 mm. In the toadfish (sluggish fish) the  $O_2$  consumption varied directly with variations in the  $O_2$  tension between 0 and 118 mm. J. F. LYMAN

**The metabolism of insect metamorphosis.** J. G. H. FREW. *Brit. J. Exptl. Biol.* 6, 205-18(1929).—In the blow-fly during the pupal period the mean R. Q. is 0.65. This can be explained by assuming a partial oxidation of some body substance which never reaches the stage of  $CO_2$  and  $H_2O$ . There is a marked synthesis of glucose during this period. The R. Q. value is too low to account for its complete oxidation, whether it is formed from fat or protein. Since the alc.-ether constituents of the body fail to diminish during the first part of the pupal period, lipides are not the source of glucose. There is no glucose storage in the form of glycogen or other higher carbohydrate in the body of the mature larvae. Although protein must serve as the source of glucose during the earlier part of the pupal period, there is no loss of N by the body. During the latter half of the pupal period the fat content of the body diminishes continuously; this renders possible the conversion of fat to carbohydrate. C. M. McCAY

**Rhythmic susceptibility changes in the cleaving Arbacia eggs.** I. H. PAGE. *Brit. J. Exptl. Biol.* 6, 219-28(1929).—A marked peak of resistance to cytolysis by hypotonic sea water occurs very shortly after fertilization in the sea urchin egg. The same type of resistance phase occurs when saponin is the cytolyzing agent. NaCl and KCl inhibit the production of the resistant phase, while  $CaCl_2$  and  $MgCl_2$  prolong this period. During the resistant phase the eggs swell to a considerably greater extent before cytolysis occurs than at later periods following insemination. Aging reduces the length of the period of cytolytic resistance. C. M. McCAY

**Studies on the intestine of reptiles. II. The acidity of the gastric juice of *Tropidonotus natrix*.** M. VIALLI. *Boll. soc. ital. biol. sper.* 4, 189-91(1929).—The acidity of the gastric juice of *Tropidonotus natrix* is due partly to free HCl. PETER MASUCCI

**The influence of hydrogen-ion concentration on the fertilized and unfertilized eggs of sea urchins.** RIVKA ASHBEL. *Boll. soc. ital. biol. sper.* 4, 239-41(1929).—Fertilized eggs. At  $pH$  4.3 lipid drops sepd. from the cytoplasm and a shrinkage of the cell occurred. On staining with neutral red there was a diminution in coloration from  $pH$  7.5 to 4.3 at which the color disappeared completely. On making the reaction more acid, the coloration reappeared. Unfertilized eggs. No appearance of lipid drops was observed but there was a shrinkage of the cell. The behavior with neutral

red was the same except that the color did not reappear on making the reaction more acid.

**Physico-chemical phenomena during regeneration. II. Measurement of hydrogen-ion concentration in the regenerating limbs of the crab, *Paralithodes camtschatica*.** N. OKUNEV. *Biochem. Z.* **208**, 328-33(1929); cf. C. A. **22**, 4663.—An initial increase in acidity is observed in the region of the regenerating extremity. S. MORGULIS

**The glycogen metabolism of the snail.** MASANORI OKADA. *Okayama J. Med* **40**, 1402-7(1928).—The glycogen content of the snail at the period when it begins to be active after ending its hibernation was: max. 2.39%, min. 0.82%, mean 1.63%. When it is most active (during the rainy season), the max. is 0.81%, min. 0.35%, mean 0.61%. In the period of its hibernation or when it is just entering the hibernation period the max. was found at 7.61%, the min. at 3.52%, mean 4.63%. K. SOMEYA

**Seasonal variation of the glycogen content in the oyster, *Ostrea circumpicta* Pils.** KATSUMI OKAZAKI AND SATARŌ KOBAYASHI. *Science Repts. Tōhoku Imp. Univ.*, 4th Series, **4**, 183-91(1929).—Oysters grown wild were collected from a definite place in Mutsu Bay. The soft body was removed from the shell and was weighed after the body surface was quickly wiped. To prevent the loss of the body fluid, the adductor muscle was dissected out and weighed separately. The samples thus obtained were heated for 10 min. in boiling water to prevent alteration of the glycogen. The heated materials were then dissolved in 60% KOH and the glycogen was detd. by Pflüger's method. The glycogen content varied widely not only with the seasons but with the individuals. A steady increase was shown from Sept. to July, 1 to 4%. Breeding occurred in Aug. at which period the glycogen content reached a min. The glycogen content of the adductor muscle was less than that in the rest of the body. M. H. S.

**Lactic acid and glycogen in the adductor muscles of the oyster, *Ostrea circumpicta* Pils.** SATARŌ KOBAYASHI. *Science Repts. Tōhoku Imp. Univ.*, 4th Series, **4**, 193-205(1929).—The large and small adductor muscles were quickly sepd. from freshly collected oysters. The lactic acid content was detd. by the colorimetric method of Mendel and Goldscheider. There were wide variations in the lactic acid content among the individuals: large adductor muscle 0.0369-0.0810%; small adductor muscle 0.0548-0.1319%. The post-mortem production of lactic acid in the muscles was also detd. With the increase in time after incubation both the large and small adductor muscles showed a steady increase in acid production. The small muscle produced a larger amt. than the large muscle throughout the incubation period. This difference in acid production by the 2 muscles suggests a functional difference. In the muscles fatigued by loading, the lactic acid content of the large adductor muscle was slightly less than that of the small adductor muscle. In the fresh condition the small adductor muscle contained more glycogen than the large adductor muscle. M. H. S.

**The  $p_H$  and carbon dioxide content of the blood, pericardial fluid and the body fluid of the oyster with special reference to their response to the altered condition of sea water.** SEIJI KOKURO. *Science Repts. Tōhoku Imp. Univ.*, 4th Series, **4**, 207-51(1929).—The oyster, *Ostrea circumpicta* Pils., was studied. The pericardial fluid and the blood were carefully withdrawn with a syringe; about 15 cc. of each were obtained from a large oyster. The body fluid was collected after the sea water was carefully removed from the mantle cavity. The  $p_H$  was detd. with the H electrode and the  $CO_2$  was estd. by Van Slyke's method. The normal  $p_H$  values were: blood 7.24, pericardial fluid 7.16 and body fluid 7.11. The  $CO_2$  values were 4.22 vol. % for the blood and 4.00 vol. % for the pericardial fluid. The  $p_H$  of these 2 fluids decreased in early summer and increased in winter. The  $p_H$  of the blood and pericardial fluid of the oyster rapidly decreased when it was subjected to respiration in water of high acidity. The lower limit *in vivo* was  $p_H$  5.40. This decrease of  $p_H$  appeared to be due to the penetration of acid from breathing water into the body. The  $CO_2$  content of the blood and pericardial fluid gradually increased when it respired in the  $H_2O$  of high acidity. The max. limit of this increase *in vivo* was 55.69 vol. %. This increase of  $CO_2$  content was considered to be due partly to the formation of  $Ca(HCO_3)_2$  and partly to the free  $CO_2$  dissolved in the blood and the pericardial fluid. The  $p_H$  of the blood and the pericardial fluid rapidly increased when the animal was submerged in the breathing  $H_2O$  of high alk. The upper limit of this  $p_H$  increase *in vivo* was  $p_H$  8.45. This increase of  $p_H$  was due to the penetration of the OH ion from the breathing water. The  $CO_2$  content of the blood and the pericardial fluid remained unaffected by the increase of blood  $p_H$ . This was probably due to the selective permeability of plasma membrane, which enabled the OH ion alone to permeate, because if Na ion or NaOH mol. penetrated into the blood the  $CO_2$  content must increase, as they will combine with the  $CO_2$  evolved from the tissue. The  $CO_2$  content of the blood and the

pericardial fluid increased and the  $p_H$  of these fluids decreased when the animal was exposed to the atm. air. The former increase was probably due to the formation of  $\text{Ca}(\text{HCO}_3)_2$  in the blood, and the latter decrease to the increase of  $\text{CO}_2$  in the blood. The critical concn. of low blood  $p_H$  which killed the oyster within 48 hrs. was detd. to be in the neighborhood of  $p_H$  5.00. Susceptibility of oyster to high alk. (0.01  $N$   $\text{NaOH}$ ) was greater than to high acidity ( $p_H$  1.20). In the former case the oysters survived for 48 hrs. while in the latter case they usually died within 48 hrs.

M. H. SOULE

**Chemical analysis of the pericardial fluid and the blood of *Ostrea circumpecta* Pils.** MASAO KUMANO. *Science Repts. Tôhoku Imp. Univ.*, 4th Series, 4, 281-4(1929).—The materials were collected during the month of July, 1928. The blood was withdrawn from the heart and usually 8-12 oysters were used for a single detn. The pericardial fluid used was collected from the same oysters. The per cent of  $\text{H}_2\text{O}$  in the pericardial fluid was 96.38, in the blood 96.26. The following table contains the data expressed in g. per 100 cc.

	Pericardial fluid	Blood	Sea water	Method
Na	1.1019	1.1960	1.1634	Michael Balint
K	0.0354	0.0362	0.0357	Kramer and Tisdall
Ca	0.0416	0.0425	0.0431	Kramer and Tisdall
Mg	0.1303	0.1530	0.1373	Hammett and Adams
Cl	1.9520	2.1060	1.9428	Rusznayak
$\text{SO}_3$	0.2673	0.2821	0.2627	Denis

M. H. SOULE

**Some physico-chemical properties of the pericardial fluid and of the blood of the Japanese oyster, *Ostrea circumpecta* Pils, with reference to the change of the external medium.** MASAYASU YAZAKI. *Science Repts. Tôhoku Imp. Univ.*, 4th Series, 4, 285-314 (1929).—Adult healthy oysters were used. The sp. gr. was detd. with the Ostwald modification of the Sprengel pycnometer, the sp. cond. by the Wheatstone bridge method, the f.-p. depression with the Beckmann thermometer, the surface tension with Traube's stalagmometer, the viscosity with Determann's viscometer, and the  $\text{NaCl}$  was detd. by the Rusznayak method. From the large amt. of data presented the following conclusions are drawn: The pericardial fluid is perfectly transparent, while the blood is opalescent with a yellowish tint in transmitted light, and with a bluish tint in reflected light. The quantity of  $\text{NaCl}$  contained in the pericardial fluid is less than that of the blood, and the latter is less than that of the sea water in which the animal lives. The amt. of  $\text{NaCl}$  in the pericardial fluid corresponds to 94 per 100 of osmotic concn. of dry substances, while in the blood it corresponds to 93 per 100. The sp. gr. of the pericardial fluid ranged from 1.022 to 1.024 and that of the blood from 1.023 to 1.028 while the sea water gave from 1.022 to 1.024. These values are affected by the change in the surroundings when the animal is kept in  $1/2$  diluted sea water. The f. p. of the pericardial fluid is about  $0.06^\circ$  higher than that of the blood; this difference corresponds to 0.75 atm. at  $0^\circ$ ; consequently these fluids are not in a state of osmotic equality with each other. When the oysters, which had been kept for a long period in a diluted sea water, were removed into the normal sea water, the sp. gr. and the osmotic pressure of the blood and the pericardial fluid returned to their normal values more rapidly than they were changed by the external conditions when the animals were transferred from the normal to the diluted sea water. These changes were much slower in the pericardial fluid than in the blood. This phenomenon was due probably to the existence of some regulative power in the animal. The product ( $\eta \cdot \kappa$ ) of viscosity and cond. of the blood is nearly const. in the majority of animals of different groups examined, and lies between the narrow limits 0.060 and 0.069. In the blood of the oyster the value of  $\eta \cdot \kappa$  was 0.063 while in the pericardial fluid it was 0.061. The difference in the surface tension between the pericardial fluid and the blood seems due to the difference of protein content rather than to the difference in amt. of  $\text{NaCl}$  in those 2 fluids.

M. H. SOULE

**Normal and abnormal respiration in the oyster, *Ostrea circumpecta* Pils.** AKIRA NOZAWA. *Science Repts. Tôhoku Imp. Univ.*, 4th Series, 4, 315-25(1929).—The respiration of the oyster was detd. under normal conditions and when subjected to a severe strain by hanging a wt. on it. The  $\text{O}_2$  and  $\text{CO}_2$  were estd. by the method of Van Slyke. The gaseous metabolism was accelerated under abnormal conditions. The respiratory quotient at the earlier stage of the oyster on which a heavy load was hung was smaller than that of an oyster without load, but the former suddenly increased

over the latter after some hrs. The metabolism differed at different temps.; the metabolism was diminished at temps. lower and higher than 26°. The rate of O<sub>2</sub> consumption was independent of the O<sub>2</sub> tension until the pressure was reduced to 0.1%.

M. H. SOULE

The digestive enzymes of *Ostrea circumpicta* Pils. EISHIRÔ SAWANO. *Science Repts. Tôhoku Imp. Univ.*, 4th Series, 4, 327-34(1929).—The distribution of amylase and milk-clotting enzyme in the body of the oyster was detd. Butyrase, protease and gelatinase were demonstrated in the crust. style.

Food control in Rotterdam in former times. M. WAGENAAR. *Pharm. Weekblad* 66, 585-93(1929).—Historical.

A. W. DOX

Food protection. W. M. WILLOUGHBY. *Munic. Eng. Sanit. Record* 82, 600 (1928).—H<sub>2</sub>S is formed by the chem. action of SO<sub>2</sub> on Sn when SO<sub>2</sub> is used as a preservative in tinned goods. Synthetic creams made from fats other than milk fat might lead to fraud.

C. H. BADGER

Two outbreaks of food poisoning probably due to *B. cloacae*. ENOS B. BUCHANAN AND EMERSON MEGRAIL. *J. Infectious Diseases* 44, 235-42(1929).

JULIAN H. LEWIS

Study of the neutralization curve and buffer-coefficient curve of some foods (bread, milk, flour). MADELEINE GEX. *Chimie & industrie Special No.*, 698-9(Feb., 1929).

Curves are given for French and English breads, flour and milk. The p<sub>H</sub> value was detd electrometrically by means of 2 Sb electrodes connected differentially, the reference electrode contg. HCl, the p<sub>H</sub> value of which (approx. 1) was accurately detd. It is suggested that this detn. might give valuable information from the standpoint of adulteration and of alimentary hygiene.

A. PAPINEAU-COUTURE

Color of wheat flour. ARTHUR C. HARDY, PRENTISS I. COLE AND CHARLES W. RICKER, JR. *Ind. Eng. Chem., Anal. Ed.* 1, 151-2(1929).—Thirty-five samples of bleached and unbleached flour were examd. by means of a recording color analyzer of improved design. The curve of reflecting power of the samples for different wave lengths of light was obtained. The brilliance score is the reflecting power of the sample at 556 mμ (green). The yellow score is the difference between this and the reflecting power at 440 mμ (blue). The brilliance score decreases with increasing ash content and the yellow score increases.

FRANCIS P. GRIFFITHS

Benzoyl peroxide; its detection in bleached flour. A. LEJEUNE. *Ing. chim* 17, 30-3(1929); cf. Rothenfusser, *C. A.* 19, 1740, 2988.—Jorgensen method; agitate 2.5 g. *p*-diaminodiphenylamine sulfate with 250 cc. of 95% EtOH during 1 hr. Let stand overnight; mix 0.7 g. flour with 2.5 cc. of petroleum ether, add 1 cc. reagent and agitate, on standing, the supernatant liquid has a bluish green color in presence of the peroxide. If the amount is large the flour is also colored. Destree method: put 0.1 g. of *p*-diaminodiphenylamine sulfate in 100 g. of 95% EtOH, heat 30 min. on the steam bath with a reflux condenser, cool. For test put 5 g. of flour in a small flask, add enough reagent to form a paste; after a few min. intense green points appear on the surface. A test can be obtained more than a month after bleaching.

P. THOMASSET

Report of an outbreak of alleged ergot poisoning by rye bread in Manchester. M. T. MORGAN. *J. Hyg.* 29, 51-61(1929).—Some ergotoxin was found in old rye, which would suggest that the fresh rye had been actively toxic.

JOHN T. MYERS

Milk, a biologically balanced food. RAOUL LECOQ. *Bull. sci. pharmacol* 36, 342-4(1929).

A. E. MEYER

The microscopy and chemistry of milk. JAMES SCOTT. *Food Manuf.* 4, 125-7, 195-7(1929).—This is a general survey in which S. briefly discusses color of milk, formation of cream, *Oidium lactis*, lactose, lactic acid and lactic acid bacilli, casein and nuclein, albumin, milk fat and minerals.

J. A. KENNEDY

Rating your milk supply. LEONARD V. PHELPS. *Am. J. Pub. Health* 19, 740-6 (1929).—In the formula for general rating =  $[A + (B + C)/2] + 2$ , A = raw to retail rating, B = raw to plant rating, C = plant process rating and  $(B + C)/2$  = combined rating. A chart for elimination of arithmetical work is given. The federal general rating formula is too inaccurate and misleading to justify a continuance of its use. A general rating should be based, without regard to the % of milk pasteurized, on (a) retail raw score, (b) raw to plant score and (c) plant process score. A general rating should

show the degree with which the community complies with the regulations in the Standard Milk ordinance. J. A. KENNEDY

**Studies of the composition of milk.** O. R. OVERMAN, F. P. SANMANN AND K. E. WRIGHT. Univ. Ill. Agr. Expt. Sta., *Bull.* 325, 174 pp. (1929).—The results of analyses of 1998 milk samples are tabulated, studied by statistical methods and comparisons are made with the results of other investigations into the compn. of milk. The samples were 3-day composites taken at 5-week intervals throughout the lactation periods of individual cows and were distributed as follows: 208 samples of Ayrshire milk, 321 samples of Guernsey milk, 268 samples of Holstein milk, 199 samples of Jersey milk and 1002 samples of milk from Guernsey-Holstein crossbred cows. It should be pointed out that the protein content of milk as detd. from these investigations is higher in relation to the fat content than is usually reported in the literature, and that the lactose does not regularly increase with increasing fat up to a certain fat content and then regularly decrease but that it is nearly const. in % to about 5.0% of fat and then tends to decrease with further increases in fat. Nine tables and 55 figures are included. E. F. SNYDER

**Salts in milk and their importance in dairy work.** The heat coagulation of evaporated milk. H. H. SOMMER. *Butter and Cheese J.* 20, No. 11, 44-8 (1929).—Unless an appreciable acidity has developed, the main factor in the coagulation of milk by heat is the salt compn., particularly Ca and Mg citrates and phosphates. For max. stability toward heat, a proper balance between these anions and cations is necessary. a high albumin content and certain rennet-producing bacteria also make milk coagulate more readily. In most cases of unbalanced salts there is an excess of Ca. This condition can be corrected by the addn. of  $\text{Na}_2\text{HPO}_4$  or Na citrate or by  $\text{NaHCO}_3$  in the milder cases. As a result of several hundred tests it was never found necessary to add more than 0.007% of  $\text{Na}_2\text{HPO}_4$  (calcd. to  $\text{P}_2\text{O}_5$ ) or 0.092% Na citrate (calcd. to citric acid). The amts. of salts used in com. practice are well within the normal variations of these salts in milk. In the rare cases where Ca was in excess in milk, the coagulation was prevented by the addn. of lactic or citric acid. The action of  $\text{NaHCO}_3$  in improving milk contg. excessive Ca is indirect; it is due to transformation of  $\text{NaH}_2\text{PO}_4$  to  $\text{Na}_2\text{HPO}_4$ , thus often correcting an unbalanced salt condition. C. R. FELLERS

**Solubility of metals in milk.** G. N. QUAM. *Ind. Eng. Chem.* 21, 703-4 (1929).—The solubilities of metals in raw whole sweet milk are compared. The solubilities of Al, Sn and steel at 25-70° are negligible. The max. solubilities of Cu, Ni and Zn are obtained at 75-80°. From the standpoint of least soly., special steel (Cr) proved most satisfactory. JOHN T. WOLF

**Nature of iodine compounds in milk.** K. SCHARRER. *Pharm. Monatsh.* 10, 118 (1929).—Except in certain exptl. samples of milk, the conclusion is drawn that the I regularly present in milk is in small part only inorg., the far greater portion being in org. combination with constituents of the serum. The proteins carry a smaller and varying quantity of I. Little or no I is normally carried in the fat. W. O. E.

**Supplementary experiment on the hull substance of milk-fat globules.** K. HATTORI. *J. Pharm. Soc. Japan* 49, 332-6 (1929).—H. previously succeeded in isolating the pure hull substance (I) of milk-fat globules and called it *haptein* (*C. A.* 19, 2380). It is a protein but differs from casein (II) especially in its soly. in dil. NaOH. To support his view the following expt. was made. II was pptd. from fresh milk by various methods, *i. e.*, by AcOH, rennin,  $\text{HgCl}_2 + \text{HCl}$  alum,  $\text{CaCl}_2$ ,  $\text{CuSO}_4$  (Ritthausen's method) and by dialysis. The ppt. was sepd. by centrifugation. By simply mixing the ppt. with  $\text{H}_2\text{O}$  fat globules sepd. from the ppt. On examn. under the ultramicroscope these globules showed a normal shape and were free from the evidence of coagulation. After repeated washing with  $\text{H}_2\text{O}$ , fat was estd. in the washings as well as in the supernatant fluid of the first centrifugate. Except for a sample pptd. with  $\text{CuSO}_4$ , all others gave a quant. yield of fat. If I were composed of II or substances similar to II it would have been impossible to sep. it from the ppt. by simply mixing with  $\text{H}_2\text{O}$ , since the latter substances would undergo irreversible changes. This is addnl. evidence to support the view that I is a different substance from II, which is contrary to the view of others (cf. Titus, *C. A.* 22, 979). NAO UYEI

**Evaporated milk and its relation to public health.** FRANK E. RICE. *Am. J. Pub. Health* 19, 777-83 (1929); cf. *C. A.* 23, 2766. J. A. KENNEDY

**Stability of commercial sterilizers in the presence of milk.** G. N. QUAM AND SIDNEY N. QUAM. *Am. J. Pub. Health* 19, 737-9 (1929).—Data are given to emphasize the fact that NaOCl sterilizers may vary greatly in stability and activity. The conditions under which the sterilizer is to be used, as well as properties of the various com. products, must be considered. Com. sterilizers used were: I. Liquid NaOCl prepn.,

strongly alk. with NaOH. II, NaOCl soln. III, A cryst.  $\text{Na}_3\text{PO}_4\text{-NaOCl}$  prepn. IV, A chloramine-T prepn. In all cases, IV was unusually stable, though a decrease in stability with rise in temp. and extended exposure was noticeable. The order of increasing rate of deterioration of the other 3 was found to be I, II, III. For each sterilizer there was a definite uniform decrease in stability with increase of time for any given temp. The importance of maintaining relatively low temps. during the sterilization of dairy plant equipment seems obvious.

The mold and yeast count as an index of the keeping quality of butter. H. MACY AND H. B. RICHIE. *J. Dairy Sci.* 12, 351-66(1929).

E. H.  
Test for vitamin A in margarine, butter and other fatty foods. A. ANDERSEN AND E. NIGHTINGALE. *J. Soc. Chem. Ind.* 48, 139-40T(1929).—By using a modified  $\text{CHCl}_3\text{-SbCl}_5$  colorimetric test on the unsaponifiable matter in butter, margarine, cod-liver oil and cakes, results closely agreeing with the animal testing method were obtained. The final reading was made by detg. the greatest dilm. at which the blue color was just visible. The av. dilm. figure given by 100 samples of medicinal cod-liver oil was 1950, unsaponifiable matter from cod-liver oil, approx. 1,000,000; butter, 25-60; ordinary vegetable margarine, 0; oleomargarine, trace; Viking vitaminized margarine, 52-62. Several tests on oleo oils showed a vitamin A potency below butter but ahead of vegetable fats and oils. There was no const. relationship between natural color and vitamin A content in oleo oils. In applying the method to cakes, bread, eggs and emulsions, the product is either sapond. directly or the  $\text{Et}_2\text{O}$ -extd. fat is used to obtain the unsapond. portion. An extension of the method to the assay of milk and milk products is in progress.

C. R. FELLERS  
The relation of hydrogen-ion concentration to the texture of Emmenthal or Swiss cheese. PAUL D. WATSON. *J. Dairy Sci.* 12, 289-303(1929).—Variations in the colloidal structure of the cheese, as shown by the difference in the binding of the  $\text{H}_2\text{O}$ , exert an important effect upon the texture. Further work is necessary. The choice of starter is an important factor in the control of the H-ion concn., ripening, and texture of Swiss cheese.

J. A. KENNEDY  
Studies in cereal chemistry. IV. The role of moisture in wheat and flour. T. H. FAIRBROTHER. *Ind. Chemist* 5, 243-5(1929); cf. *C. A.* 23, 3517.—The  $\text{H}_2\text{O}$  content of wheat varies with the locality in which it is grown and the time of year it is used. It detts. the  $\text{H}_2\text{O}$  content of the flour, which in England may be as high as 17%. In flour a high  $\text{H}_2\text{O}$  content promotes growth of mites, bacteria and fungi. In wheat a high  $\text{H}_2\text{O}$  content lowers the bushel weight and increases the respiration and heating. For best results in milling, the  $\text{H}_2\text{O}$  should be concd. in the bran, with the endosperm dry and friable.

AMY LEVESCONTE  
Determination of honey in honey cakes. II. R. T. A. MEES. *Chem. Weekblad* 26, 334-6(1929); cf. *C. A.* 23, 1182.—Baking tests showed that the fructose content of honey cake did not change during the baking, when 55% of the sugar mixt. used was honey. Change of glucose to fructose can take place when the baking powder gives the dough an alk. reaction. For honey cake the % fructose can be accepted to express the amt. of honey used. Sugar was detd. by the method of Schoorl (*C. A.* 23, 2675).

F. DE LEEUW  
Effect of hydrogen-ion concentration on the steam distillation of mixtures of lactic and acetic acids. B. E. LESLEY. *Fruit Products J. and Am. Vinegar Ind.* 8, No. 11, 14-15(1929).—The effect of H-ion concn. on the distn. ratios of acetic and lactic acids was found to be of great importance. A method of steam distn. for the detn. of these acids in their mixtures is presented and its accuracy has been demonstrated. A modification of the Hortvet app. was used.

J. A. KENNEDY  
Sulfuring of sultanas. ARTHUR SKIBBE. *Farming in S. Africa* 3, 1199-1200 (1929).—A method for sulfuring sultana grapes to give a product contg. less than 0.075%  $\text{SO}_2$ , as required by the British regulations, is described. The  $\text{SO}_2$  content of sultanas,

contg. more than 0.075%  $SO_2$ , may be reduced by dipping in water for 2 min. and draining, the process being repeated 3 times during the course of one day, and finally drying in the shade for several days. K. D. JACOB

Factors in the estimation of starch by the I method (LEPIK) 7. The prevention of odor nuisance in the disposal of creamery wastes by treatment with  $Cl$  preliminary to broad irrigation (REINKE) 14. New data on saturnism (KOHN-ABREST) 13. Spray drying and the drying of dairy products (NYROP) 13. Action of  $NaCl$  on hide and animal tissues (PONTE) 29. A chemical study of the rind of California oranges (MATLACK) 11D.

Food. REHMANN & Co. METALLWARENFABRIK. Ger. 477,722, May 24, 1925. A device for sterilizing and preserving food is described.

Preserving foods by coating. I. G. FARBENIND. A.-G. Brit. 302,447, Oct. 17, 1927. Eggs, fruit, etc., are coated with a compn. formed with a condensation product of urea and  $CH_2O$  to which various preservatives, etc., also may be added.

Frozen food products. R. J. ALLNUTT (to Homfreeze Corp.). Brit. 302,883, Dec. 23, 1927. Frozen preps. are formed from agar agar, water and flavoring substances such as fruit juices, fruit acids and sugar.

Food fats. N. V. NEDERLANDSCHE N. V. FRANSCHHOLLANDSCHE OLIEFABRIEKEN NOUVEAUX ÉTABLISSEMENTS CALVEDELFT. Brit. 301,750, Dec. 3, 1927. In order to improve the aroma of products such as margarine or artificial cream, diketones, or substances capable of being transformed into diketones, are added during manuf. The use of diacetyl, and of methylacetylcarbinol and oxidizing agents is described.

Apparatus for sterilizing milk by the "holding" process. R. SELIGMAN. Brit. 302,743, Sept. 29, 1927. Structural features.

Milk filter with conical pre-filter above the main filter pad. KRISTALL-GES. FÜR MOLKEREI-EINRICHTUNG HERM. VOM STEIN M.B.H. Ger. 477,592, July 27, 1926.

Flow regulator for degasifier for milk and cream. PAUL RÜTERS. Ger. 478,003, Mar. 14, 1928.

"Reconstructing" milk, etc. AAGE JENSEN. U. S. 1,721,121, July 16. A fluid mixt. of liquids and normally solid or semi-solid substances is passed between closely spaced elongated surfaces such as a rotating drum and a surrounding casing while subjected to progressive heating. Various details of the app. are described, which may be used for producing products such as margarine emulsions, mayonnaise, fruit emulsions, chocolate and malted milk compns.

Dried milk food. J. GOLDING and DECO, LTD. Brit. 302,439, Oct. 10, 1927. Milk and whey are fed separately but simultaneously on to a heated drying or evapg. surface of the drying-roll type so that they are dried together. Various details of procedure are described.

Treating grain. EFRAÏM RABINOWITSCH. Fr. 657,459, July 12, 1928. Grain is germinated and then fermented under pressure, the pressure being suddenly released to cause the disintegration of the cellular tissue, aleurone and cellulose of the husk to render them digestible in bread made from the treated grain.

Baking powder. C. H. BOEHRINGER SOHN. (Heinrich Schneider and Franz Rahn, inventors). Ger. 478,165, May 31, 1925. See Brit. 252,695 (C. A. 21, 2342).

Phosphorus pentoxide. VICTOR CHEMICAL WORKS. Ger. 477,658, Jan. 23, 1925. A method and app. are described for prepg.  $P_2O_5$  for the manuf. of baking powder, by heating natural phosphates,  $H_2SiO_3$  and C, and oxidizing the P obtained.

Meat-cheese loaf. CLINTON H. PARSONS (to Swift & Co.). U. S. 1,721,406, July 16. A mold is partly filled with a hot cheese emulsion, cooked meat is embedded in the emulsion and the product is sealed in tinfoil while still hot.

Dietary composition containing vitamins and inositol hexaphosphate and its salts. FRITZ GOEDECKE. U. S. 1,721,214, July 16. A compn. which may contain both vitamins and inositol hexaphosphate and its Ca salts is prepd. by use of the same plants as the source of these substances. The compn. may be used as an addn. to chocolate, soups, tea, etc.

Apparatus for heating oleaginous fruits before pressing. KARL SOHLER (to Fried. Krupp Grusonwerk A.-G.). U. S. 1,720,974, July 16. Details are described of an app. with superposed spaced floors and a vertical shaft carrying radial arms with scrapers. Pectin. PECTINERIE DU KERVOR. Brit. 302,734, Dec. 21, 1927. See Fr. 645,993 (C. A. 23, 2225).

Apparatus for aerating beverages. MARCEL MARTIN. Fr. 656,771, Nov. 16,

1927. An app. is described for aerating beverages and treating them with ultra-violet rays.

**Purifying coffee infusions by filtering through active carbon, etc.** J. PÄFFGEN. Brit. 302,332, Dec. 16, 1927. Various details and modifications of procedure and an app. are described. It is stated that caffeine is retained by the filter and may be recovered.

**Food for animals.** J. E. NYROP. Brit. 301,651, Dec. 14, 1927. A milk-like product is prepd. by grinding soy beans, maize or earth nuts with water or skimmed milk and this is emulsified with a fatty or oily substance contg. vitamin A such as deodorized whale oil.

**Animal food formed from ground barley, fish meal and aniseed.** F. R. BELL and R. F. BILTON. Brit. 301,566, Sept. 7, 1927.

### 13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

**American chemical industry, production and foreign trade in the first quarter of the twentieth century.** U. S. Trade Promotion Series No. 78, 114 pp.(1929)

**The handling and packing of chemicals.** REX FURNESS. *Chem. Age* 20, 606-8 (1929).

E H

**Factors in applying spray drying to chemical production.** A. W. FARRALL. *Chem Markets* 25, 59, 61, 63(1929).

E H

**The precipitation of industrial dusts.** M. BELLON. *Ann. hyg. publ. ind. sociale* 1929, 317-40.—A description and discussion of the mech. and elec. methods used in the industries of cement, carbon black, As, Cu, Sn, Hg, Pb, Zn, Ni, etc.

G. TOENNIES

**Technical processes for removing sulfur from gases.** HORST BRÜCKNER. *Metallbörse* 19, 1352-3, 1464-5(1929); cf. C. A. 23, 3560.—A review, with bibliography

W. C. EBAUGH

**The recovery of solvents from enriched wash oil by continuous steam distillation.** OTTO KREBS. *Gummi-Zig.* 43, 1984-6(1929).—A process for recovery of solvent benzene absorbed in wash oil by stripping with steam is described. Steam distn. gives better sepn. of the benzene from the wash oil than does topping by means of a direct-fired still. The cost is low; the fire risk is at a min.

A. WHITE

**Viscous liquid mixed and dried in 80 per cent less time.** R. D. JESSUP. *Chem. Met. Eng.* 36, 413-4(1929).—In the manuf. of a rosin insulating compd. the introduction of circulation of the liquid and application of vacuum to drying reduced the time of operation to  $\frac{1}{5}$  that previously required.

E. H

**Spray drying and the drying of dairy products.** J. E. NYROP. *J. Soc. Chem. Ind* 48, 136-9T(1929).—The several types of driers are described and drying formulas are developed mathematically. High-grade rubber was prepd. by spraying rubber latex in this equipment. Tanning exts., molasses, sugar, fruit juices, blood, cocoa, milk and butter may be dehydrated by this method. CO<sub>2</sub> is the most favorable drying medium for fatty substances because O<sub>2</sub> of the air induces rancidity.

C. R. FELLERS

**Rapid graphical method for calculation of steam distillation problems.** EDWIN M. BAKER AND E. E. PETTIBONE. *Ind. Eng. Chem.* 21, 562-4(1929).—Steam distn. problems are calcd. by using Dühring lines. Graphs are shown using Dühring lines for steam distn. of CS<sub>2</sub>, acetone, chloroform, CCl<sub>4</sub>, benzene, isopropyl iodide, chlorobenzene, aniline and 8 different mixts. of the paraffins occurring in gasoline.

L. A. PRIDGEON

**Technical aspects of slurry filtration.** C. H. SONNTAG. *Pit and Quarry* 18, No. 7, 81-3; No. 8, 46-8, 53(1929).

**Chronic lead intoxication.** ERNST W. BAADER. *Metallwirtschaft* 7, 231-4 (1928).—Lead poisoning is caused mostly by those forms of Pb which are either sol. or upon entering the human body are made sol. Thus Pb and PbO dust in lead around factories cause intoxication while PbS dust in the mines is much less dangerous. Symptoms of Pb intoxication appear sooner when Pb enters the system through the respiratory organs than when it is absorbed from the gastrointestinal tract. A description of the more common symptoms is given. Reference is made to some legal regulations in Germany which aim at the protection of the workers in German Pb industry. E. K.

**New data on saturnism.** E. KOHN-ABREST. *Chimie & industrie Special No.*, 741-2(Feb., 1929).—A case is cited of a young man who, after working some months in a Pb storage battery plant and leaving it in apparently good health, died of saturnism. Analysis of the viscera showed a total of 139.25 mg. Pb, equiv. to 19.5 p. p. m. The Pb contents usually found in human viscera are approx. as follows, in p. p. m.: lungs 2, heart 0.5, liver 2, stomach 3, intestines 1, brain 2, kidneys 2, urine 0.75 and blood 0.5. The following technic is recommended for the toxicological detn. of Pb: destroy org. matter with  $H_2SO_4-HNO_3$ , dil. with 2-3 vols.  $H_2O$ , boil, cool, add an equal vol. of alc., let stand 24 hrs., sep. the ppt. first by decantation and then by alternate washing with alc and centrifuging, evap. the last traces of alc., dissolve the ppt. in 25%  $NH_4OAc$ , pass  $H_2S$ , let stand, centrifuge, wash repeatedly with satd.  $H_2S$ -water, dissolve in hot  $HNO_3$ , evap., verify the presence of Pb by adding KI and identifying  $PbI_2$ , evap. in presence of  $HNO_3$ , dissolve in  $NH_4OAc$  and ppt. the Pb as chromate. Foods generally contain only a few p. p. m. of Pb, at the most; but some white wines have been found to contain up to 5 p. p. m., while the lees can contain up to 15-20 p. p. m. A. P.-C.

Autogenous welding serving the chemical and process industries (JASPER) 9.  
Dependence of resistance of insulating and other materials on potential and frequency (BONING) 4.

**Annual Reports on the Progress of Applied Chemistry, 1928.** Vol. XIII. London: Society of Chem. Industry. 760 pp. 12s. 6d. Reviewed in *Chem. News* 139, 13 (1929)

**Purifying gases.** THE KOPPERS CO. Ger. 478,140, July 27, 1927. See Brit. 280,165 (C. A. 22, 3005).

**Treating gases.** SOC. INTERNATIONALE DES PROCÉDÉS PRUDHOMME-HOUDRY. Fr. 656, 785, Nov. 17, 1927. Reaction vessels contg. contact material acting as absorbents for gases or catalysts for gaseous reactions have annular sections connected at their ends to inlet and outlet pipes and are surrounded both interiorly and exteriorly with a jacket for circulating a heating or cooling liquid.

**Modifying the composition of gas or vapor mixtures.** TH. GOLDSCHMIDT A.-G. Ger. 478,453, June 10, 1921. See Brit. 181,376 (C. A. 16, 3720).

**Treating liquids with gases.** I. G. FARBENIND. A.-G. Fr. 657,203, July 10, 1928. In treating liquids with gases or vapors, the liquids and gases or vapor are introduced simultaneously at the bottom of a vessel contg. indifferent or catalytic material, the liquid flowing off at the top either to another vessel or back to the bottom of the same vessel. Cf. C. A. 23, 2514.

**Separating liquids.** I. G. FARBENIND. A.-G. Fr. 657,442, July 12, 1928. Mixts. of liquids are sepd. by treating them at ordinary or raised temp. with adsorbent agents, e. g.,  $SiO_2$  gel.

**Separating water from slime.** WILHELM LEONARDY. Ger. 477,843, Feb. 24, 1924. The slime is placed in a funnel-shaped vessel with coiled heating tubes and an outlet for clear water at the top.

**Preparation of crystals.** I. G. FARBENIND. A.-G. Fr. 656,642, June 29, 1928. Large crystals, particularly of fertilizing salts, are prepd. by passing a gas or vapor through a soln. of the salt in such a way that the bubbles of gas act as cooling surfaces and cause the continuous formation of germs of crystn., the floating of the growing crystals, the removal of superfluous germs and the circulation of the soln. An app. is described.

**Crystallizing processes.** KARL BAUER and GALICYJSKIE TOWARZYSTWO NAFTOWE "GALICJA" SP. AKC. Austrian 113,327, Jan. 15, 1929. The method of crystg. difficultly crystallizable substances in which a volatile diluent is added to the soln. at a low temp is conducted under superatm. pressure. Examples are given of the crystn. of paraffin from heavy mineral oil and of menthol from peppermint oil. Diluents such as homologs of  $\text{CH}_4$  and  $\text{C}_2\text{H}_4$ ,  $\text{Me}_2\text{O}$ ,  $\text{Et}_2\text{O}$ ,  $\text{Me}_2\text{NH}$  and  $\text{EtNO}$ , may be used, or gases may be passed in, which dissolve in the soln. and reduce its viscosity.

**Method for determining the degree of turbidity of substances by the transmission of light therethrough.** FRIEDRICH HAHN. Ger. 477,640, Apr. 10, 1926. Details are given.

**Drying materials.** MORITZ HIRSCH. Ger. 478,324, Apr. 2, 1926. In drying with hot air, the materials under treatment are rapidly brought to the highest permissible temp. by means of very hot air, and sufficient cooler air is then added to maintain the materials at that temp.

**Recovery of volatile solvents.** I. G. FARBENIND. A.-G. Brit. 302,297, Sept. 12, 1927. Products having a b.p. above  $200^\circ$  obtained as by-products in the catalytic hydrogenation of C oxides to form MeOH are used for washing gases and vapors such as result in the production of lacquers, artificial silk or in cleaning fabrics, e. g., air carrying  $\text{C}_6\text{H}_6$  vapor.

**Dehydration products of sorbitol.** I. G. FARBENIND. A.-G. Brit. 301,635, Dec. 19, 1927. Products which may be used in gelatinizing cellulose esters or ethers or as wetting or emulsifying agents are obtained by dehydrating sorbitol or a mixt. of sorbitol with other polyhydric alcs. (suitably by heating *in vacuo* or in the presence of catalysts such as active silica, C or alumina). Several examples are given.

**Thermal decomposition.** BRITISH DVESTUFFS CORP., LTD. Fr. 657,097, July 6, 1928. Substances are transformed into their decompn. products by heating in a tube, the opening of which is cooled to avoid premature heating of the substance introduced, the remainder being heated, e. g., in a bath of fused salts, or molten Pb.

**Manufacture of substances formed through highly endothermic reactions, particularly nitrogen compounds.** E. CONNERADE. Belg. 356,946, Jan. 31, 1929. In the manuf. of N compds, such as NaCN, cyanamide, Al nitride, etc., the combustible mass is heated to as high a temp. as possible by passing air through it; when this temp. has been reached the admission of air is stopped and N is passed through the incandescent mass.

**Emulsions of oils, etc.** B. REDLICH. Brit. 302,761, Oct. 20, 1927. Emulsions or colloidal suspensions of oils, S, waxes, resins, etc., dissolved in solvents are prepd. by intimately mixing the liquids or dissolved materials with colloidal pptd. inorg. powdery substances such as dried pptd. silicic acid, alumina or ferric oxide and stirring the mixt. into water. Examples are given of a peanut-oil emulsion and an emulsion of S dissolved in  $\text{CS}_2$ . Soap or other protective colloid or stabilizer may be added. Cf. C. A. 23, 1502.

**Purifying air that contains hydrogen sulfide.** ALBERT CHARBONNEAU. Fr. 656,801, Nov. 18, 1927.  $\text{H}_2\text{S}$  in the atm. of artificial silk factories and other places is treated with ozone from ozonizers.

**Storing cesium or similar oxidizable metals in capillary tubes.** W. A. RUGGLES (to British Thomson-Houston Co., Ltd.). Brit. 302,315, Dec. 14, 1927. In sealing readily oxidizable metals such as Cs in capillary tubes, as described in Brit. 296,347 (C. A. 23, 2538), Na Mg borosilicate glass is used so that when the ends of the tubes are fused to seal them the Cs or like metal reacts with the glass at the ends and forms a vitreous material having a coeff. of expansion different from that of the intermediate portions of the tube. This facilitates subsequent removal of the tube ends for liberation of the contents without shattering of the main body of the tube. A method of use with electron discharge devices is described together with various structural features.

**Method of and means for cooling annealed products.** AKT.-GES. BROWN, BOVERI & CIE. Ger. 478,390, Mar. 18, 1927.

**Refrigerators.** LÉO SZILARD. Fr. 657,490, July 13, 1928.

**Refrigerators.** SOC. DES ATELIERS DE CONSTRUCTIONS MÉCANIQUES ESCHER WYSS & CIE. Fr. 656,641, June 29, 1928.

- Refrigerating system suitable for use with liquefied gas such as carbon dioxide.** PETER J. MUENCHEN (to Arctic Refrigeration Mfg. Corp.). U. S. 1,721,312, July 16.
- U. S. 1,721,311 relates to a refrigerating vessel suitable for cooling beverages.
- Absorption refrigerating machine.** GEBRÜDER SULZER A.-G. Ger. 478,339, Dec. 31, 1926.
- Absorption refrigerating machine.** JENS O. BOVING. Ger. 478,336, May 18, 1927.
- Absorbers for absorption refrigerating machines.** GEBRÜDER SULZER A.-G. Ger. 478,337, Feb. 3, 1926 and 478,338, Aug. 25, 1926.
- Refrigerating apparatus of the absorption type.** GUIDO MAIURI and FORTUNATO N. MORASCHI (to Anton E. Anderson and Raoul F. Bossini). U. S. 1,720,603, July 9.
- Structural features.**
- Refrigerating apparatus of the absorption type.** A. J. E. MUTERS. Brit. 301,941, Aug. 2, 1927.
- Refrigerating apparatus of the absorption type.** ELIAS WIRTH-FREY. U. S. 1,720,160, July 9. Structural features.
- Refrigerating system of the absorption type.** H. KEMMER. Brit. 301,837, Dec. 6, 1927. Waste heat from gas plants is used to heat the generator of an absorption refrigerating app. and the refrigerating effect of the app. is utilized to make ice or to cool the gas produced to effect condensation of tar, etc. An arrangement of app. is described.
- Refrigerating apparatus of the compression type.** CLARENCE M. DAVISON (to Poole Engineering and Machine Co.). U. S. 1,720,171, July 9. Structural features.
- Refrigerating apparatus of the compression type.** C. L. HEISLER (to British Thomson-Houston Co., Ltd.). Brit. 301,833, Dec. 6, 1927. Structural features.
- Refrigerating apparatus of the compression type.** HARRY B. HULL (to Frigidaire Corp.). U. S. 1,719,841, July 9. Structural features.
- Refrigerating apparatus of the compression type.** CHARLES L. MCCUEN (to Frigidaire Corp.). U. S. 1,720,797, July 16. Structural features.
- Refrigerating apparatus of the compression type.** C. STENSTRUP (to British Thomson-Houston Co., Ltd.). Brit. 301,746, Dec. 3, 1927. The oil bath of the app. is heated (as by an elec. resistance heater) during the periods when the app. is inactive, in order to prevent collection of condensed refrigerant in the oil.
- Refrigerating apparatus of the compression type.** NORMAN T. WILCOX. U. S. 1,720,310, July 9. Structural features.
- Compression refrigerating machine.** CHICAGO PNEUMATIC TOOL CO. Ger. 478,199, Mar. 4, 1927. Addn. to 473,414 (C. A. 23, 3034).
- Device for deaerating the liquid separated in a compression refrigerating machine.** GEB. SULZER A.-G. Ger. 477,846, Mar. 3, 1927.
- Refrigerating compressor.** MAX GOMPERTZ. Ger. 478,335, Jan. 14, 1927.
- Rotary refrigerating machine.** OTTO HARDING. Ger. 477,775, Apr. 16, 1926.
- Details of the condenser.**
- Cooling the condenser of a rotary refrigerating machine.** AKT.-GES. BROWN BOVERI & CIE. Ger. 477,774, Dec. 7, 1926.
- Insulating electric conductors.** GEORGE L. SCHNABLE (to Western Elec. Co.). U. S. 1,720,749, July 16. Material such as wire is provided with a baked laminated insulation one layer of which is formed from a cellulose deriv. such as cellulose acetate and a synthetic resin such as one formed from a phenol and another layer of which is formed from a solid hydrocarbon material such as ozocerite and a non-drying vegetable oil such as castor oil.
- Electrical insulation with tricresyl phosphate.** WILLIAM F. DOERFLINGER. U. S. 1,721,295, July 16. Tricresyl phosphate is used as a dielectric in transformers, switches, etc.

## 14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

- The Oasis of Farafrah and its springs.** A. AZADIAN. *Bull. inst. Egypte* 10, 49-59 (1929).—Complete mineral analyses of the waters of 29 springs found upon the Oasis of Farafrah showed that all but one (Ain Ghanem) contained good potable water.
- K. S. MARKLEY
- Ain Syra spring.** A. AZADIAN. *Bull. inst. Egypte* 10, 45-8 (1929).—The level of the water of this spring undergoes a marked seasonal variation which results in a

similarly marked variation in its chem. compn. Complete chem. analyses made at 3 month intervals over a period of  $2\frac{1}{2}$  yrs. showed a considerable variation in its content of Mg and Na salts. During the period of low water in the Nile the mineral content of the water of the spring was found to be only half as great as during the high stage. Since the water is not of const. compn. it should not be used as a mineral purgative.

**The Cologne water system and the new water works at Weiler.** E. H. PRENGER. *Gas. u. Wasserfach Special No.*, 31-3(Apr. 19, 1929). K. S. MARKLEY

**Yankton abandons artesian wells for Missouri River.** F. G. BRUECKMANN. *Eng. News-Record* 102, 990-2(1929).—Water obtained from artesian wells had a total hardness of 960 p. p. m., permanent hardness of 830 p. p. m., and Fe content of 2.5 p. p. m., the latter causing widespread staining of plumbing fixtures. To obtain water from the river, intake shafts were constructed in the piers of the Meridian highway bridge; inlet openings were provided at two elevations, just below mean water level and below the stream bed. Single coarse screens were placed in the upper openings and 2 screens with coarse gravel between were provided in the lower openings. If satisfactory water is obtained through the latter the supply will be treated only with  $\text{Cl}_2$ , but if river water from the higher inlets has to be employed provision has been made for construction of a plant for treatment by coagulation and filtration in addn. to chlorination. R. E. T.

**Elimination of red water trouble at Asbury Park, N. J.** STUART K. KNOX. *Eng. News-Record* 102, 1040(1929).—The plant of Asbury Park consisted of 5 deep wells pumped by air lift, 0.2-million gallon settling basin and pressure filters with a nominal capacity of 1.6 million gallons per day, the latter often being operated at twice the rated capacity. The well water is soft and contains 27.5 p. p. m. free  $\text{CO}_2$  and 8.5 p. p. m. Fe. The corrosive nature of the effluent, together with its Fe content, resulted in red water. To correct this condition an aerator consisting of a series of steel pans with alternate perforated and plain sections was installed, timber inlet and outlet flumes were constructed in the basin to eliminate short circuiting and 2 additional 0.5-million gallon per day filters were added. The sand in the old filter units, which had an effective size of 0.92-1.03 mm., was replaced with sand having an effective size of 0.49 mm., and a 25,000-gallon wash water tank was erected so that all the filters could be washed with filtered water. These improvements eliminated the overloading and provided effective filtration.

**Ground and spring water supply of the South Bavarian tertiary region.** LOTHAR REUTER. *Gas u. Wasserfach* 72, 593-602(1929).—A discussion of the geological and hydrological aspects of the ground and spring water in South Bavaria, with mention of mineral water springs and gas and sulfur water wells. R. E. THOMPSON

**The subterranean water resources of Great Britain.** EDGAR MORTON. *Munich. Eng. Sanit. Record* 82, 600(1928).—A brief progress report is made on the mapping of water-bearing formations. R. W. RYAN

**Chemical investigation of subterranean waters.** N. E. KUSHLYANSKII. *Zh. Prikladnoi Khim.* 2, 179-89(1929).—Subterranean waters in the district of Smolensk were investigated. Pollution is at its max. in March and April. Exptl. results showing  $\text{Cl}$ ,  $\text{HNO}_3$ ,  $\text{HNO}_2$  and  $\text{NH}_3$  content of waters over a period of 8 months are tabulated. C. H. BADGER

**Chemical water statistics of German communities.** K. THUMM. *Gas u. Wasserfach* 72, 337-44, 370-3, 404-7, 430-5, 450-5, 470-5, 498-503 and 532-7(1929). The chem. compn. of water of 706 German communities is given. This is also available as a reprint. V. KALICHEVSKY

**Chemical analysis of twelve samples of water collected on an expedition to Sinai.** N. GEORGIADÈS BEY. *Bull. inst. Egypte* 10, 105-14(1929).—Complete chem. analyses were made of the waters obtained from the saline deposits and springs of Moses or Ayun Moussa where according to biblical tradition the Jews were supposed to have ended their flight from Egypt, the oasis of Garandel, Tahib, Ouadi, etc. Some of these waters are potable while others are highly mineralized. R. W. RYAN

**Chemical study of the waters from the wells of the Libyan desert.** N. GEORGIADÈS BEY. *Bull. inst. Egypte* 10, 1-10(1929).—Complete mineral analyses of the waters of a no. of wells in the Libyan desert are presented together with the analysis of saline deposits found in their vicinity. K. S. MARKLEY

**Note on the waters of Ayun Hamman Moussa.** A. AZADIAN. *Bull. inst. Egypte* 10, 11-17(1929).—Analyses show these waters contain a large amt. of  $\text{NaCl}$  and  $\text{CaSO}_4$ . They may be classified as slightly sulfurous but they cannot be compared to the waters of Héluan which contain a high proportion of  $\text{H}_2\text{S}$ . They can be utilized as baths because of their high temp. K. S. MARKLEY

**Tulsa building a 24-m. g. d. water purification plant.** F. M. VEATCH. *Eng. News-Record* 102, 964-6(1929).—A purification plant, at present under construction, and other improvements, are described and illustrated. The settled water will be aerated by compressed air introduced through diffuser plates in the flume connecting Mohawk Lake and the plant, coagulated with lime and alum, filtered through 6 rapid sand filters and finally chlorinated. Interesting features of the plant will include a slotted stilling baffle in the coagulation basin and brass filter underdrain laterals with 2 rows of impact orifices. R. E. THOMPSON

**Water softening plant at Marion, Ohio.** GEORGE WHYSALL. *Munic. News and Water Works* 75, 209-10(1928); *U. S. Pub. Health Eng. Abstracts* E-785c, 46.—Well water is softened by the lime-soda process; the future installation of zeolite softeners is provided for. Details of the treatment are described. The lime reaction is completed before the soda ash is added to the water in the mixing tanks. Alum doses of 0.2 to 0.23 gr. per gal. are added to facilitate coagulation. A Dorr clarifier is used to settle the softened and coagulated water. The turbidity of the effluent of the clarifiers is approx. 2.0 p. p. m. The water can best be carbonated as it enters the clarifying tank and the alum dose is most effective when added at this point. The effluent from the final settling tank following carbonation has an av. turbidity of about 0.5 p. p. m., whereas previously it was as high as 10 to 15 p. p. m. By carbonation the total alk. is decreased from an av. of 55 to 30 p. p. m. and at times to 20 to 25 p. p. m. C. R. FELLERS

**Methods of providing drinking water at coach yards, including study of hydrants, nozzles, connections, etc.** C. M. BARDWELL, et al. *Am. Ry. Eng. Assoc. Proc.* 30, 202-6(1929).—The sanitary handling of supplying drinking water to passenger coaches where through trains are watered is handicapped by lack of time. Better instruction of forces is recommended. R. C. BARDWELL

**Value of a water purification laboratory to a municipality.** NORMAN J. HOWARD. *Contract Record and Eng. Rev.* 43, 735-7(1929).—An outline and discussion of the activities of the Toronto Filtration Plant Laboratories. R. E. THOMPSON

**Hygienic control of water supplies.** BERNHARD BÜRGER. *Gas u. Wasserfach Special No.*, 21-8 (Apr. 19, 1929). R. W. RYAN

**The Provincial Department of Health's relation to the water-works engineer.** A. E. BERRY. *Contract Record and Eng. Rev.* 43, 733-4(1929).—The activities of the Ontario Provincial Dept. of Health in the field of water supply are briefly discussed. Of the 270 water systems in operation in Ontario, 184 are supplied from surface sources and 86 from wells and springs. Seventy-five % of the water used for domestic purposes is chlorinated. The standard requirement for  $\text{Cl}_2$  dosage is a residual of 0.1 to 0.3 p. p. m. free  $\text{Cl}_2$  after 15 min. contact, depending on local conditions. There are now 21 activated sludge plants in operation in Ontario municipalities and 10 in institutions. R. E. T.

**Coöperation produces results in water treatment.** R. E. COUGHLAN. *Ry. Eng. and Maintenance* 25, 158-61(1929).—The water supply used on the 10,215 miles of the Chicago and Northwestern railroad varies from a total dissolved solid content of 3.0 to 209.74 gr. per gal. The first water-softening plant was built in 1904 and 53 are now in service. At other points, a boiler compd. made by company forces is used through a special device attached to the locomotives. A blow off schedule is in effect and a corrosion investigation is under way. R. C. BARDWELL

**Operating aspects of water service.** C. R. KNOWLES. *Ry. Age* 86, 1569-71 (1929).—A general review of Ry. Water Service Activities is given including an est. of 200 billion gallons treated annually at a cost of \$10,000,000. R. C. BARDWELL

**Mechanically cleaned sedimentation tanks for water treatment.** C. T. LEANDER. *Contract Record and Eng. Rev.* 43, 738-41(1929).—There are 30 mechanically cleaned sedimentation basins in operation in United States and Canada. The cost of operation is low,  $\frac{3}{4}$  h. p. being required for a 50-foot unit and 2.78 h. p. for a 200-foot unit. The gentle stirring by the revolving rakes increases the density of the sludge, reducing its water content 5 to 10%. Substantial savings in the cost of chemicals can frequently be effected by preliminary sedimentation of highly turbid water in mechanical clarifiers. R. E. THOMPSON

**Building water stations "out of face."** C. R. KNOWLES. *Ry. Eng. and Maintenance*, 25, 204-8(1929).—The Illinois Central railroad has provided 8 new plants with a total annual capacity of 336,000,000 gal. for new 169-mile line from Edgewood, Ill. to Fulton, Ky. On account of the ground water being limited and of poor quality, reservoirs were required to conserve surface supplies. Standardization was followed, as far as possible, with oil engine power units, centrifugal pumps, pipe lines, and 100,000 gal. capacity creosoted pine storage tanks. R. C. BARDWELL

Watch your water supply's turbidity. J. R. BAYLIS. *Water Works Eng.* 82, 525-6, 550, 553(1929).—A discussion of the significance of and methods for detn. of filter-plant turbidities; of size of particles; of effect on bacteria of turbidity removal; of flocc detectors; of erratic results; and of how Baltimore controls turbidity-measurement standards. E. I. S.

Water consumption varies with standards of living and fluctuations in industrial conditions. ABEL WOLMAN. *Eng. News-Record* 102, 943-8(1929). R. E. T.

Municipal water supplies and the effect of trade wastes in relation to the use of water in power plant practice. V. BERNARD SIEMS, et al. *Fuels and Steam Power (A.S.M.E. Trans.)* 51, No. 12, 87-9(1929).—This is a progress report of Sub-Committee No. 7 on Municipal Water Supply in Relation to Boiler use. There is included a bibliography of 61 titles. E. H.

Control of chlorination of water supplies. ELLIOTT H. PARKS. Ind. State Board of Health, *Mo. Bull.* 32, 35-6(1929); *U. S. Pub. Health Eng. Abstracts E-856a*, 85.—The amt. of Cl used per million gals. of water in Indiana water supplies varies from 2-20 lb. A measurable excess of Cl of 0.1-0.3 p. p. m. in all drinking water is recommended. C. R. FELLERS

Chlorination of waters for industrial use [especially tannery water]. MARTIN AUERBACH. *Cuir tech.* 17, 428-9(1928).—See C. A. 23, 1705. J. G. N.

Chlorine control for a small direct-pressure water system. EARNEST BOYCE. *Eng. News Record* 102, 1042(1929).—For Cl<sub>2</sub> control adopted for a small supply (0.25 m. g. d.) in Kansas obtained from an infiltration gallery and pumped directly into the mains, a small concrete well was constructed which serves both as a mixing tank for the Cl<sub>2</sub> and as a suction well for the centrifugal pump. The water flows from the infiltration gallery into the well at a const. rate, controlled by a fixed orifice with const. but manually controllable head, slightly in excess of the max. pumping rate and an overflow is provided to waste the difference between the inflow and the amt. being pumped into the mains. This arrangement permitted the installations of a relatively less expensive type of chlorination equipment. R. E. THOMPSON

Feeding chlorine through long pipe proves satisfactory. AUGUST V. GRAP. *Eng. News Record* 102, 938(1929).—At the Chain of Rocks plant, St. Louis, Cl<sub>2</sub> is introduced at the point of application of the secondary coagulant at the north end of the filter plant, 800 ft. from the unloading floor. In a room built on the unloading floor 6 batteries of 8 Cl cylinders were connected to manifolds, which in turn were connected to a 3/4-inch galvanized pipe; this conveys the Cl to the chlorinators at the north end of the plant. Liquefaction of the Cl<sub>2</sub> in passing through the pipe gallery, where the temp. is always low, has been eliminated by the installation of a reducing valve in the line in the Cl<sub>2</sub> room and by maintaining a pressure of less than 100 lb. per sq. in. R. E. THOMPSON

Electrolytic chlorine for the destruction of algae. WM. T. BAILEY. *Am. City* 40, 103-5(1929); *U. S. Pub. Health Eng. Abstracts E-846a*, 80.—At Council Bluffs, Ia., the periodic use of CuSO<sub>4</sub> quickly destroyed algae growths in the water supply. Expts indicate that 0.8-1.0 p. p. m. of Cl almost completely stopped the growth of algae in the settling tanks and greatly inhibited their growth in the clear water basins. Electrolytic cells were installed for the manuf. of Cl. The current input of the cells was regulated to produce from 0.5-1.0 p. p. m. of Cl. Cl obtained from the electrolytic cells and com. Cl were compared as to efficiency but no differences were noted providing equal amts. of each were used. C. R. FELLERS

The destructive action on aqueous bacterial suspensions of small doses of chlorine introduced under violent agitation and by means of metallic powders. E. TECHOUEVRES. *Rev. hyg. méd. prév.* 51, 393-425(1929).—As little as 0.1 mg. of Cl added to 1 l. of river water and carefully mixed, either destroys or profoundly alters such bacteria as *B. coli* and *B. typhosum*. This amt. of Cl could not be detected by taste. With *B. typhosum* the Cl acting for 1 hr. on a suspension of 91,800 bacteria per l. destroyed 91.8%. Complete sterilization required from 0.2 to 0.3 mg. of Cl. per l. Thorough mixing was essential for best results. *B. coli* proved somewhat more resistant to Cl than *B. typhosum*. Simple agitation of colon or typhoid bacilli in distd. H<sub>2</sub>O for 6 min. reduced the numbers from 80 to 100%. Metallic Pb, Sn, Cu, Zn, brass and bronze powders (0.01 g. per 100 cc. of distd. H<sub>2</sub>O) were added to *B. coli* suspensions. Although some sterilizing action was effected after several hours exposure, there was only slight immediate effect. Brass powder reduced an original count of *B. coli* of 185 (av.) to 47 immediately after mixing; 211 to 5, after 3 hr.; and 104 to 1 after 24 hr. When bacterial suspensions were filtered over beds of powd. metals, a considerable reduction in nos. of organisms was effected, the rate of destruction being, in general, proportional to the time exposed. C. R. FELLERS

**Corrosive action of water corrected by hydrated lime treatment.** E. SHERMAN CHASE. *Eng. New-Record* 103, 70(1929).—The water supply of Falmouth, Mass., pumped from a natural pond, is practically free of mineral constituents,  $\text{CO}_2$ , Fe and color, supersatd. with dissolved  $\text{O}_2$  and highly corrosive. The water delivered to the consumers was discolored, particularly during the winter months when the consumption was low and the water remained in contact with the pipes for a considerable period. Lab. tests indicated that the corrosiveness could be corrected more efficiently with  $\text{Ca}(\text{OH})_2$  than with  $\text{Na}_2\text{CO}_3$  or  $\text{Na}_2\text{SiO}_3$ . The 83 lb.  $\text{Ca}(\text{OH})_2$  required per million gallons will increase the hardness about 10 p. p. m.

R. E. THOMPSON

**Study and report on incrustation in pipe lines and methods of prevention particularly where treated water is used.** E. M. GRIME, et al. *Am. Ry. Eng. Assoc. Proc.* 30, 154-7(1929).—Softening of water to one gr. per gal. or less will reduce incrustation materially.  $\text{CO}_2$  treatment is not desirable in boiler-water supplies. R. C. B.

**The causes and extent of pitting and corrosion of locomotive boiler tubes and sheets, giving consideration to quality of water, character of metals, methods of manufacture and types of construction.** O. T. REES, et al. *Am. Ry. Eng. Assoc. Proc.* 30, 126-32(1929).—With a review of railroad conditions, the following recommendations are made to reduce pitting and corrosion; use corrosion-resistant material, eliminate defects in manuf., equalize strains by proper design, remove gases from water by feedwater heaters, remove Mg salts from water, reduce H-ion concn., carry excess NaOH in boiler waters, and protect boilers from corrosion during storage.

R. C. BARDWELL

**Control of boiler-water treatment to prevent embrittlement.** FREDERICK G. STRAUB. *Mech. Eng.* 51, 366-7(1929).—Boiler water should be analyzed to find out if the sulfate-alky. ratio conforms to that recommended by the Am. Soc. of Mech. Eng. boiler construction code. If not, it should be treated to prevent embrittlement (cf. C. I. 23, 2231). Either  $\text{Na}_2\text{SO}_4$  in direct proportion to the total alky. or Na phosphate at a definite set figure largely independent of the alky. are most used in boiler water as inhibiting agents. To check the treatment rapid and simple detns. are needed. Alky. is detd. by titrating 100 cc. of the boiler water with 0.19 N  $\text{H}_2\text{SO}_4$ . Turbidimetric detns. of sulfate are more suited to boiler-rooms than the gravimetric detn., but, as the fineness of the ppt. depends upon the manner of its pptn., it must be checked frequently against the gravimetric method. Phosphate is detd. by measuring the vol. of the ppt. of phosphomolybdate in a bulb having a graduated capillary tube, or if inconvenient to heat the solns. is detd. by the following modified colorimetric method. Measure 50 cc. of sample into a 250-cc. volumetric flask with 10 cc.  $\text{H}_2\text{SO}_4$  (3 + 22). Add 5 cc. of molybdic acid soln. (made by dissolving 125 g. pure  $(\text{NH}_4)_2\text{MoO}_4$  without heat in 2000 cc. water, adding slowly 75 cc. concd.  $\text{H}_2\text{SO}_4$  and making to about 2500 cc. vol. with water) followed by 5 cc. hydroquinone soln. (made by dissolving 50 g. pure hydroquinone in about 2500 cc. phosphate-free water to which 3 cc. concd.  $\text{H}_2\text{SO}_4$  is added). After 5 min. 15 cc. of carbonate-sulfite soln. (made by dissolving 1500 g. com. soda ash in 6000 cc. distd. water and adding 225 g. Na sulfite dissolved in 1500 cc. water) is added and the flask made to vol with water. The blue color developed is compared with that formed in standard phosphate solns. prepd. in the same manner. The stock phosphate soln. is made by dissolving in water 0.1432 g.  $\text{KH}_2\text{PO}_4$  dried at  $105^\circ$  for 3 hrs., adding 5 cc. concd.  $\text{H}_2\text{SO}_4$  and making to 1000 cc. 1 cc. = 0.1 mg. phosphate. High Fe content and certain highly colored org. matter interfere with this test. Comparisons must be made in 15 min. after the addn. of the carbonate soln. as the color fades. This method should be checked against the gravimetric detn.

C. H. BADGER

**Combating boiler corrosion.** C. H. KOYL. *Boiler Maker* 29, 164-5(1929).—Presence of NaOH in treated waters has nearly annihilated corrosion of all kinds. Use of soda-ash on hard-water division between Perry, Ia. and Council Bluffs, Ia. has nearly done away with pitting.

E. I. S.

**Cost of impurities in locomotive water; report on methods of water treatment where complete lime and soda-ash treating plants cannot be justified or pending their construction.** C. H. KOYL, et al. *Am. Ry. Eng. Assoc. Proc.* 30, 133-8(1929).—Soda ash, Na aluminate and proprietary compds. are recommended. R. C. B.

**Cost of impurities in locomotive water; review progress in water treatment on railroads and report on possible future development.** C. H. KOYL, et al. *Am. Ry. Eng. Assoc. Proc.* 30, 139-42(1929).

R. C. BARDWELL

**Biochemical oxygen demand of certain substances.** G. E. SYMONS WITH A. M. BUSWELL. *Ind. Eng. Chem., Anal. Ed.* 1, 161-2(1929).—Using the diln. method for detg. biochem. O demand, the O demands of pure substances such as starch, urea, Na palmitate, lactose, cellulose and peptone were detd. Compds. contg. both C and N show two-stage oxidation.

A. L. ELDER

**Report on the use of gravity and pressure filters.** D. A. STEEL, *et al.* *Am. Ry. Eng. Assoc. Proc.* **30**, 158-70(1929).—A survey indicates that only a small percent of railway water supplies are equipped with filters. A rapid gravity type is preferred. A general description outlining fundamental principles is given. R. C. BARDWELL.

**Active charcoal filter for improving taste of potable water.** IMHOFF AND SIERP. *Gas. u. Wasserfach* **72**, 465-6(1929).—Chlorophenols, algae and mineral substances giving a bad taste to drinking water may be removed by passing the previously purified and chlorinated water over an active charcoal filter. The resultant filtrate is free from taste. A plant for treating about 25,000 cu. m. of water daily cost 20,000 M. R. W. RYAN.

**Rapid sand filtration plants. Important factors to be considered in designing modern plants.** T. C. HERSEY. *Water and Water Eng.* **31**, 227-9(1929).—See C. 1 23, 2516. J. A. KENNEDY.

**Specifications for filter sand and gravel.** ANON. *Am. City* **40**, 92-3(1929).—Filter sands and gravels are discussed with respect to their use in water filtration plants and sewage treatment works. The effective size and chem. compn. are presented in tables. C. R. FELLERS.

**Coal and sand as filter media.** O. J. RIPPLE. *Water Works Eng.* **82**, 327 & 358(1929).—R. describes Denver water-works expts. designed to det. the advantages in combination of sand and anthracite coal as filter material and proper proportions of each. E. I. S.

**Observations on ice.** P. BALAVOINE. *Mitt. Lebensm. Hyg.* **20**, 77-8(1929).—The cloudiness in the center of blocks of artificial ice is only partly due to the gas dissolved in the water. It may also be caused by the mineral matter in hard water putg out, during the freezing process, as shown by the presence of a ppt. in the melted ice, and to droplets of satd. solns. of these salts. When ice is to be analyzed it should be melted in a closed vessel, since in melting it tends to absorb  $\text{NH}_3$  from the air. This fact may explain the presence of  $\text{NH}_3$  in cistern water obtained from melted snow.

**Modern Venturi water meters.** G. EGGERS. *Gas u. Wasserfach Special No.*, 43-53(Apr. 19, 1929).—Discussion, with diagrams and many illustrations of German types. R. W. RYAN.

**Recent advances in public health bacteriology.** W. T. WILSON. *Munic. Eng. Sanit. Record* **82**, 600(1928).—The great majority of typhoid "carriers" are non-infective. C. H. BADGER.

**How Lunéville eliminated typhoid fever.** DELORME. *L'eau* **22**, 51-4(1929).—Since the javellization of the city water supply from the River Meurthe in 1914, the typhoid and paratyphoid fell from an annual av. of 23 cases to less than 1 case per year. C. R. FELLERS.

**Typhoid fever in the large cities of the United States in 1928.** ANON. *J. Am. Med. Assoc.* **92**, 1674-6(1929); *J. Am. Water Works Assoc.* **21**, 963-74. E. H.

**The intestinal bacteria of fishes from the standpoint of the hygienic estimation of drinking water.** I. E. MINKEVICH AND N. A. TROFIMNK. *Z. Hyg.* **109**, 39(1928), *U. S. Pub. Health Eng. Abstracts E-840a*, 78.—Coliform bacteria in the intestines of fish were cultured on 2% glucose peptone soln. and incubated at 46°. Gas formation in this medium, in a majority of cases, indicates the presence of *B. coli* of animal or human origin. The intestinal tracts of fish are inimical to the growth of genuine *B. coli* from warm-blooded sources, even when the fish are taken from polluted waters. C. R. F.

**Water and sewage control for state institutions.** GEORGE L. HALL AND W. W. BLOHM. *Eng. News-Record* **103**, 52(1929).—A plan developed in Maryland for supervision of water and sewage works at state institutions is described. Results obtained to date at 4 of the 9 state institutions have been encouraging. R. E. THOMPSON.

**The Kew experimental sewage-treatment plant.** H. A. WOOD. *Australian Munic. J.*, 1929, 398-403; *U. S. Pub. Health Eng. Abstracts E-840b*, 66.—The Kew plant consists of a 2-story tank, filter bed, humus tank and sludge beds. The per capita flow is 23 imp. gal. per day. The raw sewage contained 1680 p. p. m. total solids and 920 p. p. m. suspended solids. The treatment reduced the suspended solids 90% and the  $\text{O}_2$  consumed at least 95%. C. R. FELLERS.

**The efficiency of settling tanks in sewage-treatment plants.** M. B. TARK. *Am. City*, **40**, 99-100(1929); *U. S. Pub. Health Eng. Abstracts E-856*, 72; *cf. C. A.* **23**, 3040.—Essential features in the design of sedimentation tanks are (1) means for decreasing the velocity of flow, (2) provision of a zone of quietness for the accumulation of solids and (3) means of removing the accumulated solids. Rectangular vertical-flow tanks give a higher % removal than horizontal-flow tanks. The speed of the sludge removal mech-

anism should be as low as possible, and not in excess of 3-5 ft. per min. Intermittent operation once a day in cool weather and twice a day in warm weather gives best results.

C. R. FELLERS

**Sewage purification with special attention to gas recovery.** BLECH. *Gas u. Wasserfach* 72, 579-84(1929).—Methods of removing solids from sewage are reviewed and compared, with special attention to the methods (Emscher, etc.) involving fermentation of the sludge with gas recovery. Results of an exptl. plant at Waldenburg are presented which indicate that it is desirable to heat the fermentation chamber in cold weather to secure max. gas production, as this occurs (at Waldenburg) at 32°. The rate of gas evolution over a period of 2 months is shown graphically. Sufficient gas should be produced to supply all heat and power requirements for the disposal plant and leave an excess for sale.

R. W. RYAN

**Sewage material and various treatment processes for its removal.** PRÜSS. *Gesundh. Ing.* 52, 246-8(1929).—Of the total sewage material, about  $\frac{3}{4}$  is insol. and  $\frac{1}{4}$  is sol. Two-thirds of the insol. sewage material will settle and  $\frac{1}{3}$  will not. The insol. sewage material consists of 30% mineral matter and 70% org. matter. One-fourth of the total sewage material is org. and is about  $\frac{1}{3}$  colloidal and  $\frac{2}{3}$  crystalloidal. Mech. sludge removal will remove about 95% of the insol. sewage material. Biol. treatment in conjunction with mech. sludge removal will remove all but 5% of the total sewage material.

WAYNE L. DENMAN

**Sludge digestion.** C. G. GILLESPIE. *Calif. Sewage Works J.* 1, 75-86(1928); *U. S. Pub. Health Eng. Abstracts E-840*, 69.—If digestion is too prolonged, decompn. accompanied by offensive odors occurs. A properly functioning tank must maintain a balance of approx. 50 times the amt. of ripe sludge (dry basis) as raw sludge. In Calif. most tanks are operated at too low a sludge level, i. e., the tanks contain only semi-digested and raw sludge. Agitation materially reduces the time of digestion. CaO proved very useful in neutralizing raw sludge acidity and thus accelerating digestion.

C. R. FELLERS

**The associations opportunity for promoting railway sanitation.** H. W. VAN HOVEN-BERG. *Am. Ry. Eng. Assoc. Proc.* 30, 207-9(1929).—Possible saving to be effected warrants study and standardization of items involving railway sanitation.

R. C. B.

**Kentucky swimming-pool regulations.** KENTUCKY STATE BOARD OF HEALTH. *J. Am. Assoc. for Promoting Hyg. and Pub. Baths* 10, 68-9(1928); *U. S. Pub. Health Eng. Abstracts E-840a*, 7.—Excess Cl limits shall be 0.2 to 0.5 p. p. m. when Cl compds. are used. When alum is used water shall test alk. Water shall be clear enough to show a 6-in. disk at the deepest pt. from a distance of 10 yds. Water should not be heated to over 22°. 2°.

C. R. FELLERS

**River pollution and its effects.** J. H. COSTE. *Munic. Eng. Sanit. Record* 82, 600(1928).—A brief discussion on the careful treatment and protection given to the water supply of London, England by authorities.

C. H. BADGER

**The prevention of odor nuisance in the disposal of creamery wastes by treatment with chlorine preliminary to broad irrigation.** E. A. REINKE. *Calif. Sewage Works J.* 1, 128-32(1928); *U. S. Pub. Health Eng. Abstracts E-840b*, 61.—Chlorination of fresh creamery wastes followed by irrigation at Waco, Calif., effectively controlled the odors in creamery waste disposal. The chlorinator was set up at the creamery discharging directly into the sewer. The wastes were about 1 hr. old when they reached the 15 $\frac{1}{2}$  acre irrigation farm. Approx. 125,000 gal. of waste was handled daily. A Cl dose of 20 p. p. m. was the min. required to control odor. Over-chlorination produced offensive chem. or medicinal odors at times. The total cost of disposal (av. 3 months) was 0.096¢ per gal.

C. R. FELLERS

**Treatment of paper-mill wastes.** ABEL WOLMAN. *Munic. News and Water Works* 76, 131(1929); *U. S. Pub. Health Eng. Abstracts E-856*, 72.—The waste treatment of the large plant of the Congoleum-Navin Co. is discussed. A treatment of 90 grains per gal. of CaO and 50 grains per gal. of alum, produced an effluent approx. equal to that obtained with alum at the rate of 140-180 grains per gal.

C. R. FELLERS

**The toxicity to animals of alkaline effluents.** L. HUGOUNENG, A. MOREL AND A. JUNG. *Ann. hyg. publ. ind. sociale* 6, 43-9(1928); *Bull. Hyg.* 3, 754(1928).—Alkali effluents emptied into the river at low stage killed fish and caused diarrhea in animals which drank it. Analysis showed 0.04 g. of NaOH and 0.212 g. of NaHCO<sub>3</sub> per l. Small quantities of Sn, Pb and Na were present. A soln. of less strength caused diarrhea and wasting for several days.

SWINSON, E. THOMAS: *The Sanitation of Buildings*. New York: Oxford Univ Press, Am. Branch. 465 pp. \$10.

**Apparatus for filtering water and treating it with emanations from radioactive material.** F. L. MAIN. Brit. 302,095, March 19, 1928. An app. is described having a sand and charcoal filter and contg. a receptacle which may be charged with ore contg. carnotite.

**Open-tank filter.** A. C. HANDLEY. Brit. 302,446, Oct. 15, 1927. A filter is described suitable for treating sewage and "trade effluents" and which may contain coir fiber and sand.

**Apparatus for softening water by treatment with zeolites.** ANDREW J. DOTTERWEICH. U. S. 1,721,105, July 16. Structural features.

**Apparatus for softening water with zeolites and regenerating the used material.** CLIFFORD F. SMITH. U. S. 1,719,908, July 9. Structural features.

**Apparatus for softening water with base-exchange substances.** UNITED WATER SOFTENERS, LTD., and H. S. LAWRENCE. Brit. 302,744, Sept. 29, 1927. Salt for regenerating the water-softening material is formed into a sludge or scurry and drawn into the app. by use of an ejector. Various structural details are described.

**Base-exchange silicate.** ROBERT O. FRIEND and EDWIN M. PARTRIDGE (to Permutit Co.). U. S. 1,720,074, July 9. A batch of greensand is treated with Na silicate, washed thoroughly, and Al sulfate is then added to the batch in a quantity greater than can be neutralized by the remaining Na silicate, so as to impart an acid character to the soln. Cf. C. A. 22, 4694.

**Base-exchanging silicates.** A. ROSENHEIM. Brit. 302,690, Dec. 20, 1927. Silicates such as glauconite or artificial alkali Al silicates are stabilized and have their base-exchanging capacity increased by treatment first with acid-reacting aq. solns. of salts of metals which are at least divalent and then with aq. solns. of neutral alkali metal salts such as NaCl. Salts of Fe, Mn, Al, Cr, Ni, Cu, Zr, Zn, Sn or Ti may be used in the first stage of the treatment. Various examples are given.

**Treating boiler-feed water.** PHILIPP SCHENITZA. Ger. 478,450, Jan. 30, 1925. A compn. to be added to the water for preventing and removing incrustation comprises a resin, gum, borax and waterglass, suitably in the relative proportions 60, 20, 10 and 10, resp.

**Distilling boiler-feed water.** NAAMLOOZE VENNOOTSCHAP NECKAR WATERREINIGER MAAATSCHAPPIJ and H. NOORDENDORP. Brit. 301,666, Jan. 10, 1928. Steam obtained by expanding the sludgy water from a boiler is used to evaporate the make-up feed water for the boiler. An arrangement of app. is described.

**Incrustation preventive and remover for use in boilers.** JOHN H. OBERHOLTZER (one-half to Robert C. Murphy). U. S. 1,720,565, July 9. Starch (0.5-5.0 lb.) is used with a soln. of 1-5 lb. alkali meta hydroxide in 20-100 gals. water in which 0.5-5.0 bu. of decayed wood have been digested.

**Distributing liquids on filter beds, cooling ponds, etc.** J. FORD. Brit. 302,817, Jan. 11, 1928. Mech. features.

**Biological purification of household refuse based on the principle of cesspools with colloidizers and nitrifying filters.** M. VAN ACKER. Belg. 355,669, Dec. 31, 1928. An app. is specified.

## 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

**Determination of total replaceable bases in soils.** R. H. BRAY AND F. M. WILHITE. *Ind. Eng. Chem., Anal. Ed.* 1, 144(1929); cf. *C. A.* 23, 462.—When the filtrate from a soil leached with a neutral  $\text{NH}_4$  acetate soln. was taken to dryness, carbonates of the replaceable bases were formed as a result of heating the acetates. This suggested the idea of detg. the total amt. of replaceable bases by titrating the carbonates or oxides thus formed.

E. F. SNYDER

**The hydrometer method for studying soils.** B. A. KEEN. *Soil Sci.* 26, 261-3 (1928).—Factors involved in the hydrometer method (*C. A.* 22, 292) for studying soils are given. The results show differences in hydrometer readings between top and bottom halves of the same suspension of between 10 and 30%, depending on the soil and the time of standing.

M. S. ANDERSON

**The microscopic method of studying bacteria in soil.** H. J. CONN. *Soil Sci.* 26, 257-9(1928).—An improved technic is described for staining bacteria in soils. The presence of a minute trace of a Ca salt decreases the soly. of the dye and improves staining power.

M. S. ANDERSON

**The hydrogen peroxide-hydrochloric acid treatment of soils as a method of dispersion in mechanical analysis.** G. B. BODMAN. *Soil Sci.* 26, 459-70(1928).—A comparison was made of the  $\text{H}_2\text{O}_2$ -HCl method and rubbing in dil.  $\text{NH}_4\text{OH}$  as a means of dispersion of 5 soils. A much higher degree of dispersion was obtained for a highly org. soil and for a calcareous one when the  $\text{H}_2\text{O}_2$ -HCl treatment was used. For a hardpan soil the  $\text{H}_2\text{O}_2$ -HCl treatment was entirely inadequate, and rubbing with  $\text{NH}_4\text{OH}$  was much more effective. A "black alkali" soil and a highly ferruginous clay soil were equally well dispersed by both methods. The advisability of treating Ca-satd. soils with  $\text{H}_2\text{O}_2$  and HCl is questioned. Comparisons made between the pipet-sedimentation method and the indirect  $\text{H}_2\text{O}$  vapor adsorption method for detn. of colloidal content of soils showed higher results by the latter method in each case. Black alkali soil showed excessively high results by the  $\text{H}_2\text{O}$  adsorption method.

M. S. ANDERSON

**Retention of phosphate by hydrated alumina and its bearing on phosphate in the soil solution.** LEWIS B. MILLER. *Soil Sci.* 26, 435-9(1928).—The extent to which the  $\text{PO}_4$  ion is carried down by pptg. alumina at different H-ion concns. was detd. in the following manner: 0.02 M  $\text{AlCl}_3$  contg. an equiv. quantity of  $\text{KH}_2\text{PO}_4$  was treated with varying quantities of NaOH in a total vol. of 500 cc. The  $p_H$  was detd. colorimetrically in the supernatant liquid after settling. The ppt. was washed and analyzed. From the  $p_H$  value at which pptn. begins up to a  $p_H$  value of 4.5 the mol. ratio of  $\text{Al}_2\text{O}_3$  to  $\text{P}_2\text{O}_5$  is 1:1; that is, the ppt. has the compn.  $\text{AlPO}_4$ . At higher  $p_H$  values the  $\text{PO}_4$  content of the ppt. rapidly decreases. The H-ion concn. at which the  $\text{PO}_4$  content of the ppt. becomes zero is not realized, since the ppts. formed at the higher  $p_H$  values are extremely colloidal and difficult to study. The indications are, however, that the  $p_H$  values above 8.5 the  $\text{PO}_4$  becomes small. It is thought permissible to apply these results to some extent to the hydrated  $\text{Al}_2\text{O}_3$  and  $\text{Fe}_2\text{O}_3$  of the soil colloids.

M. S. ANDERSON

**The effect of different proportions of calcium nitrate and potassium dihydrogen phosphate on the growth of wheat in sand cultures.** DUKE D. BROWN. *Soil Sci.* 26, 441-6(1928).—A high ratio of  $\text{Ca}(\text{NO}_3)_2$  to  $\text{KH}_2\text{PO}_4$  increased tillering and caused heavy succulent growth. High  $\text{KH}_2\text{PO}_4$  produced the heaviest root growth. Ca, K, P and S were absorbed in proportion to the concns. of these elements in soln. An increase of K decreased absorption of Mg. Fe and Al were practically const. in the ash of all plants. High Ca slightly inhibited absorption of  $\text{NO}_3$  ion. Total ash was high in all expts. but was highest in those showing chlorosis. Apparently growth abnormalities and low yields were due to the unusually high absorption of mineral elements from soln.

M. S. ANDERSON

**The ratio of sulfur to phosphorus in western Oregon soils and losses of sulfur through drainage and cropping.** J. S. JONES. *Soil Sci.* 26, 447-53(1928).—Chem. analyses of Oregon soils show wide variation in their content of S and P as well as ratio of S to P. The P content of a variety of crops grown in this region shows a slightly wider variation in P than in S. It is thought that no particular ratio of these two elements is indicative of optimum conditions from the standpoint of soil fertility. Absolute amts. of each element are, however, considered of first importance.

M. S. ANDERSON

**Exchangeable cations in soils as determined by means of normal ammonium chloride and electrodialysis.** BENJAMIN D. WILSON. *Soil Sci.* 26, 407-21(1928).—The exchangeable bases of 12 soils were studied by means of extn. with  $N \text{ NH}_4\text{Cl}$  and

by electro dialysis. Soils of different types varied widely as to quantity of cations extd. The quantity of cations present was to some extent an index of the fertility of the soils. The quantities of Ca replaced by  $NH_4Cl$  and by electro dialysis were in close agreement. Larger quantities of Mg and in some cases more K was extd. by  $NH_4Cl$  than by electro dialysis. When electro dialyzed soils were treated with  $NH_4Cl$  considerable Al was liberated, signifying a partial decompn. of the aluminosilicic complex. Titration of diffusates was found to be a more satisfactory measure of the cation content than detn. of  $NH_4$  adsorbed from  $NH_4Cl$ . Electro dialyzed soil when freed from sol. anions approached a reaction value of  $pH$  4.0. Cations extd. by  $NH_4Cl$  may include certain cations not held in the adsorbing complex of the soil, and hence, not exchangeable cations, as the term is usually employed.

**Crop response to lime on acid soils.** R. E. STEPHENSON. *Soil Sci.* 26, 423-34 (1928).—The exchangeable Ca of acid Oregon soils is much higher at the surface than in lower horizons. The soils appear to be inherently deficient in Ca as shown by the low exchangeable Ca and the high acidity of the parent soil-forming material  $CaCO_3$  treatments significantly increase the  $pH$  at the surface but the effect on the subsoil is very slight. There is a marked crop response to liming.

**Colloids and soil fertility.** A. DEMOLON. *Ann. sci. agron.* 46, 46-66(1929) — See C. A. 23, 1198.

**Lime, potash and alfalfa on Piedmont soils.** R. P. BLEDSOE. *J. Am. Soc. Agron.* 21, 792(1929).—It appears that rust or  $K_2O$  hunger in cotton following alfalfa is caused by the lime which is always applied for alfalfa in this section (South Carolina). The old idea that lime liberates  $K_2O$  does not seem to be true on these soils. Either the lime locks up the  $K_2O$ , so that the cotton plant cannot get it, or the lime greatly increases the need of cotton for this element.

**Rapid microchemical determination of potassium in soils and vegetation.** IDA LONSTEIN. *J. S. African Chem. Inst.* 10, No. 2, 27-31(1927).—Use is made of the cobaltinitrite method for detg. small quantities of  $K_2O$  in soils and vegetation. The general method, precautions, accuracy of the method, method for vegetation and soils and the time factor are discussed.

**Method for comparing the value of ammonia, nitrogen and nitrate nitrogen.** WM. G. FRIEDEMANN. *Science* 70, 43-4(1929).—The dry weight of cotton plants grown in solns. contg. (a)  $NH_3$  as a source of N and (b) nitrate as a source of N was used as a basis for comparing the nutrient value of these 2 sources of N. Except for the above difference the nutrient solns. were practically identical in chem. compn. They were buffered at a  $pH$  of 5.8; the osmotic pressure was approx. 1 atm. The  $pH$  was maintained const. upon the roots by mech. stirring by aeration and by const. soln. renewal at a rate of flow of 1.4 cc. per min. per plant. The plants were harvested and their dry weights detd. at the age of 6 weeks. Comparative values were thus obtained.

**Determination of phosphoric acid in mineral phosphates and phosphate fertilizers.** GUNNER JORGENSEN. *Ann. fals.* 22, 199-207(1929); cf. C. A. 19, 2613; 20, 1773. The technic of J.'s method for the detn. of total  $P_2O_5$  in mineral phosphates, total  $H_2O$ -sol. and citrate-sol.  $P_2O_5$  in superphosphates, and total and citric-sol.  $P_2O_5$  in basic slags is described in detail.

**Influence of mineral fertilizers on the osmotic pressure of some agricultural plants and the special action of potassic fertilizers.** E. BLANCHARD AND J. CHAUSSIN. *Compt. rend. acad. agr. France* 15, 678-82; *Compt. rend.* 188, 1515-7(1929).—The application of mineral fertilizers in increasing the rapidity of growth and the yields acts certainly, apart from the contribution of the plastic elements, by physico-chem. action, in increasing the osmotic pressure. An important part of this action is due to the potassic fertilizers, in sylvite and KCl.

**The use of additional nitrogenous fertilizers on autumn wheat.** F. PARISOT AND E. GIRARD. *Compt. rend. acad. agr. France* 15, 700-3(1929).—The time of fertilizer application and yields are discussed.

**Fertilizer ratios for Prince George County.** A. G. MCCALL. *Maryland Sta. Bull.* 294, 35-51(1928).—A study of the effect of different fertilizer ratios on some of the more important soil types of Prince George County. The fertilizers used were com. grades of  $NaNO_3$ , acid phosphate and KCl and the soil types included Leonardtown Silt Loam and Loam, Collington Sandy Loam, Norfolk Sand and Sassafas Loam. The crop yields on the different soil types and the fertilizer ratios are given.

**History and technic of the superphosphate industry.** ANON. *Superphosphate* 2, 133-6(1929); cf. C. A. 23, 3769.

**Sewage sludge as fertilizer.** WILLEM RUDOLFS. *Soil Sci.* 26, 455-8(1928).—The N content of sewage sludges varies with the type of treatment. Aerobically treated sludge contains about 5.0% N, while anaerobically treated sludge averages about 2.25% N. It is estd. that 150,000 to 200,000 tons of N is lost annually in this material, much of which might be saved for fertilizer. M. S. ANDERSON

**Chemical notes.** Manurial value of dadaps and gliricidia leaves, stems and branches. A. W. R. JOACHIM. *Trop. Agr. (Ceylon)* 71, 7-8(1928).—Fresh leaves and tender stems of dadaps and gliricidia contain  $H_2O$  69.8 and 73.1, N 1.09 and 0.79,  $CaO$  0.58 and 0.77,  $K_2O$  0.34 and 0.37,  $P_2O_5$  0.14 and 0.19 and ash 1.84 and 2.58%, resp. A. L. MEHRING

**The influence of fertilization with iodine on the growth and composition of food plants.** E. MAURER, W. SCHROPP AND H. DUCKRUE. *Münch. med. Wochschr.* 75, 1246-7(1928).—Fertilization with KI (2.5 kg. per hectare) caused an increase in the I content of various vegetables, the increase ranging from 20 to 7900%. There was sometimes a non-essential increase in the mineral content. R. C. WILLSON

**Comparative experiments with sodium nitrate, Chile saltpeter and calcium nitrate.** J. WEIGERT. *Mitt. deut. Landw.* 44, 261-5(1929).—There were no significant differences between the 3 fertilizers tested on wheat, oats and hay. Tested on potatoes,  $NaNO_3$  (Chile) gave the highest,  $Ca(NO_3)_2$ , the lowest, and  $NaNO_3$  (artificial) intermediate yields. B. C. BRUNSTETTER

**Symptoms of potash deficiency in oat plants.** KÖSTLIN. *Ernähr. Pflanze* 25, 224-8(1929).—The appearance of plants grown in pots under potash-deficient conditions is described and illustrated. LAWRENCE P. MILLER

**Physiologic reaction of potash salts.** W. WICHMANN. *Ernähr. Pflanze* 25, 209-12(1929).—From expts. with soils conducted mostly in dishes as used in Neubauer analyses (*C. A.* 18, 877) and with plants in the early stages of growth, it is concluded that potash salts are physiologically neutral. LAWRENCE P. MILLER

**Is the blackening of potato tubers a potash deficiency phenomenon?** F. MERKEN-SCHLAGER. *Ernähr. Pflanze* 25, 275-6(1929).—Some observations of the Eigenheimer variety indicate that melanin formation is more rapid in tubers grown under low potash conditions. LAWRENCE P. MILLER

**The distribution and accumulation of the important potash salts in potato stems.** W. VON BREHMER AND J. BÄRNER. *Ernähr. Pflanze* 25, 300-6(1929).—Plants were grown in pots with increasing amts. of sulfate, phosphate, nitrate, and chloride of K. At the end of the vegetative period sections of the stems were tested with  $H_2PtCl_6$ . Conclusion: The  $K_2O$  content and development of those tissues most important to the life of the plant are proportional to the amt. of  $K_2O$  available. This is no longer true if growth is depressed by excess  $K_2O$ . LAWRENCE P. MILLER

**The so-called marginal leaf scorch of currants and its control.** T. A. C. SCHOEVEERS. *Ernähr. Pflanze* 25, 297-300(1929).—An expt. is described in which potash fertilization corrected this condition. LAWRENCE P. MILLER

**Investigations on the influence of fertilization on the susceptibility of flax to the rust fungus (*Melampsora lini*).** E. BUDBERG. *Ernähr. Pflanze* 25, 220-4(1929).—Plants grown on plots fertilized with potash were more resistant. L. P. M.

**Combating organisms harmful to plants and fertilizing with sulfur.** BRUNO WÄSER. *Metallbörse* 18, 733-4, 845-6(1928).—A discussion and review. E. F. S.

**Fish oil as an adhesive in lead arsenate sprays.** CLIFFORD E. HOOD. U. S. Dept. Agr. *Tech. Bull.* 111, 1-28(1929).—The use of fish oil as an adhesive in lead arsenate sprays for gypsy-moth extermination and general control work permits a reduction in the quantity of lead arsenate used from 6.25 to 5 lb. per 100 gal. of water. If the spraying is done when the larvae are less than half grown the proportion of lead arsenate in the mixt. can be still further reduced. Fish oil is likewise a good adhesive to use with Bordeaux mixt. or a combined lead arsenate and Bordeaux mixt. It should be added to the spray mixts. at the rate of 4 oz. by wt. per lb. of lead arsenate powder or insol. matter used. W. H. ROSS

**Experiments with pine oil preparations (as insecticides).** ERNEST N. CORY. Univ. Maryland Agr. Expt. Sta., *Bull.* 298, 184-6(1928).— $p-C_6H_4Cl_3$  was dissolved in pine oil, the soly. being about 1 g. in 2 cc., and the soln. was then emulsified with soap. The dil. emulsion is effective against the peach borer (*Aegeria exitiosa*) without injury to apple or peach trees. The higher fractions of pine oils seem to be the more toxic to insects. C. H. RICHARDSON

**The effectiveness of several grades of carbon disulfide (as insecticides).** ERNEST N. CORY. Univ. Maryland Agr. Expt. Sta., *Bull.* 298, 192-5(1928).—Com. grades of

CS<sub>2</sub>, compared favorably with C. P. grades as fumigants for insects. Conditions for fumigation with CS<sub>2</sub> are discussed. C. H. RICHARDSON

An apparatus for obtaining measured areas of sprayed foliage for chemical analyses. JOSEPH M. GINSBURG. *J. Agr. Research* 36, 1007-9 (1928).—An app. which cuts circular disks from leaves is described. Amts. of As<sub>2</sub>O<sub>3</sub> and SO<sub>2</sub> on apple leaves sprayed with mixts. contg. PbHAsO<sub>4</sub>, S and Fe<sub>2</sub>O<sub>3</sub> were closely similar whether the analysis was made upon entire leaves or from leaf disks cut by the app. described. C. H. R.

Utilization of chloropicrin against scale insects destructive to the orange tree and date palm. ANDRÉ PIÉDALLU AND A. BALACHOWSKY. *Compt. rend.* 187, 671-3 (1928).—Chloropicrin is used to fumigate trees covered by tents as with HCN. The compd. is evapd. by means of alc. or petroleum oil lamps. Fifteen to 20 g. per cu. meter killed scale insects of 7 species on orange trees and date palms. Tender growth and blossoms of the orange are injured by this dosage but the winter foliage is not. Winter is also advised for treatment of young date palms. Cf. Bertrand, C. A. 14, 2526. C. H. R.

Insects and chemistry. WILLEM RUDOLFS. *J. Chem. Education* 6, 1100-12 (1929).—The question of insect control can be divided into 2 parts: (1) the physiology and chemistry of insects and (2) production of cheap and efficient insecticides. E. J. C.

The use of sugar-cane waste products as cheap and effective larvicides. E. R. RICKARD, P. DÍAZ QUIETA AND ALBERTO NÚÑEZ. *Semana méd.* (Buenos Aires) 36, 174-6 (1929).—Larvae never develop in the waste waters of the distilleries, but the larvicide action of fusel oil, second runnings and residues is not strong enough to justify their use as larvicides when transportation is required. A. E. MEYER

The extermination of the fungus *Cercospora beticola* on beets. F. X. KREŠL AND ARNOLD PESKA. *Listy Cukrovar.* 47, 439-42 (1929).—Three sprayings at 8- and 30-day intervals were made on a com. scale in July and Aug. An aq. suspension of Bordeaux mixt. produced plants 10 cm. taller than untreated ones and free from *Cercospora* "Peronoid" (a dry mixt. of CuSO<sub>4</sub> and CaO) was less effective. "Cusisa" (a Cu-As prepn.) was ineffective. FRANK MARESH

Seed treatment for black-leg disease of crucifers. E. E. CLAYTON. N Y State Agr. Expt. Sta., *Tech. Bull.* 137, 58 pp. (1928).—A report of expts. with seed treatments for black-leg (*Phoma lingam* (Tode) Desm.) on cabbage and Brussels sprouts. The dust disinfectants tested included Semesan, Semesan Jr., Bayer dust, Cu carbonate and many others. None of the dust treatments can be recommended for use against black-leg. The liquid chem. treatments included HgCl<sub>2</sub>, Semesan, Uspulun and Germisan. Germisan was very effective against black-leg, but the treatment was liable to injure the seed. Uspulun was safe, but little more effective than standard HgCl<sub>2</sub>. Semesan liquid treatment was much less effective than HgCl<sub>2</sub>. None of the chem. soaking treatments can be recommended for black-leg. Hot-water treatments at 50°, 55° and 69° were tested, and effective black-leg control was secured at all temps. by regulating the length of exposure. It is recommended that cabbage and Brussels sprouts seed be soaked 25 min. in water at 50° as the most satisfactory protection against black-leg infection. E. F. SNYDER

Potash requirements of the opium poppy (GAROLA) 11D. Analysis of insecticides containing F compounds (HART) 7. A drop test for the estimation of the stability of emulsions (GOETTSCH) 7. Products for use in fungicides, insecticides, etc (Brit. pat. 302,666) 29. Wood-preserving composition (U. S. pat. 1,720,905) 20.

Fertilizer. CHEMIEVERFAHREN GES. Brit. 302,148, Dec. 10, 1927. Crude phosphate is treated with K<sub>2</sub>SO<sub>4</sub> and HNO<sub>3</sub> in sufficient quantities to form CaSO<sub>4</sub>, KNO<sub>3</sub> and H<sub>2</sub>PO<sub>4</sub>, the CaSO<sub>4</sub> is sepd. by filtration, and the filtrate is neutralized with NH<sub>3</sub> and evapd. to dryness.

Fertilizers. COMPTOIR COMMERCIAL DES ENGRAIS PARIS-AUBY. Fr. 673,085. Apr. 19, 1928. A dry non-hygroscopic fertilizer is prepd. by mixing vinasses from distilleries and sugar factories with a basic substance such as CaO, CaCO<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>, Ca(CN)<sub>2</sub> or dephosphorization slags, in the presence of an excess of acid such as H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, HNO<sub>2</sub>, H<sub>2</sub>SO<sub>3</sub> or phosphoric acid.

Fertilizer from town refuse. A. FABERJ. Brit. 302,290, Dec. 13, 1927. Town refuse is converted into a nitrogenous fertilizer by treatment with hot SO<sub>2</sub> in a tower to which air is also supplied which converts SO<sub>2</sub> into SO<sub>3</sub> which forms H<sub>2</sub>SO<sub>4</sub> with the moisture present so that the acid fixes the N in the refuse. Various details are given. The product may be mixed with phosphorite or other fertilizing materials.

**Fungicide.** JOHANN H. HORST. Ger. 477,502, Aug. 16, 1924. Addn. to 427,075. A prepn. for preventing the growth of fungus, especially peronospora, consists of a mixt. of finely powd.  $\text{CuSO}_4$ , lime, kieselguhr, casein,  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{SiF}_6$  with the further addn. of powd.  $\text{NaHCO}_3$ . Starchy substances such as flour may also be added.

**Fumigating composition for plants.** I. G. FARBENIND. A.-G. (Friedrich Wissing, inventor). Ger. 477,532, Mar. 18, 1922. A  $\text{SO}_2$ -liberating agent for destroying pathogenic spores on plants is made by mixing S(94%) with noninflammable indifferent material such as kieselguhr (6%).

**Fumigating composition for plants.** I. G. FARBENIND. A.-G. (Martin Müller-Cunradi and Josef Jannek, inventors). Ger. 477,660, Sept. 5, 1924. Plants are preserved from pests and vermin by  $\text{SO}_2$  generated by active C mixed with S and oxidizing material such as  $\text{NaNO}_2$ .

**Treating seeds.** BAYERISCHE STICKSTOFF-WERKE A.-G. Ger. 478,123, May 24, 1924. In stimulating seeds by treatment in known manner with suitable solns., the seeds are heated at 30–55° before the treatment and are air-dried as completely and rapidly as possible after the treatment.

**Weed killer.** CHEMISCHE FABRIK LUDWIG MEYER. (Fritz Wolff, inventor). Ger. 478,446, Aug. 31, 1927. Addn. to 441,213. According to Ger. 441,213, a soln. of a heavy metal nitrate, particularly  $\text{Cu}(\text{NO}_3)_2$ , of 1.5–7% concn. is used as a weed killer. A proportion, suitably one-third, of the nitrate is now replaced by the corresponding sulfate.

**Vermin-destroying compositions.** CHEMISCHE FABRIK HUGO STOLTZENBERG. Ger. 478,445, May 21, 1925. Comps. for spraying on plants are prepd. by heating an alc. soln. of resin with a small amt. of caustic alkali and dilg. the product with water.

**Vermin-destroying compositions.** IGNATZ KREIDL. Austrian 113,334, Jan. 15, 1929. Vermin-destroying comps. to be applied by dusting are prepd. by soaking starch or like colloid in a soln. or suspension of a fungicide, insecticide or disinfectant, etc., and then filtering and drying.

## 16—THE FERMENTATION INDUSTRIES

C. N. FREY

**Making and grading industrial alcohol.** H. W. HAINES. *Chem. Markets* 25, 41–3(1929). E. H.

**The effect of certain metals on the acetic acid fermentation.** M. ROZENBLATT and M. MORDKOVICH. *Biochem. Z.* 209, 83–9; *Ukrainskii Khim. Zhur.* 4, Tech. Pt. 1–10(1929).—The activating effect of Ni and of Co rises very rapidly but falls just as suddenly with increasing concn. of the metal. On the contrary, Fe and Mn have a much less pronounced catalytic effect on the AcOH fermentation but the inhibiting action likewise occurs at relatively much greater concns. as compared to Ni or Co. Thus at a concn. of  $\frac{1}{1000}$  % Ni and Co only 51 and 86%, resp., of the AcOH (control) is formed whereas Fe or Mn has no effect. From the point of view of the paralyzing action on the enzymes of AcOH fermentation, the metals fall into this series Ni > Co > Fe > Mn.

S. MORGULIS

**Timely pointers on the production and marketing of cider.** PAUL F. YOUNG. *Fruit Products J. and Am. Vinegar Ind.* 8, No. 9, 10–12; No. 10, 9–11; No. 11, 7–9 (1929).

J. A. KENNEDY

**Malt vinegar and its manufacture.** PAUL HASSACK. *Fruit Products J. and Am. Vinegar Ind.* 8, No. 3, 19–20; No. 5, 24–6; No. 7, 30–1; No. 9, 18–9; No. 11, 19–21 (1929).—H. describes a simple form of manuf. wherein barley is employed as the prime material. Formulas and operations are discussed; also such details as pitching of sweet wort with yeast, fermentation of the wort, prevention of infection, storage of guiles, double tiers of packing to increase production of generators, storage and treatment of the crude malt vinegar. H. describes a typical English acetifier. J. A. KENNEDY

**The influence of the malting process on the fat content of barley.** K. TÄUFEL and M. RUSCH. *Biochem. Z.* 209, 55–61(1929).—During malting of barley there is a loss of liquid fat acids, chiefly of oleic acid.

S. MORGULIS

**Heating of the vintage (before pressing).** J. DUBAQUIÉ. *Ann. fals.* 22, 211–3 (1929).—A certain proportion (about  $\frac{1}{10}$  to  $\frac{1}{5}$  of the vintage) of the grapes is heated, before stemming and pressing, for several hrs. at about 40–50°; it is then pressed, and added to the remainder of the must after tumultuous fermentation is completed. The heating destroys any germs present on the grapes, results in the retention of a higher

proportion of the pectins, imparts a remarkable brilliancy to the finished wine and improves the mellowness and flavor such as would result from aging. A. P. C.

**General method for the determination of corrected volatile acidity of wines.** R. MARCILLE. *Ann. fals.* 22, 224-5(1929).—Mathieu's method (*C. A.* 21, 3418) is not applicable to wines having a high aldehyde content; the production of a large amt of aldehydes is caused by the use of large doses of  $\text{SO}_2$ . The true org. volatile acidity is given by total volatile acidity—free  $\text{SO}_2$ —0.7 of the combined  $\text{SO}_2$ .

**The detection of fruit juice (fruit wine) in grape wine.** J. WERDER. *Mitt. Lebensm. Hyg.* 20, 7-14(1929); cf. *C. A.* 23, 1928.—Adulteration of grape wine by the addn of 10% or more of other fruit wines is detected by the identification of sorbitol, present in fruit wines other than grape. Sorbitol is sepd. as dibenzalsorbitol by treating the sample concd. to a sirup, with an approx. equal amt. of 1:1  $\text{H}_2\text{SO}_4$  and  $\text{BzH}$ . B. C. B.

**The formation of hexaacetylsorbitol from dibenzalsorbitol.** C. ZACH. *Mitt. Lebensm. Hyg.* 20, 14-5(1929); cf. preceding abstr.—Dibenzalsorbitol which cannot be purified by recrystn. and has no definite m.p. is split by heating at least 0.05 g. with 2 cc. *N*  $\text{H}_2\text{SO}_4$  1 hr., extg. the  $\text{BzH}$  with ether, removing  $\text{H}_2\text{SO}_4$  as  $\text{BaSO}_4$ , concg. to a sirup, then acetylating by Tutin's technic (heating 1 hr. with 0.5 cc.  $\text{Ac}_2\text{O}$  and 1 drop pyridine, then adding 5 cc.  $\text{H}_2\text{O}$ ). B. C. BRUNSTETTER

**The detection of fruit wine by the sorbitol method.** FIESSELMANN. *Mitt. Lebensm. Hyg.* 20, 45-6(1929); cf. preceding abstr.—The sorbitol method for detecting adulteration of grape wine with other fruit wines is recommended as a certain lab. method which can be easily and quickly performed. B. C. BRUNSTETTER

**The wines of the coöperative cellars of the Hérault (1928 vintage).** E. HUGUES AND R. CHEVALIER. *Ann. fals.* 22, 207-11(1929).—Analyses of 18 wines of known origin and purity are tabulated and briefly discussed. A. PAPINEAU-COUTURE

**New data on saturnism (KOHN-ABREST) 13.** An apparatus for removing foams from samples of liquors (HERNYCH) 1. Retting flax fiber [with alcohol as by-product] (Brit. pat. 302,300) 25. Saccharification of wood [with fermentation or "working into yeast" of waste liquors] (Brit. pat. 302,313) 23.

**Citric acid.** MONTAN UND INDUSTRIALWERKE VORM. J. D. STARCK. Brit. 302,338, Dec. 16, 1927. In effecting fermentation of carbohydrates by mold fungi such as *Aspergillus niger*, the mold stock is cultivated in alternating stages including cultivation in solid media of the gelatin and agar agar type, cultivation in liquid media under conditions of industrial fermentation, and cultivation on vegetable culture media such as fruit pulp, contg. org. acids and vitamins. Various details and auxiliary treatments are described. Cf. *C. A.* 23, 3300.

**Fermented beverages of low alcohol content.** HERMAN HEUSER (to U. S. Process Corp.). U. S. 1,720,329, July 9. An alc. fermented cereal wort is heated to remove alc. and reduce the alc. content to below the legal limit, treated with heccone ext., cooled and subjected to a secondary fermentation.

**Malt kiln.** WENZL A. KURZ and KARL KOLLER. Austrian 113,312, Jan. 15, 1929.

## 17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

**The commercial utilization of Java citronella oil.** BRENDAN O'DONOGHUE, JAMES DRUM AND HUGH RYAN. *Sci. Proc. Roy. Dublin Soc. [N.S.]* 19, 113 20(1928).—A sample of oil  $d_{15}^{20} 0.8918$ ,  $[\alpha]_D^{20} -2^\circ 48'$ , contained acetylatable material and esters 83.3% and aldehyde (citronellal) 45%. Citronellal was pptd. with  $\text{NaHSO}_3$ . The oil remaining was hydrolyzed by alc. KOH and the geraniol sepd. by forming a cryst. double compd. with  $\text{CaCl}_2$ . The geraniol was sepd. from this compd. by decompn. with  $\text{H}_2\text{O}$ , and steam distn. Attempts to sep. citronellol were unsuccessful. The citronellal was reduced to citronellol electrolytically with Pb electrodes and dil. alkali as electrolyte. PAUL BOONE

**New paths of therapy.** J. J. HOFMAN. *Pharm. Weekblad* 66, 569-77(1929).—An address, touching briefly upon recent developments in antiseptics, ph. adjustment, isotonic solns., hormones, vitamins and x-ray chemicals, from the viewpoint of the pharmacist. A. W. DOX

**Investigation of moors (bogs) for balneological purposes.** K. STOCKFISCH AND W. BENAIDE. *Z. angew. Chem.* **42**, 663-8(1929).—Results of chem. and phys. examn. of 9 "moors" used for therapeutic reasons are reported, together with the methods of analysis employed. Included are proximate analyses for  $H_2O$ , sand, ash and org. matter; analysis of dry substance for oxides of Fe, Ca, Mg and S (also S as sulfide), bitumen, total humus, cellulose and hydrolyzable substances; water-sol. salts, pH, degree of conversion into peat, sp. gr.,  $H_2O$  capacity, distribution no. (ratio of vol. sample of peat +  $H_2O$  needed for satn.: vol. of sample), sp. heat (5% dry substance), and relative speed of heat transfer (5% dry substance.) W. C. EBAUGH

**Helabon (formerly helamon).** C. A. ROJAHN AND F. GEWEHR. *Apoth. Ztg.* **44**, 807-8(1929).—Recent analysis of this product indicates a mixt. of antipyrine about 70, pyrimidone 16.7, veronal 13.3%. W. O. W.

**Use of the yeast product "Zyma" in the manufacture of pills.** WOLFGANG BRANDRUP. *Apoth. Ztg.* **44**, 855-8(1929).—Expts. are described using this yeast as a vehicle in connection with the manuf. of pills contg. digitalis, Fe compds., alkaloids, exts., resins, plant juices, balsams, essential oils, guaiacol, creosote and a variety of special combinations with org. and inorg. salts, some 50 in no. W. O. E.

**Capsifor.** C. A. ROJAHN AND MAX HERTER. *Apoth. Ztg.* **44**, 858(1929).—A gelatinous product for external application in the treatment of rheumatism has an odor of Me salicylate, menthol and oil of rosemary, and contains in addn. to these substances  $NH_4$ , camphor and capsicum. The Me salicylate originally incorporated has in some measure been saponified into Na and  $NH_4$  salicylates. W. O. E.

**Skatole.** H. STANLEY REDGROVE. *Perfumery and Essential Oil Record* **20**, 193-5(1929).—A discussion of the relationships existing between skatole and indole, its known and possible isomers, in connection with their use in perfumery. Three different tests, the Ehrlich, vanillin and dimethylaniline tests, for differentiating skatole from indole are outlined. Mention is made of the several chem. methods for prepg. indole, skatole and similar compds. designed as substitutes for civet. W. O. E.

**Examination of pharmaceutical specialties and nostrums.** C. A. ROJAHN AND FRANZ STRUFFMANN. *Pharm. Zentralhalle* **70**, 325-32, 341-6, 405-9(1929).—A comprehensive scheme of analysis (including preliminary tests) for the detection of crude drugs, their active principles and unknown mixts. with other materials. W. O. E.

**Production of crude drugs in Poland.** JAN MUSZYNSKI. *Pharm. Zentralhalle* **70**, 438-41(1929).—An account of the collection and traffic in crude drugs (naturally grown) in or adjacent to the district of Swienciany. W. O. E.

**Scientific pharmacy.** RAPP. *Pharm. Ztg.* **74**, 903-6(1929); cf. *C. A.* **23**, 3304.—A comprehensive treatment of the tablet industry, notably the mech. appliances involved, the preliminary prepn. of the material (therapeutically active agents) to be compressed, granulation, binders, fillers, lubricants, disintegrators, etc. W. O. E.

**Relation of potassium to iron in the combustion of cigar leaf tobacco.** D. E. HALEY AND OTTO OLSON. *Science* **70**, 17-8(1929); cf. *C. A.* **23**, 479.—Exptl. evidence has been developed indicating that good combustion of cigar leaf tobacco is assocd. with K compds. which give rise to  $K_2CO_3$  during combustion, and that the presence of such compds. may serve to intensify the catalytic effects of Fe on this process. W. O. E.

**New medicaments and pharmaceutical specialties of the first quarter of 1928.** F. ZERNIK. *Sudder. Apoth. Ztg.* **68**, 410-12, 417-8(1928); cf. *C. A.* **23**, 3773.—A compilation H. G.

**Quantitative determination of formaldehyde in a pharmaceutical preparation.** OSCAR HEIM. *Ind. Eng. Chem., Anal. Ed.* **1**, 128(1929).—To 10 cc. of sample contg. about 0.2%  $CH_2O$  add 2 cc. of concd. HCl and 10 cc. of N  $AgNO_3$ . Shake and add immediately 4 cc. of 50% NaOH. Shake and let stand 30 min. with occasional shaking. If formaldehyde is present the  $AgCl$  ppt. will at once turn black. Filter, wash with hot water and dissolve the reduced Ag with 3.75 N  $HNO_3$ . Dil., add HCl and weigh the resulting  $AgCl$ .  $2 AgCl = 1 CH_2O$ . W. T. H.

**Synthetic perfumes.** H. STANLEY REDGROVE. *Science Progress* **24**, 72-80(1929).—A concise outline of the syntheses of the org. compds. which are the active principles of the natural perfumes. JOSEPH S. HEPBURN

**The decomposition products of anesthetic ether and their determination.** B. SAMDAHL. *Norg. Apotekerfor. Tids.* **37**, 148, 161, 181(1929).—A lecture. K. H.

**The examination of cultivated gorli seeds.** M.-TH. FRANÇOIS. *Bull. sci. pharmacol.* **36**, 339-42(1929).—*Oncoba echinata* Oliver was cultivated as a possible source of chaulmoogra oil. 100 l. of the seeds weighs 60 kg. and contains 48% of oil. This m.  $44^\circ$ ;

$d_{20} 0.944$ ;  $n_D^{20} 1.4732$ ;  $\alpha_D = +49^\circ 55'$  in 5%  $\text{CHCl}_3$  soln. and calcd. for the pure oil; acidity practically 0; sapon. value 190; I value Hanus 95. The fatty acids m.  $58-59^\circ$ ; satn. value 203; av. mol. wt. 275; I value Hanus 96.9;  $\alpha_D = +50^\circ 20'$ .  
A. E. MEYER

The determination of the total alkaloids of the cinchona. M. MASCRÉ. *Bull. sci. pharmacol.* 36, 351-2(1929).—The difficulties presented by the method of the Belgian pharmacopeia are discussed.  
A. E. MEYER

A study of the Japanese peppermint oil. III. YEINOSUKE SHINOZAKI AND TORIHI NAGAZAWA. *Repts. Imp. Ind. Research Inst. Osaka, Japan* 10, No. 4(1929); cf. *C. A.* 21, 1690.—The oil of *kusa-hakka*, grown wild in Hokkaido, resembles peppermint oil. It is slightly acidic; it is yellow-green but on standing it changes to brown,  $d_{20}^{20} 0.9181$ ,  $n_D^{20} 1.4675$ ,  $[\alpha]_D^{20} -14.54^\circ$ , sapon. value 11.30, and sapon. value after acetylation 105.80. It gives Liebermann's reaction. *Kusa-hakka* oil contains *l*-menthone (40-50%), pulegone (20%), *l*-menthol (30%) and minor constituents such as  $\text{HCOOH}$ ,  $\text{AcOH}$ , water-sol. compd. m.  $187-8^\circ$ , certain phenolic compds. m.  $185-6^\circ$ , *l*-limonene, pinene, *d*-isomenthone and certain alcohols. The use of *kusa-hakka* oil with a view to produce menthol is discussed. IV. *Ibid* No. 5.—The chief constituents of Japanese peppermint oil are *l*-limonene, menthone, inactive isomenthone, *d*-isomenthone, menthone, *l*-menthol,  $\alpha$ -pinene, camphene, ethylamylcarbinol,  $\beta$ , $\gamma$ -hexenol and certain free and combined acids. Index of refraction of the hexenol was 1.44 instead of 1.48 as reported by Walbaum (*C. A.* 12, 2230). The phys. properties of the mixt. of menthol and menthone, menthol and acetylmenthol in different concn. were also studied with a view to make it a standard for future use.  
F. I. NAKAMURA

Investigations into buffer antiseptics. J. K. GJALDBAEK. *Dansk Tids. Farm.* 3, 1-75(1929).—"Buffer antiseptics" include all forms of antiseptic medicines which contain a supply of an antiseptically active compd. in a more or less latent or inactive form and are able to transfer the active antiseptic to liquids, e. g.,  $\text{H}_2\text{O}$ , tissue juices, etc., with which they come in contact. *A*-activity (*A* = antiseptic) is defined as *A*-concn. (usually g. per 100 g. soln.) of an aq. soln. in equil. with buffer-*A*. *A*-capacity is the total quantity of removable *A* (in g.) per 100 g. buffer-*A*. The *A*-buffer power is the ability of the buffer-*A* to maintain a certain activity. A buffer-*A* is thus characterized by the following properties: (1) The total *A*-concn. (active and inactive form) is greater than the *A*-activity. (2) When *A* is partially removed the *A*-activity decreases less than does the *A*-concn. Examples of buffer-*A* of the type, "chemically bound *A*" are  $\text{NaAgS}_2\text{O}_4$ , which liberates antiseptically active  $\text{Ag}^+$  while the undissoed. mol. forms the inactive supply, and  $\text{I-KI}$  solns., where the  $\text{I}_2$  is the active *A*, and  $\text{I}_2$  the inactive supply. Examples of buffer-*A* of the type "ordinary solns." are solns. of phenols in glycerol,  $\text{EtOH}$  and fatty oils. The degree of satn. in every solvent furnishes an approx. measurement of the activity of the solute. Examples of buffer-*A* of the "adsorption" type are  $\text{I}_2$ -carbon mixts.  $\text{I}_2$  adsorbed by *C* is inactive, while  $\text{I}_2$  in  $\text{H}_2\text{O}$  is active. Extns. of a large no. of phenol preps. were made at  $18^\circ$  and  $37^\circ$ . The partition coeff. of phenol between oil and  $\text{H}_2\text{O}$  was detd. as 0.12. Oleic acid and several fatty oils except castor oil all showed a partition coeff. of 5-6, while in castor oil and camphor the partition coeff. varied with concn. of phenol. From the results obtained G. proposes to express the formulas of official preps. in such a manner that physicians may prescribe phenol preps. of known properties.  
A. O. NELSON

Pharmacological investigation with ergot preparations. TULLIO MENECHINI. *Arch. farmacol. sper.* 46, 259-66(1929).—The method of Broom and Clark (*C. A.* 18, 153) for estg. the content of ergot alkaloids in ergot preps. was studied and found to be accurate.  
G. SCHWOCH

The behavior of protargol solution (Bayer) in presence of several chemical products. V. ZANOTTI. *Boll. chim. farm.* 68, 395(1929).—A 0.5% soln. of protargol (Bayer) was mixed with solns. of different chemicals and the following changes were noted: with pyrazolone (S. chim. des usines de Rhône), no change; with antifebrin, no change; with  $\text{EtOH}$ , turbidity; with acetylsalicylic acid (Rhodine), flocculent gray ppt.; with aspirin (Bayer), flocculent gray ppt.; with phenacetin (Bayer), no change; with antipyrine (Knole), no change; with pyrimidone (Meister Lucius), reddish brown color, gray in transparent light. When 50 mg. of pyrimidone (Meister Lucius) was added to 2 cc. of a 1% protargol soln. and the mixt. was agitated slowly, the pyrimidone dissolved and the yellow color changed to reddish brown. After about 30 min. the whole soln. became turbid. The last 3 reactions are of possible value for the distinction of antipyrine and pyrimidone.  
G. SCHWOCH

**Emetine.** ANON. *Hyg. du travail*, Geneva 1929; *Ann. hyg. publ. ind. sociale* 1929, 369.—Emetine is an alkaloid obtained from the ipecacuanha root and used especially in tropical medicine. The formula is  $C_{23}H_{16}N_2O_4$ . Its toxic effects are discussed.

**Pharmacognostical investigation of ginger or "Rhizoma Zingiberis."** K. KIMURA AND M. WATANABE. *J. Pharm. Soc. Japan*, 49, 366-76 (1929).—"Japan ginger" has 3 kinds of starch grains, *i. e.*, simple, compound and partially compound. The partially compound starch grains are very common in Japanese ginger and constitute a majority of the larger grains, which makes the "Japan ginger" differ from other varieties. NAO UYEI

**An appliance for filling amyl nitrite capsules.** W. A. N. MARKWELL. *Pharm. J.* 121, 124 (1928).—The supply of amyl nitrite (*A*) is contained in a large pear-shaped separatory funnel whose stem is bent upward in U shape and drawn out at the end to about 2 mm. width. *A* is withdrawn from the end of this tube and put into capsules by means of a graduated glass hypodermic syringe. When the level of the liquid in the tube becomes low, it can be easily raised by giving the vessel a slight clockwise turn and clamping it in this position.

**Examination of the adsorptive properties of medicinal kaolin.** J. RAE. *Pharm. J.* 121, 150-1 (1928); cf. Grettie and Williams, *C. A.* 22, 1510.—From examn. of 14 samples of kaolin for medicinal use, this test is deduced: Two g. dried to const. wt. when shaken occasionally during 30 min. with 70 cc. of a 0.04% aq. soln. of methylene blue, should yield a colorless filtrate. In 5 samples of kaolin, 2 g. adsorbed 30, 26, 24, 20 and 18 cc. of 0.01 *N* piperidine. NaCl, oxalic and citric acids were not adsorbed.

**The pharmaceutical laboratory of the University of Utrecht.** HENRY G. GREENISH. *Pharm. J.* 121, 156-8 (1928).—Descriptive of courses, with photographs of buildings and interiors.

**Scientific Japan, its contribution to modern pharmacy.** BERNARD E. READ. *Pharm. J.* 121, 199-201 (1928).—An historical and descriptive account is given of Japanese activities in medical botany, chemistry and pharmacy, with photographs and references.

**The pawpaw (Carica papaya).** S. G. WILLIMOTT. *Pharm. J.* 121, 219 (1928).—An account is given of the botany, distribution, the fruit and the cultivation of the pawpaw tree, and of the properties of *papain*, the proteolytic enzyme of the fruit, seeds and leaves.

**Ammonium carbonate, Brit. Pharm. in dispensing.** R. A. CRIPPS AND F. W. HOVLAND. *Pharm. J.* 121, 236-7, 270 (1928); cf. Self and Corfield, *C. A.* 20, 2562.— $NH_4$  carbonate ( $NH_4HCO_3 \cdot NH_4NH_2CO_3$ ) (*A*) by exposure loses about 33% of the total N present in 2 hrs. The loss probably depends both on temp. and moisture in air. Soln. of *A* if kept in a well-closed bottle retains its alky. Accurate dispensing is therefore possible with a standardized soln. of *A* (1 in 8 or 1 in 10) prepd. from the salt in translucent non-powd. lumps, dissolving it in the  $H_2O$  in a closed vessel. It is suggested that  $NH_4HCO_3$  be made official in place of *A*, on account of its greater stability. The dose will then have to be increased to a max. of 15 grains.

**The keeping properties of hydrargyrum cum creta, Brit. Pharm.** J. R. WALMSLEY. *Pharm. J.* 121, 254-5 (1928).—When kept under av. conditions, there is no loss of Hg from folded powders of the mixt., which contains 33.5% Hg. When exposed to the sun's rays, or in proximity to metallic surfaces which tend to absorb Hg (Al foil, tin, etc.), there may be a slight loss of Hg, *i. e.*, 0.6 to 1%. However, storage in a warm place, *e. g.* near a stove, may cause a rapid and even complete loss of Hg.

**Studies of anesthetic ethylene: 1. The odor of ethylene.** H. S. BOOTH AND M. B. CAMPBELL. *Anesthesia and Analgesia* 8, 221-6 (1929).—Pure ethylene, obtained by numerous fractional distns., has a characteristic sweet, musty odor, which is apparently inherent in ethylene itself. Commercial anesthetic ethylene (made by dehydration of alcohol) purified in the same way has the same odor, indicating that it is practically pure. Commercial anesthetic ethylene made by cracking hydrocarbons has an odor distinctly different from that prepd. from alc.; it is offensive, rather strong and to some is nauseating.

**The detection of small traces of carbon monoxide in ethylene.** BURNHAM S. WALKER AND OTIS EDWARD ALLEY. *Anesthesia and Analgesia* 8, 227-9 (1929).—All methods for the detn. of CO in ethylene that involve removal of ethylene by Br-water or fuming  $H_2SO_4$ , are subject to error caused by oxidation of CO to  $CO_2$ . The reagent of Manchot and Scherer (AgOH in pyridine) appears to be specific for CO in the presence of ethylene under certain conditions of alky. Of other methods, the pyrotannic acid

method of Sayers, Yant and Jones is recommended as most satisfactory for use in hospital laboratories.

R. C. WILLSON

**The stability of digitalis and its preparations.** HARVEY B. HAAG AND ROBERT A. HATCHER. *J. Am. Med. Assoc.* 93, 26-9 (1929).—Six specimens of powdered digitalis were examd. after intervals of 1-16 yrs.; in no case was deterioration noted. A sterile infusion of digitalis undergoes little change within several months, and deterioration results then in diminished activity, not increased toxicity. Official tincture of digitalis retains its activity with comparatively little change during several years, and that change merely calls for a corresponding increase in dosage. The liquid preps. of digitalis are not as stable as powdered digitalis kept with ordinary care in a corked glass bottle. Aqueous solns. of strophanthin, ouabain and other digitalis principles, kept in ampoules of soft glass, deteriorate rapidly. Ouabain soln. in hard glass decomposes slowly.

R. C. WILLSON

Detoxifying, diffusing, germicidal and surface-tension-depressing properties of soaps (DAVISON) 27. A chemical study of the rind of California oranges (MATLACK) 11D. Determination of glucosides (ZECHNER) 7. Detection of isopropyl alcohol in alcoholic preparations (STAINIER, LAUWAET) 7. Depsides (ASTRADA) 11D. Synthetic morphine (WEBER) 10. The digitalis glucosides. III. Gitoxigenin and isogitoxigenin (JACOBS, GUSTUS) 10. Origin of ethereal oils in plants (FRANCESCONI) 11D.

THOMS, HERMANN F. M.: *Grundzüge der pharmazeutisches und medizinischen Chemie.* Berlin: J. Springer. 639 pp.

**Medicines.** EDUARD JENA. Ger. 478,167, Mar. 20, 1921. Therapeutically active water-sol. and stable preps. are obtained from albumins and their degradation products by acidifying them with a weak org. acid such as lactic acid and then treating with  $(CH_2)_6N_4$ , which may be in excess. Examples are given.

**Medicine comprising quinine and hematoxylin.** ELMER H. KING. U. S. 1,720,278, July 9. A medicinal prep. which may be used for treating sarcoma, carcinoma, etc., is prepd. by adding hematoxylin to an aq. soln. of quinine-HCl and neutralizing with  $NaHCO_3$ . Prep. of other similar compds. also is described.

**Hydrogenated cinchona alkaloids.** JOHN W. BLADEN (one-half to Howards & Sons, Ltd.). U. S. 1,720,462, July 9. Quinine, dihydroquinine, cinchonidine hydrochloride or other cinchona alkaloids, their dihydro derivs. or salts of the alkaloids or dihydro derivs., are subjected to the action of H in a solvent and in the presence of a catalyst of the Ni group, and during at least the later stages of the treatment a reaction temp. of 40° or higher is maintained.

**Quinoline derivatives.** I. G. FARBERIND. A.-G. Brit. 301,947, Sept. 1, 1927. Mono- and di-ethers of 6,8-dihydroxyquinoline such as the methoxy or ethoxy derivs. are prepd. by alkylation or from derivs. of 4-amino-1,3-resorcinol by Skraup's reaction, and may be used as *therapeutic agents*. Several examples are given.

**Anesthetic.** I. G. FARBERIND. A.-G. Brit. 302,337, Dec. 16, 1927. A rectal anesthetic is formed by use together of tribromoethyl alc. and amylene hydrate.

**Papaverine salts.** KARL FLEISCHER and OTTO HIRSCH-TABOR. Ger. 477,577, Apr. 29, 1924. Salts of papaverine are prepd. by treating salts of the base with cyclic aromatic urea compds. Thus, papaverine-HCl is heated with Na diethylbarbiturate, giving crystals m. 138°. Other examples are given.

**Salts of biliary acids.** CHEMISCHE FABRIK VORM. SANDOZ. Fr. 657,350, Dec. 16, 1927. Cinchona alkaloids such as quinine, quinidine, cinchonine, hydroquinine or synthetic preps. such as the higher alkyl ethers of hydrocupreine are combined with biliary acids to produce salts. Examples are given of the prep. of quinine cholate, quinidine cholate, ethyldihydrocupreine cholate and quinine desoxycholate. Cf. C. A. 23, 3932.

**Pyrazolone barbituric acid compounds.** CHEMISCHE FABRIK VORM. SANDOZ. Brit. 301,727, Dec. 3, 1927. Double compds. of 5,5-disubstituted barbituric acids such as isobutylallyl-, diethyl-, isopropylallyl-, phenylethyl- and *n*-butylallyl-barbituric acids with 1-phenyl-2,3-dimethyl-4-dialkyl (e. g., dimethyl)-amino-5-pyrazolones are prepd. by interaction of the salts of the components in a solvent such as a satd. aq. soln. of the pyrazolone compd. The products are *analgesics and soporifics*.

**(Dimethylamino)-*sec*.-butyl *m*-aminobenzoate.** ÉTABLISSEMENTS POULENC FRÈRES, E. FOURNEAU and J. TREFOUËL (to Soc. des usines chimiques Rhone-Poulenc). Brit. 301,845, Dec. 6, 1927. Details are given of a process for introducing the *m*-amino-

benzoyl group into the OH group of dimethylamino-2-butanol. The *product possesses anesthetic properties*. Its hydrochloride also is described.

**Oxime ethers.** I. G. FARBENIND. A.-G. Brit. 301,956, Sept. 9, 1927. Aminoalkyl ethers of oximes and their salts are prepd. by treating oximes of aldehydes and ketones with aminoalkyl halides. *Therapeutic products* are obtained. Cyclohexanone oxime, camphor oxime or anisaldoxime may be treated with diethylaminoethyl chloride in the presence of NaOEt.

**Theobromine.** A. BOHRINGER. Brit. 302,207, Sept. 12, 1927. Theobromine is extd. from materials such as cacao husks with dil. alk. solns. such as milk of lime on the counter-current principle.

**Removing the bitterness of cascara sagrada.** MAX PENSCHUCK. Ger. 477,858, Dec. 30, 1927. Cascara sagrada is warmed in a powd. condition with distd. water and neutral Na tartarate to 95–98°.

**Compounds for treating sarcoma, etc.** ELMER H. KING. U. S. 1,720,279, July 9, 1927. Compds. suitable for treating sarcoma, carcinoma and similar diseases are prepd. by the interaction of alkaloidal substances such as quinine, quinicine or caffeine with "desaccharated" glucosides such as hematoxylin. Numerous examples, details and modifications are described.

**Swab for applying antiseptics.** JOHNSON and JOHNSON. Brit. 301,572, Sept. 9, 1927. A portion of a swab formed of cotton or like material is satd. with an antiseptic such as a soln. of I or mercurochrome and the remainder of the swab material is treated with ceresin or other suitable liquid-repellent so that it may serve as a handle for the swab.

**Bacterial preparations, etc., analogous to tuberculin.** I. G. FARBENIND. A.-G. Brit. 302,226, Dec. 12, 1927. The process described in Brit. 285,087 (*C. A.* 22, 4726) for prepg. tuberculin is applied to other bacteria and fungi such as *Mycobacter lacticola* or *Streptothrix leproides*, to obtain substances having an action resembling that of tuberculin.

**Dentifrice.** KARL R. VIGANO. Ger. 478,355, Dec. 14, 1926. A dentifrice comprises glyceryl monoformate, with or without ethereal oils.

**Extracting gums, etc., from tobacco by use of acetone.** B. SEFERIADIS. Brit. 302,863, March 19, 1928. An app. is described.

**Extracting nicotine from tobacco.** H. FEDERMANN. Brit. 302,560, July 17, 1928. Fr. 657,840, July 19, 1928. Nicotine is extd. by  $\text{NH}_3$  and the excess of  $\text{NH}_3$  is removed by  $\text{CO}_2$ , in an app. which is described. The  $\text{NH}_3$  charged with nicotine passes to a washer contg.  $\text{C}_2\text{HCl}_3$  or  $\text{CCl}_4$ .

## 18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

**Comparison of modern chamber sulfuric acid plants.** THOMAS R. HARNEY. *Chem. Met. Eng.* 36, 402–6(1929). E. H.

**A new contact sulfuric acid process.** A. O. JAEGER. *Ind. Eng. Chem.* 21, 627–32 (1929); cf. *C. A.* 23, 3053.—A new converter developed embodies double counter-current heat-exchange elements in the upper layers of the catalyst; the lower layers used for completing the reaction are either cooled by radiation or for larger units by heat exchange with cold gas or air. The newly developed catalyst contains V in the non-exchangeable nucleus of non-siliceous base-exchange bodies. It is immune to the poisons for Pt catalysts, and gives high conversions. T. H. CHILTON

**High pressures in the manufacture of synthetic ammonia.** ANON. *Chemistry and Industry* 48, 591–8(1929).—Recent designs in compressing plants are described.

E. M. SYMMES

**The influence of methane upon the synthesis of ammonia.** R. NITZSCHMANN. *Metallbörse* 18, 2525–6, 2583–4, 2753, 2807–8, 2864–6(1928).— $\text{CH}_4$  may occur in the gases used for synthesizing  $\text{NH}_3$ ; it is removed with much more difficulty than are O and CO. Tables and curves are given showing the effect of the  $\text{CH}_4$  upon the synthesis of  $\text{NH}_3$ . W. C. EBAUGH

**The manufacture of commercial anhydrous aluminum chloride.** A. M. MCAFEE. *Ind. Eng. Chem.* 21, 670–3(1929).—The difficulties overcome during a period of many years in developing the manuf. of  $\text{AlCl}_3$  on a com. scale are recounted, and the present process by which Gulf Refining Co. is making 75,000 lb. of  $\text{AlCl}_3$  per day at a cost of

not over 5 cents per lb., using bauxite and Cl, is described. Further improvements resulting in a still further reduction in cost are forecast. Six illustrations are included.

E. G. R. ARDAGH

**Cheap aluminum chloride after fifteen years of chemical engineering development.** A. M. MCAFEE. *Chem. Met. Eng.* 36, 422-4(1929). E. H.

**Caustic soda.** WILHELM KOLB. *Metallbörse* 18, 2581-2, 2638-40, 2693-4, 2750-1, 2806-7, 2861-4(1928).—Although KOH is made from KCl by electrolysis in Germany, NaOH is prep'd. chiefly by causticizing  $\text{Na}_2\text{CO}_3$  obtained by the Solvay process. The processes involved, the app. used, analysis of raw materials, intermediate and finished products, data concerning production, etc., are given.

W. C. EBAUGH

**Methods of preparing basic magnesia.** B. G. PANTELEIMONOV. *Zhur. Prikladnoi Khim.* 2, 199-213(1929).—A 16% soln. of  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$  was mixed in equiv. proportion with an 8.6% soln. of  $\text{Na}_2\text{CO}_3$  at  $20^\circ$  and the ppt. decomp'd. at  $50-90^\circ$  for 10-60 min. At  $50-60^\circ$  the ignition losses of the product were higher than those allowed by the Brit. Pharm. The lightest product was obtained by heating for 20 min. at  $90^\circ$ . As the true sp. gr. increases with the treating temp. the apparent sp. gr. is within certain limits inversely proportional to the true sp. gr. With simultaneous pptn. and decompn. a normal product was obtained at  $60^\circ$  and higher. The product was slightly heavier than that obtained by the former method. Accelerated drying at  $110-115^\circ$  gives good results, contrary to the general belief that the max. permissible temp. is  $100^\circ$ . The ppt. can be washed under pressure without seriously affecting its lightness. Contamination with Ca salts may arise from washing the ppt. with hard water. This can be avoided either by shortening the time of washing or by using chemically treated water. The use of distd. water in the last washing is desirable. Ca salts present in the brine can be settled by boiling the soln. or by adding small quantities of  $\text{Na}_2\text{CO}_3$ . Contrary to the general belief, magnesia is slightly hygroscopic. On exposure to the atm. 3.0024 g. of a carefully purified sample absorbed 0.0008 g. of moisture in 12 hrs., and 0.0017 g. in 66 hrs.

V. KALICHEVSKY

**Production and uses of helium gas.** R. R. BOTTOMS. *Trans. Am. Soc. Mech. Eng.*, Advance paper, May 27-30, 1929, 9 pp. E. I. S.

**Activated carbons.** A. S. SIPYAGIN AND I. M. SOKOLOV. *Zuhr. Sakharnoi Prom.* 1, 17-22(1927).—A review. V. E. BAIKOW

**Adsorption by several charcoals of technical importance.** H. I. WATERMAN, J. GROOT AND M. J. VAN TUSSEN BROEK. *Kolloid-Z.* 48, 146-51(1929).—Adsorptive powers of Carboraffin, Merck's blood charcoal, Purit A and Norit T for Orange ENL (Cassella) and for Schaffer's  $\beta$  salt decrease in the order given.

FRANK URBAN

**Synthetic nitrogen.** SIDNEY B. HASKELL AND H. F. MAHLE. *Chem. Markets* 25, 34-6(1929).—The meaning of the projected increase in nitrogen capacity to markets and prices is discussed. E. H.

**Muscle shoals and the new nitrogen picture.** HARRISON E. HOWE. *Am. Fertilizer* 71, No. 2, 60-4(1929).—A review and discussion of the economic factors involved in the developments that have recently taken place in the fixation of atmospheric N.

W. H. ROSS

**Bentonite.** J. H. FRYDLENDER. *Rev. prod. chim.* 32, 325-8, 357-62(1929).—These articles describe the extn., compn., properties and uses of bentonite. P. T.

**Status of the magnesite industry in the United States.** J. M. HILL. *Eng. Mining J.* 128, 48-51(1929). E. H.

**Treatment of finely divided caliche in factories "T," "U" and "V."** C. M. AUTY, E. B. DONALD, W. H. CLAYTON, AND L. L. MALM. *Caliche* 10, 343-60(1928).—Fines contg. particles up to 3 mm. were treated, resp., (T) in tanks by the Trent process (cf. *Caliche* 3, 352(1921); 5, 433(1924); 9, 35(1927)); (U) by rotary pressure filters after leaching and (V) by vacuum leaf filters after leaching. In T about 2 m. depth of liquids of decreasing density, heated by pipes to about  $80^\circ$  and agitated about 2 hrs., yielded a first ext. that was treated subsequently in the usual Shanks process. Further extns. were returned to the fines system. (U) employed Burt filters after boiling in a tank, and (V) Butters filters. Pressure gave better results than vacuum filtering.

HOWARD FLINT

**Mineral wool.** J. R. THOENEN. *Bur. Mines, Circ. No. 6142*, 13 pp.(1929).—Methods of manuf. are described and production statistics are given. E. H.

**Rolls for printing presses.** E. H. RIESSENFELD AND H. WILLSTAEDT. *Z. angew. Chem.* 42, 677-82(1929).—Information concerning inking rolls for printing presses is guarded as a trade secret, and nothing of value can be learned from the literature. Methods have been developed for detg. tensile strength, water absorption and loss, strength of gel, resistance to pressure, flowing and dropping points, adhesive power,

gelatin content, sugar and  $H_2O$ . Of greatest importance in estg. the quality of a roll are detns. of tensile strength, adhesive properties, strength of gel and the dropping point.

**Cements for marbles.** F. MARGIVAL. *Peintures, pigments, vernis* 5, 614-5 (1928).—Compns. of cementitious character adapted to fill cavities in surfaces of natural marble are described.

**The care and maintenance of hand fire extinguishers.** SIDNEY G. GAMBLE. *Munic. Eng. Sanit. Record* 82, 649(1928).—If chem. extinguishers are filled properly they need not be recharged annually but should be inspected for possible tampering. With little care and attention they should be efficient if needed many yrs. later. "Foam" extinguishers are not safe with electricity. It is dangerous to use  $CCl_4$  and soda-acid extinguishers together.

W. C. EBAUGH

B. HAMILTON

C. H. BADGER

**Manufacture of substances formed through highly endothermic reactions, particularly N compounds.** (Belg. pat. 356,946) 13. Production of  $H_2SO_4$  from substances containing  $CaSO_4$  (Belg. pat. 354,788) 20. Kiln for the treatment of lime, dolomite, natural cement, etc. (Belg. pat. 356,177) 1.

MAUGÉ, LUCIEN: *Les industries de l'azote*. Paris: Ch. Béranger. 684 pp. F. 160.

**Boric acid.** AMERICAN POTASH & CHEMICAL CORP. Fr. 657,452, July 12, 1928. In a cyclic process for the production of  $H_3BO_3$ , a soln. contg.  $Na_2B_4O_7$  is treated with  $H_2SO_4$  to form  $H_3BO_3$  and  $Na_2SO_4$ ; the  $H_3BO_3$  is sepd. by cooling and  $Na_2B_4O_7$  is added and dissolved; the  $Na_2SO_4$  is sepd. with water as water of crystn. and the treatment with  $H_2SO_4$  repeated. The  $Na_2B_4O_7$  used should contain less than 6 mol. of water of crystn. to reduce the amt. of water, and increase the amt. of  $H_3BO_3$  which seps.

**Hydrofluosilicic acid.** WILHELM MÖLLER and WILHELM KRETH. U. S. 1,720,965, July 16.  $SiF_4$  is brought into contact with the surface of a thin film of an aq. medium (such as water on rotating disks) which is successively replaced with another film of the aq. material for further reaction with the  $SiF_4$ . An app. is described.

**Phosphoric acid; hydrogen.** I. G. FARBERIND. A.-G. (Wilhelm Wild and Gustav Wietzel, inventors). Ger. 478,018, Dec. 4, 1925. In the manuf. of  $H_3PO_4$  and H from  $H_2O$  and P at 600-700°, a part of the steam required is raised by using the heat of the reaction gases. Thus, the  $H_3PO_4$  may be condensed at 100° or above in tubes in a boiler at atm. pressure or above, and the residual H-steam mixt. may then be used to raise steam at sub-atm. pressure.

**Phosphoric acid and phosphates.** F. G. LILJENROTH (to Kunstdünger-Patent-Verwertungs A.-G.). Brit. 301,864, Dec. 7, 1927. In production of  $H_3PO_4$  or sol. phosphates by leaching raw phosphates and sepg. the Ca from the soln. as  $CaSO_4$ , a temp. of at least 80° (suitably 95°) is employed for the sepn. so that a cryst. form of sulfate which settles readily is obtained. Various details and modifications of the process are described.

**Sulfuric acid.** MARCEL E. DERRY. Fr. 656,857, June 30, 1928.  $H_2SO_4$  of 12° Bé. and stronger is solidified by pouring into  $Na_2SiO_3$  contg. water. Thus, 100 cc. of  $Na_2SiO_3$  is mixed with 50 cc. of water and made up to 1 l. by pouring in  $H_2SO_4$  of 22° Bé. The product solidifies in less than 1 hr. The product may be used in *storage batteries*, as the acid liquifies under the action of the charging current, and remains solid during discharge and prevents sulfating of the electrodes.

**Sulfuric acid.** SOC. GÉNÉRALE MÉTALLURGIQUE DE HOBOKEN. Fr. 656,615, June 28, 1928. In the manuf. of  $H_2SO_4$  by the chamber process, the reaction towers are placed between the Glover and the first chamber or between the Pb chambers, and are sprayed with a soln. having high concn. in oxides of N, or with a large amt. of a soln. of low concn., in such a way that the evacuated acid from these towers contains less than 0.5% of N compds. calculated as  $HNO_3$  of 36° Bé.

**Solid carbon dioxide.** GES. FÜR LINDE'S EISMASCHINEN A.-G. Brit. 301,741, Dec. 2, 1927.  $CO_2$  is liquefied, cooled almost to its freezing point and the pressure on it is reduced. An app. and various details of operation are described.

**Solidifying carbon dioxide.** W. HESSLING. Brit. 302,359, Dec. 15, 1927. Solid  $CO_2$  is obtained by expansion of the compressed liquid which is cooled by evapn. of an external cooling agent such as  $NH_3$  in an app. which is described. Cf. C. A. 23, 2790.

**Solidifying carbon dioxide.** DRYICE CORP. OF AMERICA. Brit. 302,070, Jan. 17, 1928. An app. is described in which  $CO_2$  is obtained as snow by releasing the pressure on compressed liquid  $CO_2$ . Cf. C. A. 23, 3056.

**Apparatus for supplying carbon dioxide in liquid or solid form by use of solid carbon dioxide.** H. DEHOTTAU. Brit. 301,764, Aug. 30, 1927. Structural features.

**Storing liquid carbon dioxide.** DRYICE CORP. OF AMERICA. Brit. 302,782, Nov. 15, 1927. A definite wt. of solid  $\text{CO}_2$  is placed in a container which is then hermetically sealed. Structural features of a receptacle for this purpose are described.

**Carbon monoxide.** W. C. ARSEM (to Commercial Solvents Corp.). U. S. 1,719,867, July 9. A mixt. of  $\text{CO}_2$  and H is heated rapidly to  $1000\text{--}1200^\circ$  in the presence of a catalyst and the gaseous mixt. is then cooled rapidly to below  $100^\circ$ , condensed water is removed and rapid alternate heating and cooling is continued for the further production of CO.

**Ammonia synthesis.** I. G. FARBENIND. A.-G. Brit. 302,620, Sept. 17, 1927. Waste gases from the destructive hydrogenation of carbonaceous materials are used in  $\text{NH}_3$  synthesis after conversion of their hydrocarbon content into H and purification, which may include removal of S compds. and conversion of CO into  $\text{CO}_2$ , followed by removal of the  $\text{CO}_2$ .

**Ammonia synthesis.** WALTER H. KNISKERN (to Atmospheric Nitrogen Corp.). U. S. 1,721,455, July 16. In an app. comprising an  $\text{NH}_3$  converter, a heat-exchange system and a refrigerating system for liquefying the  $\text{NH}_3$  produced in the converter, a temp.-reducing device in which the cooling medium is at prevailing natural temps is interposed between the heat-exchange system and the refrigerating system in the gas line leading from the former to the latter and anterior to its entrance into the latter for removing low-temp. heat from the gas in the line at this point. Various details of app. arrangement are described. Cf. C. A. 23, 1479.

**Ammonia synthesis.** HANS HARTER. Ger. 478,455, Feb. 24, 1924. A no. of units for the manuf. of  $\text{NH}_3$  by combined high- and low-pressure synthesis are arranged in parallel to form a battery, and 2 or 3 such batteries are arranged in series. The gases from the first battery are united prior to removing  $\text{NH}_3$  by water-cooling, and the residual gases are passed to the next battery. Cf. U. S. 1,570,485 (C. A. 20, 802).

**Ammonia synthesis.** GASVERARBEITUNGSGESELLSCHAFT M.B.H. Fr. 656,963, July 3, 1928. See Brit. 293,361 (C. A. 23, 1726).

**Gases for ammonia synthesis.** SOC. D'ÉTUDES MINIERES ET INDUSTRIELLES. Brit. 302,306, Dec. 14, 1927. The gases are purified from O or from oxidizable impurities such as CO and  $\text{C}_2\text{H}_2$  and other hydrocarbons and reducible impurities such as S and P compds. by passage (at a temp. not exceeding  $600^\circ$ , except with N) over wood charcoal or similar carbonaceous material. A small quantity of water vapor must be present and O or air or H may be added as necessary, and pressure may be employed. The conversion products formed from the original impurities are removed by suitable absorption agents of which examples are given.

**Apparatus for ammonia synthesis.** RUDOLF ROHDE. Ger. 478,313, Nov. 12, 1924

**Oxidation of ammonia.** E. I. DU PONT DE NEMOURS AND CO. Fr. 657,467, July 12, 1928. An alloy of Pt, resistant to high temps., is used as a catalyst of the oxidation of  $\text{NH}_3$ , e. g., Pt-Rh alloys contg. 2-50% of Rh, preferably 5-25%. Other metals with a f. p. sufficiently high to increase the amt. of  $\text{NH}_3$  transformed and to diminish the loss of catalyst may also be used.

**Inorganic halides.** NAAMLLOOZE VENNOOTSCHAP ELECTROCHEMISCHE INDUSTRIE. Brit. 302,927, Dec. 22, 1927. Mixts. of oxides or oxygenated compds. (such as Ca phosphate, barytes or bauxite) with a reducing agent such as C are subjected to the action of a free halogen such as Cl at  $200\text{--}1000^\circ$ . The reaction may be promoted by agitation or by use of actinic rays.

**Purifying metallic salts.** I. G. FARBENIND. A.-G. Fr. 656,928, June 28, 1928. Salts, such as  $\text{ZnCl}_2$ , which have been used in textile, paper or other industries are freed from org. substances by treating with O under pressure at temps. above  $130^\circ$ .

**Metal carbonyls.** I. G. FARBENIND. A.-G. Brit. 301,778, Sept. 5, 1927. See Fr. 652,594 (C. A. 23, 3547).

**Alkali metal cyanides.** I. G. FARBENIND. A.-G. Brit. 301,565, Sept. 6, 1927. Fr. 656,810, June 29, 1928. Cyanides are formed by the action of  $\text{NH}_3$  and CO at temps. of  $400\text{--}800^\circ$  upon alkali metal hydroxides, oxides or salts such as  $\text{Na}_2\text{CO}_3$ , formate, acetate or sulfate, etc. Inert fillers such as MgO and catalysts such as Fe cyanides may be present. Diluent gases may also be added and the reaction may be carried out under pressure.

**Alkali and ammonium phosphates.** I. G. FARBENIND. A.-G. (Otto Schliephake and Friedrich Henning, inventors). Ger. 478,387, Feb. 22, 1928. The reaction between  $\text{CaHPO}_4$  and the bisulfate of an alkali metal or  $\text{NH}_4$  is effected by heating a mixt. of the solid reagents to a moderate temp. not exceeding the sintering temp. The

product is extd. with water and the soln. worked up in known manner. Cf. *C. A.* 23, 2790.

**Decomposition of alkaline earth metal chloride and sulfates in molten form by steam.** JULIUS KERSTEN. U. S. 1,721,485, July 16. Carbonaceous material and a fusible substance such as rock salt are added to the material under treatment such as  $\text{MgCl}_2$ ,  $\text{MgSO}_4$  or  $\text{CaSO}_4$  and the mixt. is melted by blowing in heating gases, and superheated steam is blown through the molten mass.

**Reduction of alkaline earth sulfates.** SALZWERK HEILBRONN A.-G., THEODOR LICHTENBERGER and KONRAD FLOR. Ger. 478,310, May 9, 1925. The sulfate is dissolved in fused  $\text{NaCl}$  and reduced with coke. When reduction is complete, the  $\text{NaCl}$  is decanted off from the melt and the alk. earth sulfide is then worked up.

**Mercury salts.** HUGH S. REID and AYLMER H. MAUDE (to Canadian Electro Products Co.). U. S. 1,721,188, July 16. In forming  $\text{Hg}$  salts such as sulfates, metallic  $\text{Hg}$  is treated with a strong non-oxidizing inorg. acid such as  $\text{H}_2\text{SO}_4$  in the presence of  $\text{HNO}_3$  and  $\text{O}$  is supplied to regenerate  $\text{HNO}_3$  while maintaining a temp. between  $20^\circ$  and  $80^\circ$ .

**Nitrophosphates.** ELEKTRIZITÄTSWERK LONZA. Fr. 657,288, July 11, 1928. Nitrophosphates with better powdering properties are prepd. by treating crude phosphates with  $\text{HNO}_3$  the water content of which is not sufficient to form tetraaquanitrates. The reaction is carried out at a low temp. and then with more intense heating. Ordinary nitrophosphates may be dehydrated at a temp. below  $40^\circ$ , or they may be fused and then powd. A small amt. of urea (not more than 2%) may be added to nitrophosphates to avoid formation of oxides of  $\text{N}$ .

**Colloidal dispersions of phosphates and arsenates.** AUGUST CHWALA. Ger. 478,190, Apr. 8, 1928. Phosphates and arsenates of the alk. earth and heavy metals are dispersed colloiddally in water by mech. disintegration in the presence of a protective colloid and of an alkali metal salt of an arsenic or phosphoric acid other than the ortho acid. Examples are given.

**Sodium-nitrogen compounds.** DEUTSCHE GOLD UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Fr. 656,614, June 28, 1928. See Brit. 293,040 (*C. A.* 23, 1418).

**Treatment of chlorinated zinc products or residues.** L. GRANGE. Belg. 355,843, Dec. 31, 1928. Double decompn. is effected between the  $\text{Zn}$  chloride or oxychloride and an alk.-earth hydrate or hydroxide so as to obtain insol.  $\text{Zn}(\text{OH})_2$  in the soln. of the corresponding alk.-earth chloride, which is eliminated by washing.

**Zinc salt solutions.** METALLGES. A.-G. (formerly Metallbank und Metallurgische Ges. A.-G.). Brit. 302,924, Dec. 23, 1927. Treatment of crude oxide-contg. materials with acid is effected so that any local excess of acid with respect to the  $\text{ZnO}$  content of the material is avoided, in order to minimize dissolving of impurities.

**Apparatus for obtaining divided alumina.** ELEKTRIZITÄTSWERK LONZA. Fr. 34,047, Sept. 10, 1927. Addn. to 639,645 (*C. A.* 23, 592). An app. is described for obtaining divided  $\text{Al}_2\text{O}_3$  in which dispersed or pulverized molten  $\text{Al}_2\text{O}_3$  is forced by gas under pressure through a shower of water before bringing it into a vessel of cooling water. Cf. *C. A.* 23, 3057.

**Alumina.** JULIETTE SKAPPEL NÉE WILHELMSSEN. Fr. 656,677, May 11, 1928. See Brit. 290,586 (*C. A.* 23, 946).

**Aluminum oxide.** S. I. P. SOCIETÀ ITALIANA POTASSA. Fr. 657,444, July 12, 1928. Chemically active anhyd.  $\text{Al}_2\text{O}_3$  is obtained by heating hydrated  $\text{Al}$  salts at a low temp. ( $140$ – $180^\circ$ ), such as the chloride or nitrate. The  $\text{Al}_2\text{O}_3$  may be used for the producing of  $\text{Al}$  or  $\text{Al}_2(\text{SO}_4)_3$ .

**Heavy granular concentrates from dilute solutions such as aluminum sulfate.** ARTHUR B. JONES (to Industrial Associates, Inc.). U. S. 1,721,452, July 16. The dil. soln. is subjected to spray drying to obtain light solids, these solids are liquefied (suitably by admixture with dil. soln.) and the liquefied solids are dispersed in a solidifying atm. An app. is described.

**Ammonium vanadate, etc.** J. A. WEIL, H. RAWLINSON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 302,129, July 3, 1928.  $\text{NH}_4$  vanadate is purified by forming from it an approx. satd. aq. soln., removing undissolved impurities, and repptg. by adding an  $\text{NH}_4$  salt such as the nitrate which yields non-reducing gaseous products on thermal decompn. The purified material is suitable for making  $\text{V}_2\text{O}_5$  for use as a catalyst. Various details are described.

**Barium oxide.** CHEMISCHE FABRIK SIESEL G.M.B.H. Ger. 478,166, Feb. 26, 1925. Addn. to 431,617. A mixt. of  $\text{BaCO}_3$  and  $\text{C}$  is heated in a furnace, without stirring, by radiant heat from elec. heaters, and a pressure only slightly below that of the atm. is maintained in the furnace. A porous product is so obtained.

**Carbon disulfide emulsions.** I. G. FARBENIND. A.-G. Brit. 301,561, Sept. 6, 1927. Aq. emulsions of  $\text{CS}_2$  are prepd. by use of an alc. (preferably  $\text{AmOH}$  or  $\text{BuOH}$ ) and soap.

**Apparatus for making carbon disulfide.** I. G. FARBENIND. A.-G. (Eberhard Legeler and Hermann Kob, inventors). Ger. 478,378, June 1, 1927. See Brit. 291,382 (C. A. 23, 1481).

**Chromium oxide.** I. G. FARBENIND. A.-G. Brit. 302,178, Dec. 10, 1927. A chromate or dichromate is caused to react with red P in a quantity insufficient for the formation of appreciable amts. of Cr phosphates (suitably by igniting a mixt. of the reacting materials). K phosphate or the like which may be present in the product is leached out, leaving Cr oxide as a residue.

**Litharge and minium.** RICARDO SANZ CARRERAS. Fr. 656,937, July 8, 1928.  $\text{PbCO}_3$  obtained by electrolysis is decomposed and oxidized, in a 2-floor furnace, to litharge in the upper and from thence to minium in the lower.

**Potassium phosphate.** ÉDOUARD URBAIN. Fr. 656,525, Nov. 10, 1927. An  $\text{NH}_4\text{-K}$  phosphate ( $\text{NH}_4\text{KHPO}_4$ ) is produced by dissolving  $\text{KPO}_3$  in a soln. of  $\text{NH}_3$ .

**Sodium hypochlorite.** MALCOLM P. APPELEBEY and CHARLES CARTER. Fr. 656,653, Apr. 6, 1927. See Brit. 274,197 (C. A. 22, 2036).

**Trisodium phosphate.** SOC. DES. PHOSPHATES TUNISIENS. Fr. 656,905, July 2, 1928. A cryst. compn. contg.  $\text{Na}_3\text{PO}_4$  and  $\text{NaCl}$  is obtained by dissolving  $\text{H}_3\text{PO}_4$ ,  $\text{Na}_2\text{CO}_3$ ,  $\text{NaCl}$  and  $\text{NaOH}$  in water and cooling, or by neutralizing  $\text{H}_3\text{PO}_4$  with  $\text{Na}_2\text{CO}_3$ , filtering and adding  $\text{NaCl}$  and  $\text{NaOH}$  to the  $\text{Na}_2\text{HPO}_4$  formed.

**Purification of sodium sulfide.** SOCIÉTÉ INDUSTRIELLE DES APPLICATIONS CHIMIQUES I. N. D. A. C. Belg. 356,203, Dec. 31, 1928. The  $\text{Na}_2\text{S}$  is mixed with  $\text{NaOH}$  soln., treated in an autoclave with steam under pressure, and the soln. is decanted, filtered, concd. and crystd.

**Zinc oxide.** LACKWERKE JAPONIKA G.M.B.H. Ger. 467,588, July 11, 1926. Processes of the kind known for burning coal dust are applied to Zn dust, which is burnt directly in a stream of air. The continuous use of an auxiliary source of heat is dispensed with.

**Magnesia.** SALZBERGWERK NEU-STASSFURT. Brit. 301,751, Dec. 3, 1927. Burnt dolomite is treated with an  $\text{NH}_4$  salt such as  $\text{NH}_4\text{Cl}$  to extract the lime content as a sol. salt. Waste liquors from the Solvay soda process or from the treatment of  $\text{Mg NH}_4$  carbonate with  $\text{KCl}$  may be used for the extrn.

**Bleaching powder.** SOC. ELETTRICA ED ELETTROCHIMICA DEL CAFFARO, ACHILLE CARUCHI and CARLO PAOLONI. Fr. 654,149, May 12, 1928. Bleaching powder contg. more than 40% active  $\text{Cl}$  is prepd. by the action of  $\text{Cl}$  on  $\text{Ca(OH)}_2$  suspended in an inert liquid such as  $\text{CCl}_4$  which dissolves neither the  $\text{Ca(OH)}_2$  nor the bleaching powder, the  $\text{Ca(OH)}_2$  being ground in the liquid before or during the reaction. It may be obtained cryst. by reacting above  $40^\circ$  and then cooling below  $20^\circ$ .

**Dehydrating and dehydrogenating catalysts.** E. I. DU PONT DE NEMOURS AND Co. Fr. 657,505, July 13, 1928. Substances which modify or control the dehydrating and dehydrogenating action of catalysts on org. compds. are incorporated with the catalysts. Substances modifying the dehydrating action are oxides alk. under the conditions of working, and substances modifying the dehydrogenating action are oxides acid under the conditions of working. Thus, in the production of acetone from iso- $\text{PrOH}$  the amt. of propylene formed is greatly reduced by adding 4.5% of  $\text{Na}_2\text{CO}_3$  to the  $\text{ZnO}$  catalyst. If 7% of  $\text{ZnSO}_4$  is added instead of  $\text{Na}_2\text{CO}_3$  the amt. of propylene formed is greater than the amt. of acetone. In passing  $\text{EtOH}$  over  $\text{U}$  oxide, if  $\text{K}_2\text{CO}_3$  is added to the catalyst 10 mols. of  $\text{AcH}$  are formed for 1 mol. of  $(\text{CH}_3)_2$ , but if the  $\text{K}_2\text{CO}_3$  is replaced by 15% of  $\text{H}_3\text{BO}_3$  only 0.09 mols. of  $\text{AcH}$  are formed for 1 mol. of  $(\text{CH}_3)_2$ .

**Catalysts for oxidizing sulfur dioxide, etc.** B. LAMBERT and NATIONAL PROCESSES, LTD. Brit. 301,853, Sept. 6, 1927. Catalysts are obtained by permitting a Cr oxide hydrogel to absorb an insol. or slightly sol. base (suitably by use of acetates of Ca, Mg, Ni, Co, Mn and Zn).

**Catalytic production of oxygenated carbon compounds.** W. A. LAZIER. Brit. 301,806, June 12, 1926. Catalysts for use in reactions such as that of  $\text{CO}$  with  $\text{H}$  or steam or in dehydrogenation of compds. such as  $\text{EtOH}$  are prepd. by heating to decomn. a double chromate of a nitrogenous base such as  $\text{NH}_4$ , or pyridine and one of the metals Zn, Cu, Cd, Mg, Mn, Ag and Fe. The catalysts may be rendered more active by leaching with a "weak" acid such as 5-10%  $\text{HOAc}$ . Examples are given of the production of  $\text{MeOH}$  and higher alcs. from  $\text{CO}$  and  $\text{H}$ . Prepn. of basic Zn  $\text{NH}_4$  chromate, Mn  $\text{NH}_4$  chromate and Zn bichromate tetrapyridine is described.

**Reactivating catalysts used for removing nitrogen oxides from hydrogen mixtures.** Soc. L'AIR LIQUIDE, Soc. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS G. CLAUDE. Brit. 301,736, Dec. 3, 1927. Regeneration of catalysts used in processes such as described in Brit. 287,577, (C. A. 23, 488) is effected by washing them with a dil. alk. soln. such as one contg.  $\text{NH}_3$  and its compds. and used for decarbonating the gas mixt. under treatment.

**Catalytic production of hydrogen.** I. G. FARBENIND. A.-G. Brit. 301,969, Sept. 15, 1927. Catalytic conversion of mixts. of hydrocarbons with water vapor or  $\text{CO}_2$  into H and CO is effected in elongated chambers in which the catalyst is indirectly heated to 600–1000°. The reaction mixt. is preferably preliminarily freed from S compds. by passing over heated metallic oxides. An app. is described.

**Separation of oxygen from a mixture.** G. LIBBRECHT. Belg. 355,396, Dec. 31, 1928. The mixt is brought into contact with a compd. which can be easily oxidized and de-oxidized under the influence of a variation in the surrounding medium; *e. g.*, the mixt. is brought into contact with animal hemoglobin which combines with the  $\text{O}_2$ , and the reaction product is subjected to vacuum to liberate the absorbed  $\text{O}_2$ .

**System of mining sulfur by fusion.** WILBER JUDSON (to Texas Gulf Sulphur Co.). U. S. 1,719,981, July 9. In the treatment of partially exhausted underground S deposits, a pressure is maintained in the deposit by withdrawing water from the cold lower portion of the deposit and withdrawing hot water from the upper portion of the deposit and reintroducing the withdrawn hot water into the deposit.

**Sulfur burner operation.** EDWIN J. MULLEN (to General Chemical Co.). U. S. 1,720,742, July 16. S is distd. under such conditions as to form a gas consisting substantially of S vapor without  $\text{SO}_2$  and the S vapor is burned in heat transfer relation to the S undergoing distn.  $\text{SO}_2$  is thus produced which is substantially free from impurities originally present in the S. An app. is described.

**Carbon.** LOUIS GUMZ. Ger. 477,508, Mar. 23, 1927. App. is described for producing graphite-like C from natural gas by pyrogenic decompn. Cf. C. A. 23, 2539.

**Active carbon.** METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 302,774, Nov. 1, 1927. Fine-pore vegetable materials such as plum stones, coconut shells, and other hard shells, broken into small pieces, are heated with a concd.  $\text{ZnCl}_2$  soln. (suitably contg. about 70% as much  $\text{ZnCl}_2$  as the wt. of the material treated). The mixt. is dried at about 200° and then heated to 700°, the  $\text{ZnCl}_2$  is extd. with HCl and water and the residue is dried, broken up and sieved.

**Active charcoal.** LA CARBONISATION (Soc. générale d'exploitation des carbonnes). Fr. 657,545, Nov. 24, 1927. Decolorizing active charcoal is made by solubilizing the salts contained in the charcoal by treating with  $\text{MgCl}_2$ , then with HCl or  $\text{HNO}_3$  or a mixt. thereof, afterward solubilizing the hydrocarbons of the charcoal by treatment with NaOH or carbonates, drying and heating to 400–500°, washing with water and heating to 500–1500° in the absence of air.

**Reactivating decolorizing carbon.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Ger. 478,311, Jan. 23, 1926. See Brit. 264,799 (C. A. 22, 307).

**Silica gel.** KUNO WOLF and MAX PRAETORIUS. Ger. 478,312, Sept. 27, 1927. Streams of concd. acid and concd. waterglass soln. are continuously discharged from tanks so that the waterglass soln. stream surrounds the acid stream. The gelatinous product falls on to and is disintegrated by rollers, from which it is removed and worked up in the usual way.

**Plastic material.** JACQUES POBEREJSKY. Fr. 656,760, Nov. 15, 1927. Articles are molded under heat and pressure from a mixt. of powd. ebonite and a powd. resin such as bakelite.

**Plastic compositions.** J. C. PATRICK and N. M. MNOOKIN. Brit. 302,270, Dec. 13, 1927. Products sol. in  $\text{CS}_2$  but insol. in most org. solvents and which may be made to resemble either hard or soft rubber are obtained by reaction between halogen addn. compds. of olefins such as ethylene or propylene dichloride and dibromides and sol. polysulfides such as those of the alkali metals, alk. earth metals and  $\text{NH}_3$ . The reaction is promoted by heating but may be effected at ordinary temp.

**Plastic compositions containing cellulose esters or ethers, etc.** I. G. FARBENIND. A.-G. Brit. 302,615, Sept. 12, 1927. Plastic compns. and lacquers are formed with nitrocellulose or other cellulose esters or ethers and various other substances such as solvents, graphite, talc, mica, asbestos, slag wool, wood, cork, brown coal, millet, coconut fiber, tapioca, maize, lithopone, white lead, powdered slate, pumice, kieselsguhr, chalk, resins, plasticizers and coloring substances. Brit. 302,616 specifies "knifing compns." of somewhat similar character contg. over 3 times as much of a filler such

as kieselguhr, powdered pumice or levigated chalk as the quantity of nitrocellulose or other cellulose deriv. used in the compn. Cf. *C. A.* 23, 2540.

**Plastic composition containing a phenolic aldehyde condensation product.** ROBERT A. NORTON (to Selden Co.). U. S. 1,720,051, July 9. A compn. which is readily machined and given a high polish is formed from a phenol-aldehyde condensation product, initially fusible and capable of being hardened by heat, homogeneously mixed with Bu palmitate, Am stearate or other suitable ester of a "polybasic" aliphatic acid and alcs having less than 3 OH groups.

**Artificial [condensation] substances.** HANS KAPPELER. Fr. 657,477, July 13, 1928. See Brit. 293,872 (*C. A.* 23, 1729).

**Non-turbid aldehyde condensation products.** ROBERT A. NORTON (to Selden Co.) U. S. 1,720,052, July 9. In producing hard, infusible, relatively non-turbid aldehyde condensation products, reaction in the presence of an alk. condensing agent such as  $\text{Na}_2\text{CO}_3$  is effected between an aldehyde, e. g.,  $\text{CH}_2\text{O}$ , and a "resinophoric compd." such as phenol capable of reaction to produce a resin that can be hardened by heat, a polycarboxylic acid compd. such as Na phthalate is added, free water is substantially removed, and the product is then hardened by heating.

**Phenol-aldehyde condensation products.** I. G. FARBENIND. A.-G. Brit. 302,600, July 14, 1927. Products which may be rendered infusible and insol. by heat and pressure are obtained by condensing phenols with aldehydes such as  $\text{CH}_2\text{O}$  in the presence of compds. such as butylamine, mono- or di-ethanolbutylamine, cyclohexylamine, di cyclohexylamine, cyclohexylethanolamine or dicyclohexylethanolamine in small quantities.

**Urea-formaldehyde condensation products.** KUNSTHARZFABRIK F. POLLAK GES. Brit. 301,798, Dec. 5, 1927. Transparent products from carbamides and aldehydes contg. no free aldehydes may be obtained by condensing less than 2 mols aldehyde in acid soln. with 1 mol. of the amide under such conditions as to maintain some free aldehyde in the reacting mixt. at all stages of the reaction. Various details of procedure are given. Cf. *C. A.* 23, 1729.

**Urea-formaldehyde condensation products.** POLLOPAS, LTD., E. C. C. BALY and E. J. BALY. Brit. 301,626, Nov. 11, 1927. Vitreous and transparent condensation products are obtained by condensing dimethylolurea having a m. p. of at least  $134^\circ$  (which may be obtained by the method described in Brit. 299,487 (*C. A.* 23, 3236)) The condensation may be effected by boiling under reflux an aq. soln. of a  $p_H$  between 5 and 7. Various details are given.

**Forming tubes, sheets, etc., from mica flakes and varnish containing a phenol-urea-aldehyde condensation product.** A. LLOYD and BAKELITE, LTD. Brit. 302,612, Aug. 15, 1927.

**Molded telephone transmitters of phenolic condensation product with metal inserts.** FREDERIC S. KOCHENDORFER (to Western Electric Co.). U. S. 1,720,681, July 16 Structural features.

**Rubber-bonded dry molding compositions.** W. B. WESCOTT (to Rubber Latex Research Corp.). Brit. 302,151, Dec. 10, 1927. Granular or fibrous fillers are treated with dild. latex contg. a protective colloid such as hemoglobin, and preferably  $\text{ZnO}$ , and the mass (which may contain as little as 5% rubber) is dried and comminuted or shredded. Various substances such as asbestos, cotton, comminuted old tire material, whiting, talc, and S and accelerators may be added. Numerous details are described.

**Molding casein.** P. HAESSLER. Brit. 302,545, May 21, 1928. An app. is described in which casein powder under high pressure is forced through a sieve to render it plastic and then injected through a nozzle into a mold. The casein may be heated to  $90\text{--}110^\circ$  as it is charged into the app.

**Adhesive and impregnating compositions.** I. G. FARBENIND. A.-G. Brit. 302,710, Sept. 17, 1927. Stearin pitch, cotton-oil pitch or wool-fat pitch or similar materials are heated with animal or vegetable oils and S or S-yielding substances and S-bearing compds. extd. from tar with solvents are added. Cf. *C. A.* 22, 4214.

**Adhesive paper or fabric.** I. G. FARBENIND. A.-G. Brit. 302,588, Dec. 17, 1927. One side of the material is coated with gum or rubber and the other side with cellulose laurate or other ester, mixed ester or ether-ester of cellulose with a higher aliphatic acid. The latter facilitates unrolling by preventing sticking.

**Adhesives containing cellulose esters.** W. PLINATUS (to Compagnie française d'exploitation des procédés Plinatus). Brit. 302,324, Dec. 14, 1927. Dry adhesives (suitable for use in joining materials together under the action of pressure and heat) comprise cellulose esters such as nitrocellulose contg. a solvent of high b. p. in a state

of fine distribution in the compn., with or without addnl. substances such as resins. The adhesive may be used as a powder or foil.

**Plastic stone-like composition made with vegetable ivory and magnesium oxychloride cement.** E. TELTSCHIK & Co. Brit. 301,893, Dec. 9, 1927. Ground vegetable ivory is treated with dil. acid or alk. soln., washed with water, dried, satd. with  $MgCl_2$  soln. and  $MgO$  is added. Waterproofing substances such as solns. of rubber, celluloid, or synthetic resin and coloring matter may be added.

**Cement.** BURR W. TUTTLE. U. S. 1,719,914, July 9. A cement which is suitable for repairing ceramic ware comprises asbestos 2 and  $ZnO$  1 part mixed with sufficient waterglass to form a thick paste.

**Cement crystallization vessel.** ARTHUR WILHELMI. Ger. 477,669, Nov. 17, 1925. Details of construction and arrangement are given.

**Acoustic diaphragms.** W. J. RICKERS. Brit. 302,746, Oct. 1, 1927. A diaphragm of paper, linen, silk, artificial silk, mercerized cotton or like material is treated with a synthetic condensation product of urea, thiourea or their compds.

**Diaphragms for telephones, etc.** ROBERT REINERT. U. S. 1,721,038, July 16. A disk of metal such as Al alloy of the desired final shape is placed between 2 blocks which may be formed of iron and which conform to the shape of the surfaces of the diaphragm and subjected to heating and then to slow cooling to remove internal stresses of the metal of the diaphragm due to the mechanical operations in its manuf.

**"Bakelite" diaphragms for "loudspeakers," etc.** W. K. WEBSTER. Brit. 302,459, Nov. 2, 1927. Structural features.

**Brake drums.** VINCENT BENDIX (to Bendix Brake Co.). U. S. 1,720,815, July 16. A Cr surface coating is cemented to a drum of ferruginous metal, in order to increase strength and lessen corrosion.

**Brake drums.** RAYMOND J. NORTON (to Bendix Brake Co.). U. S. 1,720,853, July 16. Drums of ferruginous metal are provided with an exterior coating of material of greater heat conductivity such as by calorizing with Al which serves to facilitate dissipation of heat.

**Brake lining material.** W. B. WESCOTT (to Rubber Latex Research Corp.). U. S. 1,720,407, July 9. An integral body of gelled rubber derived *in situ* from latex is permeated with asbestos fibers and reinforced with wire.

**Curing friction material suitable for brake or clutch facings.** ELMER R. ROSS (to Raybestos Co.). U. S. 1,721,135, July 16. A material with a base of asbestos fiber is treated with a primarily liquid binder such as a soln. of gilsonite in gas oil and then cured by heating in a liquid medium such as molten type metal substantially incompatible with the binder at a temp. below that which would carbonize the base, at a temp. sufficiently high to uniformly cure and harden the binder.

**Stencil sheet.** RICHARD DAMME. U. S. 1,719,926, July 9. Stencil sheets are prepd. with a compn. comprising collodion, oleic acid, lithopone, soap, castor oil, glycerol,  $AmOAc$  and a dye.

**Dry stencil.** HENRY H. HAWLING. U. S. 1,720,897, July 16. A base such as paper is treated with a compn. comprising casein, an alkali hydroxide and Na tungstate.

**Impregnated paper for recording impressions by electric currents.** R. POLLAK-RUDIN. Brit. 301,749, Dec. 3, 1927. A paper strip is impregnated with a portion only of the components forming the substance for chemical reaction and necessary ions for the reaction are derived from one or more electrodes used. Among the materials suitable for such use together are: dimethylglyoxime and Ni; tannin and Fe;  $NH_4$  molybdate and Mo. Org. dyes of their leuco compds. also may be used and reaction with them effected by O or H ions evolved at the electrodes. Various details and modifications are described.

**Preventing condensation on glass or other polished surfaces.** F. W. WELCH. Brit. 301,585, Sept. 24, 1927. The surface is rubbed with a mixt. formed from soap 16, glycerol 1 and water 24 parts. The soap and water are boiled together and then cooled and reheated before adding the glycerol.

**Rendering containers or wrappings of paper or cloth impermeable.** W. DAUWITZ. Brit. 301,861, Dec. 7, 1927. Coating is effected by use of hardened oils or fats such as hardened coconut oil, peanut oil or train oil (suitably after a preliminary impregnation with glue, gelatin, cellulose, cellulose esters or like materials).

**Liquid containers.** I. G. FARBENIND. A.-G. Fr. 657,440, July 12, 1928. Containers for liquid air or O have several walls between which adsorbents such as active  $SiO_2$  are placed to create a vacuum between these walls.

**Composition for polishing metals.** F. HAIGH. Brit. 302,423, Sept. 29, 1927.

Flaked stearin 2, coconut oil 1, peanut oil 1, tripoli powder 4, "polishing earth" 4, paraffin oil 1 and "petrol" 1 part.

**Treating silverware with mercury vapor.** DANIEL GRAY, RICHARD O. BAILEY and W. S. MURRAY (to Onaida Community, Ltd.). U. S. 1,720,215, July 9. Treatment of the ware with Hg vapor is effected in an atm. free from O or other reagents which would interfere with the absorption of the Hg by the ware. U. S. 1,720,216 specifies silver-plated ware in which the plating consists of an intimate mixt. of Ag and Hg with a Ag content of about 90% or more.

**Printing with non-drying inks.** JACOB E. HYDEMAN. U. S. 1,721,397, July 16. In printing an absorbent paper that may be used at once, a non-drying ink is used in the intaglio printing process.

**Stereotype mats.** ARLIE W. SCHORGER (to C. F. Burgess Laboratories, Inc.). U. S. 1,720,243, July 9. Stereotype dry mats are made of fibrillated  $\alpha$ -cellulose mixed with a filler such as clay.

**Shoe-stiffening material.** W. J. LUND and LUCIEN P. MELLERIO (to Celastic Corp.). U. S. 1,720,795, July 16. A gelatinizable stiffening substance in fibrous form such as cellulose acetate is used in making stiffener blanks which may be softened with a solvent. Cf. C. A. 23, 3316.

**Apparatus for generating gas such as hydrocyanic acid for killing rodents in burrows.** HARRY C. ELKINS. U. S. 1,720,321, July 9.

**Cleaning the bore surfaces of firearms.** WILBERT J. HUFF. U. S. 1,719,933, July 9. The bore surfaces are treated with a free-flowing non-corrosive aq. emulsion contg. a large proportion of water together with an oil phase such as lard oil and light lubricating oil and a peptizing agent, e. g.,  $\text{NH}_4$  oleate, and the liquid and assoc. materials are removed by swabbing.

**Fireproofing.** SOC. LEMERCIER FRÈRES. Fr. 656,693, June 1, 1928. Ammonium phosphate alone or with Na stannate is used for fireproofing. Fr. 656,694 describes a process by which fireproofing substances are crystd. in the cloth.

**Fireproofing and fire-extinguishing compositions.** I. G. FARBERIND. A.-G. Brit 302, 172, Dec. 10, 1927. A small quantity of an alkylated or aralkylated sulfonic acid or water-sol. salt of such an acid such as Na butylnaphthalene sulfonate or  $\text{NH}_4$  benzyl-naphthalene sulfonate is used with other substances such as Al sulfate and  $\text{NaHCO}_3$ ,  $\text{NH}_4\text{Cl}$  or  $\text{CCl}_4$ .

## 19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

**The glass industry in North America.** W. E. S. TURNER. *Pottery Gaz.* 54, 927-33 (1929); cf. C. A. 23, 4032.—The production and sale of various kinds of glass and glassware are discussed. T. includes in his discussion the use of Ba sulfate in the glass batch, effective mixing of the batch, care with the cullet, glass pots and pot furnaces, furnace design and glass-forming machines as used in American glass manuf.

R. A. HEINDL

**Chemical glassware manufactured by the Russian governmental plant "Druzhnaya Gorka."** V. E. TISHCHENKO. *Zhur. Prikladnoi Khim.* 2, 3-19 (1929).—Chem. resistivity of this glass is superior to any other grade of chem. glass manufactured in other countries, though it is less resistant to heat than Jena glass and especially Pyrex.

V. KALICHEVSKY

**Coloring of glass by bismuth.** II. KITSUZO FUHA. *Mazda (Japan)* 3, 295-324 (1928); cf. C. A. 23, 1731 (1929). (In English.)—Basic Bi carbonates and Bi nitrates added to glass or porcelain produce a color that depends upon the compn. of the glass. Upon heating, the glass turns deep brown, gray or milk-white. With  $\text{KNO}_3$  as oxidizing agent, the color is light and its nuance depends upon the compn. of the glass. If K tartarate is used as the reducing agent, no marked color is obtained. With arsenious acid the coloration is weakened, probably by the pptn. of metallic Bi.

K. SOMEYA

**Coloring incandescent lamps on the inner surface.** A. F. LINDSTROM. *Chem. Mat. Eng.* 36, 410-1 (1929).

E. H.

**Flocculation action of hydrophilic sols on suspensions of clay, and its practical uses.** TSURUJI OKAZAWA and TERUKICHI SANO. *Bull. Inst. Phys. Chem. Research (Tokyo)* 8, 356-68; *Abstract Ed.* 2, 46-8 (1929).—Suspensions of 0.5 g. of clay in 20 cc. of solns.

ranging from 0.0002 *N* NaOH to 0.002 *N* HCl were treated with gelatin sol to give from 0.025% to 0.00005% gelatin and the state of flocculation was observed after vigorous shaking and 30 sec. standing. With NaOH stronger than 0.0002 *N* no flocculation was obtained, while flocculation was complete in neutral soln. with 0.005 and 0.0025% gelatin. Casein, albumin, gum arabic and starch give very small flocculation values, while a sol of "Konnyaku-ko" (a powder obtained from the root of devil's tongue) gives enormously high values. Concns. as low as 0.0025% Konnyaku-ko gave complete flocculation between 0.0002 *N* NaOH and 0.002 *N* HCl, while with 0.00005% Konnyaku-ko complete flocculation of a clay suspension is obtained in acid soln. This flocculation of clay suspensions aids in their filtration, a soln. of 10 g. infusorial earth in 450 cc. of 30% raw sugar soln. requiring 150 min. for filtration with no gelatin sol present and only 90 min. on the addition of 4 cc. of 1% gelatin sol.

H. STOERTZ,

**Quality of Endai fire clays.** MASAJI KAJIWARA. *J. Japan Ceram. Assoc.* 36, 58-65(1928).—Endai grog clay is a very compact shale with an oily feel. It is vitrifiable and melts at cone 34. It contains SiO<sub>2</sub> 42.44, Al<sub>2</sub>O<sub>3</sub> 38.41, Fe<sub>2</sub>O<sub>3</sub> 2.84, CaO 0.57, MgO 0.34%; loss on ignition is 16.48%. Grog from the clay was slag-proof, dense and smooth. Bricks rich in fine grog were excellent regardless of their porosity. In chem. compn. and refractoriness, the Endai clay resembles the best Fukushu clay, which is widely used in Japan. However, the Endai clay is finer and more plastic than the Fukushu clay.

S. KONDO

**The load test of refractories. II.** MINORU NAKAMOTO. *J. Japan Ceram. Assoc.* 36, 94-103(1928).—Expts. were made on the load-bearing property of Kokaseki, a pumice-like volcanic rock produced in Niishima, Island of Izu. A light reddish brown and a white specimen, resp., contained SiO<sub>2</sub> 78.27, 77.41; Al<sub>2</sub>O<sub>3</sub> 14.66, 13.34; Fe<sub>2</sub>O<sub>3</sub> 3.71, 2.49; CaO 1.23, 1.17; MgO 0.81, 0.77; alkalis (by diff.) 1.32, 4.82%. The specimens show no abnormal expansion in heating and behave in softening like silica brick.

S. KONDO

**The softening temperature of fire brick under load.** SEIJI KONDO. *J. Japan Ceram. Assoc.* 36, 208-17, 519-27(1928).—The softening behavior of 48 different fire brick made by 15 manufacturers under a load of 2 kg./sq. cm. has been studied. Forms of height-temp. curves, relation between the softening temp. and refractoriness, and that between softening temp. and chem. compn. are discussed.

S. KONDO

**The heat-resisting properties of bricks, tiles and cement wares.** SEIJI KONDO. *J. Japan Ceram. Assoc.* 36, 528-36(1928).—Tests were made on the refractoriness and softening behavior under a load of 2 kg./sq. cm. of common bricks, hollow tile, paving brick, wall tiles, stove tile, cement-asbestos slate and various mixtures of a portland cement and the standard sand or a sand of the Tama river. Softening temp. and curves of the cement-asbestos slate are markedly influenced by the direction of pressure. Specimens made of neat cement or portland cement and standard sand show peculiar softening curves, probably due to changes other than melting.

S. KONDO

**An example of Japanese kaolinite clays.** MINEICHI MASUDA. *J. Japan Ceram. Assoc.* 36, 433-9(1928).—A clay produced at Jishahara, near Sawatari hot spring in Shimotsuke, consists chiefly of minute kaolinite crystals and a small proportion of hydromica. It contains no colloidal kaolin. The kaolinite is mainly hexagonal plates, angle 120°, almost uniform in size, and the length of a side of the hexagon about 0.01 mm.; the crystals are almost colorless and transparent, interference color dark gray, double refraction weak,  $n_D \alpha$  1.560,  $\gamma$  1.567; hence max. double refraction is 0.007. The hydromica is fibrous and minute, though most crystals are a little larger than those of the kaolinite, almost colorless and transparent, double refraction strong,  $n_D$  1.575-1.590. The associated minerals are iron pyrites and some quartz; tourmaline and the other minerals usually accompanying kaolinite are rare. A sample, chiefly composed of kaolinite crystals and poor in iron pyrites, gave loss on ignition 14.02, SiO<sub>2</sub> 47.06, Al<sub>2</sub>O<sub>3</sub> 36.48, Fe<sub>2</sub>O<sub>3</sub> 0.93, CaO 0.36, MgO trace, alkalis (by diff.) 2.25%. The clay softens at cone 26. An x-ray photograph by the powder method is shown. No very distinct lines were obtained. Heat absorption occurring at 400° and 650°, and heat evolution occurring at 1000° and 1200° are discussed. Temp.-contraction curves of primary and secondary heatings are shown. The max. linear expansion occurring at 600° is 1.7% and shrinkage at 1330° is 11.7%.

S. KONDO

**Study of clay slip. I. Experiments on electrolytes, fluidity and hydrogen-ion concentration.** TOSAKU YOSHIOKA AND TATSUO IRIS. *J. Japan Ceram. Assoc.* 36, 312-23(1928).—Fluidity and  $p_H$  value of the clay slips are increased by the addition of alk. electrolyte within certain ranges; the action of acidic electrolyte is the reverse. The deflocculating action of Na silicate or NaOH is far stronger than that of Na<sub>2</sub>CO<sub>3</sub>.

or  $\text{NH}_4\text{OH}$ ; 0.16–0.24% of the alkalis is sufficient for the min. viscosity and the corresponding  $p_H$  value varies from 7.50 to 10.00. The fluidity is a little increased by aging. S. KONDO

**Reversible expansion of clayware.** V. TOSAKU YOSHIOKA. *J. Japan. Ceram. Assoc.* 36, 484–92(1928); cf. *C. A.* 23, 2280.—A study was made of the effect of method of prep. test pieces upon their reversible thermal expansion. VI. *Ibid.* 567–76.—Expts. were made of thermal expansion of Zettlitz kaolin, Kato kaolin and Gairome clays (plastic kaolins) of Seto, Tokiguchi and Seikirei. The curves showing the relation between temp. and linear expansion are nearly straight. Heat treatment exerts a marked effect upon the expansion. Some of the clays heated at  $1300^\circ$  or  $1400^\circ$  show an abnormal expansion at temps. under  $250^\circ$ . The curves of the clays heated at  $1500^\circ$  are practically straight and the expansions are smallest, the coeff. of expansion ranging from 0.0528 to 0.0535. S. KONDO

**Progress report on investigation of sagger clays.** V. Preparation of experimental sagger bodies according to fundamental properties. R. A. HEINDL AND L. E. MONG. *J. Am. Ceram. Soc.* 12, 457–80(1929).—Data indicate that bodies having (1) porosity of less than 25%, (2) a low modulus of elasticity, (3) as high transverse strength as is compatible with the low modulus of elasticity, and (4) low thermal expansion below  $250^\circ$ , are the most desirable. C. H. KERR

The relation of a modulus of grain size to the mechanical strength of sagger mixtures. RAYMOND E. BIRCH. *J. Am. Ceram. Soc.* 12, 451–4(1929).—Batches having the same classification modulus will give about the same fired, transverse strength. Grog mixts. having classification moduli of about 1.5 will make the strongest saggars, both dry and burned. C. H. KERR

Some absorption properties of clay bricks. L. A. PALMER. *Bur. Standards, J. Research* 3, 105–27(1929). E. H.

**The bonding of silica bricks.** W. J. REES. *Refractories J.* 4, 104–9(1929).—Of the bonds tried, lime has come into the most general use. Sol. bonds tried were Na silicate,  $\text{NH}_4$  alum,  $\text{Al}_2(\text{SO}_4)_3$  and  $\text{CaCl}_2$ ; most of these are patented for the purpose. The disadvantage of sol. bonds is that they produce a glassy skin liable to spall, with a weak core. Org. bonds have been used with some success, notably tar, dextrin, starch paste, and wood by-products. These gave no strength after burning. With lime the purer the silica the more bond is required. The  $\text{CaO}$  reacts with feldspathic impurities and  $\text{SiO}_2$  to form a  $\text{Ca-Al}$  silicate, approx.  $\text{CaO}$  23%,  $\text{Al}_2\text{O}_3$  15%,  $\text{SiO}_2$  62%. This begins to melt at  $1150^\circ$ . As the temp. rises this aids in the conversion of quartz to tridymite and cristobalite. A high % of tridymite is desirable because of the higher expansion coeff. of cristobalite. Expts. with clay for a bond showed 2% to be sufficient, but the best results were obtained with  $3\frac{1}{2}\%$  clay and 0.2% Na silicate. In com. tests clay-bonded bricks showed a slight advantage in resistance to spalling.  $\text{Fe}_2\text{O}_3$  and  $\text{P}_2\text{O}_5$  have both been used as catalysts to increase the proportion of tridymite, but their value has not been definitely established. M. A. EDDY

**The silica firebrick.** GEOFFREY W. M. REES. *Refractories J.* 4, 142–7(1929).—Both ganister and quartzite are satisfactory raw materials. Inversion changes are sluggish except in the presence of certain fluxes. Na tungstate produces a fairly rapid change. By rapid heating the inversions were prevented and the m. ps. of the forms were quartz  $1500^\circ$ , tridymite  $1670 = 10^\circ$ , cristobalite  $1710 = 10^\circ$ . Repeated burning raises the % of inversion slowly. Storage conditions affect the strength of the finished brick. Bricks exposed to the weather for 5 months showed a cold-crushing strength of 1400 lbs., covered by a roof only, 2100 lbs. and kept in a dry room 2350 lbs. per sq. in. M. A. EDDY

**Analysis of refractory materials.** II. H. J. VAN ROYEN. *Arch. Eisenhüttenw.* 2, 371–3(1928); cf. *C. A.* 22, 3082.—A report on standard methods of analysis of magnesite and its products, adopted by the German Iron Smelters Association. Moisture is detd. by drying at  $105^\circ$  for 2 hrs., except in burned products that absorb  $\text{CO}_2$ , and then the detn. is omitted. Loss on ignition is obtained by heating to bright redness in a porcelain crucible to const. wt.  $\text{SiO}_2$  is detd. by the ordinary process of double evapn. with  $\text{HCl}$ , filtering, igniting the combined residues and volatilizing  $\text{SiO}_2$  with  $\text{HF}$  and  $\text{H}_2\text{SO}_4$ . The ignited residue is then treated with  $\text{HF}$  and  $\text{H}_2\text{SO}_4$ , evapd. until  $\text{SO}_3$  appears, taken up with  $\text{HCl}$  and added to the main filtrate. The latter solu. is made up to 500 cc. and aliquot portions are taken for analysis. To det. Fe treat with  $\text{H}_2\text{O}_2$ , boil, add  $\text{HCl}$  and  $\text{NH}_4\text{CNS}$ , and titrate with  $\text{TiCl}_4$ . For  $\text{Al}_2\text{O}_3$  ppt. with  $\text{NH}_4$  phosphate soln. after reduction with  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  in  $\text{AcOH}$  soln., and weigh as  $\text{AlPO}_4$ . For  $\text{CaO}$  remove Fe, Al and Mn by pptn. with Br and  $\text{NH}_4\text{OH}$ , redissolve and reppt. twice. Finally ppt.  $\text{CaC}_2\text{O}_4$  with  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  in presence of  $\text{AcOH}$ ; redissolve and

rept., dissolve in  $H_2SO_4$  (1:4) and titrate warm ( $60^\circ$ ) with  $KMnO_4$ . To det.  $MgO$  ppt. the filtrate from  $CaC_2O_4$  with  $NH_4$  phosphate in presence of  $NH_4OH$ , shake, filter and det.  $MgO$  from weighed, purified  $Mg_2P_2O_7$ . Mn is detd. in a sep. sample by soln. in  $HCl$ , treatment with  $ZnO$ , filtration of aliquot portion, and titration of the latter (hot) in the presence of a slight excess of  $ZnO$  by means of  $KMnO_4$  (Volhard method).

W. C. EBAUGH

**Magnesite refractories.** N. H. HORN. *Chem. Eng. Mining Rev.* 21, 261-4 (1929).—The geographical distribution of magnesite, methods of calcination, the properties of caustic and dead-burned magnesite and the manuf. and properties of magnesite bricks are briefly discussed. The thermal cond. of magnesite brick is high and decreases with temp. rise. The thermal expansion at high temps. is about 1.56%.

W. H. BOYNTON

**Insulation and refractories in furnaces.** GUY A. BARKER. *Iron Age* 123, 1642-3 (1929).

DOWNES SCHAAP

**Investigations of the corrosion of refractory materials. II. Influence of the chemical composition of the slags.** HERMANN SALMANG and FRIEDRICH SCHICK. *Arch. Eisenhüttenw.* 2, 439-47 (1929).—Quant. tests were made to study the corrosive strength of slag on fireclay crucibles. The strength of the pure oxides decreases in the order:  $PbO$ ,  $FeO$ ,  $MnO$ ,  $CaO$ ,  $Fe_2O_3$ ,  $K_2O$ ,  $Na_2O$ ,  $Mn_2O_3$ . Mixts. of the oxides have a smaller influence than the pure oxides. Boric acid attacks the crucible, but  $Al_2O_3$  and  $SiO_2$  do not. Addns. of  $FeO$  and  $MnO$  to slag with high  $CaO$  contents (over 40%) increase the attack.

A. E. BEITLICH

**Optical methods as an aid to the study of refractories.** T. N. MCVAY. *J. Am. Ceram. Soc.* 12, 455-6 (1929).—A general discussion.

C. H. KERR

**The use of a small cupola in testing cupola refractories.** JAMES T. MACKENZIE. *J. Am. Ceram. Soc.* 12, 443-6 (1929).

C. H. KERR

**Apparatus for determining the crushing strength of refractory materials at very high temperatures: study of fused magnesia.** G. CHAUDRON, M. GARVIN and A. VILLACHON. *Chimie & industrie Special No.*, 330 (Feb., 1929).—In order to see if large  $MgO$  crucibles would have the required mech. strength for use on a com. scale in a furnace such as described in *C. A.* 22, 4384, an app. was designed for accurately detg. the crushing strength of refractories above  $1600^\circ$ . Pure  $MgO$  behaves satisfactorily at  $2200^\circ$ , undergoing only a viscous deformation; addn. of 1.6%  $SiO_2$  considerably increases the fragility at high temp.;  $Al_2O_3$ ,  $Cr_2O_3$  and  $Fe_2O_3$ .  $CaO$  apparently do not affect the mech. properties of pure  $MgO$ , the  $Fe_2O_3$ .  $CaO$  even reducing the viscosity slightly.

A. PAPINEAU-COUTURE

**The effect of sodium silicate on casting slips.** K. SILK and N. D. WOOD. *Pottery Gaz.* 54, 272-3 (1929).—The authors discuss the comparative effects on earthenware slip of varying  $Na_2O:SiO_2$  ratios in Na silicate. The fluidity of the casting slip showed a marked similarity between the results obtained with Na silicate of different sp. gr. In every case most of the deflocculation obtainable had been achieved at a concn. corresponding to 0.02%  $Na_2O$  of the body. Increasing the proportion of  $SiO_2$  in the Na silicate slightly thickened the slip. The effect of an increasing  $Na_2O:SiO_2$  ratio on an earthenware body was found to be the reverse of the effect on a china body.

R. A. HEINDL

**Increasing dried-ware strength with lignin extract.** R. M. KING. *Brick and Clay Record* 73, 97-8 (1928).—Gum arabic, dextrin, coal tar, molasses, and other org. binders have been used to increase the dry-strength of ceramic wares. Lignin ext. has been used for many years to strengthen the cores of foundry molds. By adding 2% lignin to sagger bodies their strength was increased 91%. 0.5% lignin increased the dry-strength of a tile body 125%. The addn. of lignin to ceramic bodies is suggested as a substitute for some of the plastic ball clay.

H. G. SCHURECHT

**Modern practice crystallized in new tunnel kiln.** GEORGE S. HOUSMAN and GILBERT E. SKIL. *Chem. Met. Eng.* 36, 340-3 (1929).—A new Dressler tunnel kiln is described.

C. H. KERR

**A coke-fired gas producer for the ceramic industry.** H. C. BARRETT. *J. A. Ceram. Soc.* 12, 435-42 (1929).

C. H. KERR

**Present practice in whiteware periodic kiln design.** R. G. MILLS. *J. Am. Ceram. Soc.* 12, 481-90 (1929).

C. H. KERR

**The incrustation of ceramic ware.** THEODORE LENCHNER. *J. Am. Ceram. Soc.* 12, 498-501 (1929).—A history and general description are given of the application of gold and other precious metals over acid-etched designs on glass, china and enamel ware.

C. H. KERR

**Kiso-stone as a raw material for pottery.** JIROKICHI KUMAZAWA. *J. Japan. Ceram. Assoc.* 36, 552-4(1928).—Kiso-stone is a liparite contg.  $\text{SiO}_2$  72.28,  $\text{Al}_2\text{O}_3$  15.18,  $\text{Fe}_2\text{O}_3$  1.30,  $\text{CaO}$  0.37,  $\text{MgO}$  0.39,  $\text{MnO}$  0.06, alkalis 5.62%. Loss on ignition is 4.25%. If cut, it looks like a well-grained wood. Plates of the material are used raw or fired to about  $1100^\circ$ . Scrap produced in making plates is utilized by manufacturers of terra-cotta and tiles. Bodies composed of Kiso-stone 55-65, Kibushi clay of Seto 20-30 and feldspar of Yodo, Tokigun, 15%, with an ordinary raw glaze, fired at cone 6a, have given satisfactory results. They are cream-colored and suitable for the manuf. of terra-cotta, tiles, sanitary ware, etc. S. KONDO

**Linoleum block printed pottery.** SADIE LOSHINSKY. *J. Am. Ceram. Soc.* 12, 502-4(1929). C. H. KERR

**Copper ruby glaze.** II. TOSAKU YOSHIOKA AND SHO HIRAOKA. *J. Japan. Ceram. Assoc.* 36, 154-60(1928); cf. *C. A.* 23, 2261.—Frits of 0.25  $\text{Na}_2\text{O}$ , 0.15  $\text{K}_2\text{O}$ , 0.60  $\text{CaO}$ , 0.25  $\text{Al}_2\text{O}_3$ , 3.0  $\text{SiO}_2$ , 0.25  $\text{B}_2\text{O}_3$  + 1%  $\text{CuO}$  + 1 to 5%  $\text{Fe}_2\text{O}_3$ ,  $\text{PbO}$ ,  $\text{SnO}_2$  or  $\text{ZnO}$  were prepd. in a heavy-oil kiln and were reheated in an atm. of  $\text{N}_2$  or  $\text{CO}_2$  at  $600^\circ$ ,  $700^\circ$ ,  $800^\circ$  or  $900^\circ$  for 1 hr.  $\text{PbO}$  and  $\text{ZnO}$  seem rather to counteract the production of red. Both  $\text{Fe}_2\text{O}_3$  and  $\text{SnO}_2$  give deep ruby reds in  $\text{N}_2$  and  $\text{CO}_2$  atm.  $\text{SnO}_2$  gives more beautiful reds than  $\text{Fe}_2\text{O}_3$ . The suitable amt. of the oxides ranges from 2 to 4%. The best reheating temp. is  $700^\circ$ .  $\text{CO}_2$  produces reds at lower temp. but less clear than  $\text{N}_2$ . The same frits contg. 2-4%  $\text{SnO}_2$  prepd. in an atm. of  $\text{N}_2$  and reheated in the same gas at  $700^\circ$  or  $800^\circ$  had red colors, though they were lighter than those described above. Then the same frits contg. 1-5%  $\text{SnO}_2$  were prepd. from batches, to which the theoretical amt. of cane sugar required for the reduction of  $\text{CuO}$  to  $\text{Cu}_2\text{O}$  had been added, in an atm. of  $\text{N}_2$ . The frits were greenish when cooled quickly, and deep red if cooled slowly. Beautiful deep red frits were obtained by reheating the frits contg. 2-4%  $\text{SnO}_2$  at  $700^\circ$ . Too long heating gives the frits brownish tints and makes them opaque; the time is influenced by the content of  $\text{SnO}_2$ . S. KONDO

**Salt glazing.** FELIX SINGER. *Chem. Fabrik* 1929, 309. J. H. MOORE

**Cast iron capable of being enameled.** A. MÜLLER. *Giesserei-Ztg.* 26, 247-50 (1929); cf. *C. A.* 23, 3065.—The ratio of shrinkage between cast iron and enamel increases with increasing C and Mn contents, and decreases with increasing Si and P contents. Graphite-rich irons show a smaller shrinkage than graphite-poor irons. Shrinkage in hot-cast pieces is smaller than in cold-cast pieces. Cast iron of the following compn. may be enameled: C 3.6-3.7, Si 2.3-2.6, Mn 0.6-0.9, P 0.6-0.9 and S 0.08-0.1%. J. W. W. SULLIVAN

**Cause and control of color variation in cast-iron and sheet-iron enamels.** W. F. WENNING. *J. Am. Ceram. Soc.* 12, 491-3(1929).

**A deformation study of cobalt oxide-iron oxide-silica mixtures.** JOHN F. SHEPHERD. *J. Am. Ceram. Soc.* 12, 494-7(1929).—The deformation eutectic temp of  $\text{Fe}_2\text{O}_3$ - $\text{Co}_3\text{O}_4$  is  $1410^\circ$  and the compn. is 46%  $\text{Co}_3\text{O}_4$  and 54%  $\text{Fe}_2\text{O}_3$ . The eutectic 36%  $\text{Co}_3\text{O}_4$ , 42%  $\text{Fe}_2\text{O}_3$  and 22%  $\text{SiO}_2$  melts at  $1150^\circ$ . The color of the fused cones is uniformly steel-gray. Either of the two eutectics is similar in phys. properties to fused  $\text{Co}_3\text{O}_4$  and might be substituted for it in ground-coat enamels with a lowering in firing temp. and in cost. C. H. KERR

**A laboratory slagging test for boiler-furnace refractories (HURSH) 21.** A study of crystalline compounds formed in slags on boiler-furnace refractories (KLINEFELTER, REXFORD) 21. Apparatus for drying clay, sand, chalk, etc. (Fr. pat. 656,913) 1. Cement [for repairing ceramic ware] (U. S. pat. 1,719,914) 18. Method of and means for cooling annealed products (Ger. pat. 478,390) 13.

**D'HUBERT: Les chaux, les ciments et les produits ceramiques.** New ed. Paris: J.-B. Ballière et fils. 96 pp. F. 5.

**Working glass and similar substances.** J. VIATOUR. Belg. 355,730, Dec. 31, 1928. The flame is obtained by means of a gaseous hydrocarbon of high calorific value (except  $\text{CH}_4$ ), preferably a mixt. of  $\text{C}_2\text{H}_2$  and  $\text{O}_2$ .

**Device for regulating the flow of molten glass from tank furnaces or forehearth.** SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST.-GOBAIN, CHAUNY, ET CIRÉY. Brit. 301,919, Dec. 8, 1927. Structural features.

**Feeding and circulating molten glass.** KARL E. PEILER (to Hartford-Empire Co.). U. S. 1,721,487, July 16. Mech. features.

- Apparatus for delivering mold charges of molten glass.** ALBERT F. TREMBLAY. U. S. 1,720,496, July 9. Structural features.
- Furnace, gravity-flow apparatus, etc., for sheet glass manufacture.** WILLIAM E. BOCK (to Erie Glass Co.). U. S. 1,720,029, July 9.
- Apparatus for sheet glass manufacture.** SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST.-GOBAIN, CHAUNY, ET CIREY. Brit. 302,283, Dec. 13, 1927.
- Drawing sheet glass.** ENOCH T. FERNGREN (to Libbey-Owens Sheet Glass Co.). U. S. 1,720,547, July 9. Three streams of glass are caused to flow downwardly; one of the outer streams is heated and the other is cooled and the three streams are merged and consolidated. An app. is described.
- Apparatus for drawing sheet glass.** CLIFFORD A. ROWLEY (to Libbey-Owens Sheet Glass Co.). U. S. 1,720,527, July 9.
- Apparatus for plate glass manufacture.** W. OWEN (to Pittsburgh Plate Glass Co.). U. S. 1,720,745, July 16.
- Fused silica sheets.** QUARTZ ET SILICE. Brit. 302,895, Dec. 23, 1927. Panes or sheets for windows are made of transparent fused silica by submitting a mass of opaque fused silica, which has been heated to about 2000°, to a high pressure (suitably 200–600 kg. per sq. cm.) which is maintained until solidification occurs.
- Apparatus for molding bottles or other glass articles.** SYDNEY HUNT. U. S. 1,720,552, July 9. Structural features.
- Apparatus for making bottles or other blown glassware.** ROBERT F. HALL. U. S. 1,720,598, July 9. Structural features.
- Apparatus for manufacture of lamp bulbs or other blown glassware.** NAAMLIOOZE VENNOOTSCHAP MAATSCHAPPIJ TOT EXPLOITATIE VAN UITVINDINGEN. Brit. 302,153, Dec. 10, 1927.
- Apparatus for coloring the inner surface of electric lamp bulbs.** J. T. FAGAN and R. G. PHELPS (to British Thomson-Houston Co., Ltd.). Brit. 301,841, Dec. 6, 1927. An app. is described suitable for applying powdered pigment to the etched inner surface as described in Brit. 300,179 (C. A. 23, 3553).
- Spray-coating the inner surface of lamp bulbs, etc.** A. M. HAGEMAN and A. F. LINDSTROM (to Westinghouse Lamp Co.). Brit. 302,170, Dec. 9, 1927. An app. is described having a nozzle which may be cleaned by use of a steam jet and may be used for applying coatings such as those contg. Na silicate, kaolin and pigment.
- Frosting the inside of lamp bulbs by etching.** ELEKTRISCHE GLÜHLAMPENFABRIK WATT A.-G. Brit. 302,582, Dec. 17, 1927. After a first etching with a compn. such as may be formed from  $\text{NH}_4\text{F}$ ,  $\text{HCl}$ ,  $\text{CaCl}_2$ , water,  $\text{HF}$  and  $\text{BaSO}_4$ , a further etching with a weaker soln. derived by hydrolysis or dissocn. from the first soln. is effected to round off the sharp edges formed during the first etching.
- Bulbs for incandescent electric lamps, etc.** M. PIPKIN (to British Thomson-Houston Co., Ltd.). Brit. 301,830, Dec. 6, 1927. Opal, white or other natural colored bulbs are frosted on the inside, preferably by etching. All or a portion of the outside may be coated (suitably as described in Brit. 196,843 (C. A. 17, 3766)).
- Apparatus for manufacture of glass stoppers or similar pressed glass articles.** W. B. MITCHELL. Brit. 302,193, Aug. 11, 1927. Structural features.
- Lehr for annealing glassware.** JOHN MAYO (to Thermal Engineering Corp.). U. S. 1,719,897, July 9. Structural features.
- Treating copper leading-in wires of lamps, discharge tubes or similar electrical devices.** CHARLES T. DEGROAT (to General Electric Co.). U. S. 1,719,877, July 9. While annealing a glass stem through which a Cu leading-in wire extends, the latter is surrounded by a shielding tube which may be formed of Cu and which is of slightly larger diam. than that of the wire; this tube is removed after the annealing operation.
- Tunnel kiln construction suitable for burning bricks, tile, etc.** W. L. HAWLEY, JR. U. S. 1,720,550, July 9.
- Chamber kiln for bricks, lime, etc.** FIRMA K. H. PAUL, LUDWIG. Ger. 478,182, Feb. 15, 1927.
- Refractory material.** DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Fr. 657,406, June 25, 1928. See Brit. 292,958 (C. A. 23, 1487).
- Refractory materials.** FELIX J. MALHERBE. Fr. 656,923, July 3, 1928. Refractory materials particularly furnace hearths are hardened by impregnation with  $\text{Na}_2\text{SiO}_3$  or  $\text{K}_2\text{SiO}_3$  or both, so that the silicates penetrate into the interior and dry there, while the exterior is freed from silicate. The silicates may be used in soln. in petroleum.

**Refractory material obtained as slag.** T. R. HAGLUND. Brit. 302,087, Feb. 18, 1928. In reducing oxides or ores in an elec. furnace for the production of iron or other metals or alloys such as those of Cr, the charge is so made up (as by adding magnesite and bauxite) that a highly refractory slag is obtained contg. less than 15% silicic acid and otherwise formed mainly of MgO and  $Al_2O_3$ . Oxides of Cr and Fe also may be present and up to one-fourth of the Mg may be replaced by Ca. The slags may be cast or may be used with colloidal binders.

**Manufacture of basic products for lining metallurgical furnaces.** P. RIES and F. BICHEROUX. Belg. 356,350, Jan. 31, 1929. Tar and a powdered mineral flux are added to a basic refractory which has been fritted and coarsely ground. The mixt. is heated to a temp. slightly below the combustion temp. of the tar, the mass is molded under pressure and finally baked at such a temp. as will give it the strength of ordinary refractories.

**Abrasive sheet material.** C. KLINGSPOR. Brit. 302,430, Oct. 5, 1927. Abrasive powder is secured to a backing such as paper by an adhesive comprising animal glue and a phenol- $CH_2O$  condensation product which is hardened and rendered waterproof by heating to a temp. not exceeding  $150^\circ$ . Various details of manuf. are given.

**Abrasive paste.** PAUL TIETZ. Ger. 478,260, Oct. 19, 1924. The abrading ingredient, *e. g.*, pumice or emery, is mixed with a concd. soln. of a hygroscopic salt. A soln. of Ca lactate is preferred, and with this soln. there may be incorporated, before addn. of the abrading substance, finely divided metal oxides, especially ZnO or lithophone.

**Ceramic material.** BORGESTAD FABRIKKER. Fr. 34,049, Sept. 14, 1927. Addn to 623,573. A ceramic material is made from particles of natural olivine rock agglomerated with Mg orthosilicate obtained artificially, *e. g.*, from talc and magnesite. The olivine rock may be replaced partially or wholly by particles of Mg orthosilicate. Cf. C. A. 23, 946.

**Ceramic products.** RUDOLF POLLAK and WILHELM WEBER. Austrian 113,330, Jan. 15, 1929. Ceramic products of improved properties are obtained from alkali-free Mg silicates such as serpentine, chlorite and steatite by mixing with the silicates an alkali-free alk. earth compd. ( $BaCO_3$ ) and  $Al_2O_3$  in a total amt. not exceeding 10%, the finely ground mixt. being molded and fired in the usual way. Graphitic objects can also be obtained by mixing 30% or so of graphite with the mixt. as above.

**Ceramic ware.** CERAMIC PATENT HOLDINGS, LTD., and J. W. MELLOR. Brit. 302,519, Jan. 31, 1928. In order to reduce the temp. required for firing unglazed ceramic ware, the material of which it is formed is admixed with 2-5% of a flux composed of an alkali silicate or a borate of an alk. earth metal or Mg (or a mixt. of such compds.).

**Ceramic glaze.** DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Fr. 656,829, June 29, 1928. See Brit. 293,317 (C. A. 23, 1732).

**Enamels and glazes.** DYNAMIDON-WERK ENGELHORN & CO. G. M. B. H. Ger. 477,800, Nov. 18, 1927. The resistance of enamels and glazes to chemicals is increased by addn. of sillimanite or corundum.

**Enamel with a cement base.** E. J. PEETERS. Belg. 355,628, Dec. 31, 1928. The enamel is composed of a single kind of cement (nature not specified), roasted clay ("gaize"), paraffin,  $CaCO_3$  and coloring oxides. Cf. C. A. 23, 2545.

**Enamel ware.** I. G. FARBENIND. A.-G. and EISENWERK KAISERSLAUTERN A.-G. Ger. 477,721, Dec. 20, 1927. Cast- and wrought-iron objects are subjected to a vacuum during or after the application of the enamel coating, and are then re-subjected to atm. pressure.

**Spark plug insulation.** SIEMENS & HALSKE A.-G. Brit. 302,893, Dec. 23, 1927. The insulation or that portion of it nearest the combustion chamber is made of fused  $Al_2O_3$  such as artificial sapphire or ruby and the exposed surface is polished to minimize deposits on it.

## 20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

**Thermal expansion of cement and its mixtures.** SHICHIRO UCHIDA. Sendai Higher Tech. School. *Bull. Sendai Higher Tech. School* 7, 425-78(1928); cf. C. A. 23, 2799.—Portland cement, alumina cement and mixed cement were studied alone and with addns. of volcanic ash, calcite, siliceous earth, diatomaceous earth and sand. Pure cement expands up to  $100^\circ$ , then contracts, so that above  $200^\circ$  the length be-

comes smaller than at the outset. At 300–400° the rate of contraction becomes a little less rapid; above 400°, the contraction is again considerable up to 700°. Many mixed cements have marked expansion above 400°. The expansion coeff. slightly increases with temp. and differs a little with the amt. of H<sub>2</sub>O and added substance. Alumina cements generally show small expansion coeff. K. SOMEYA

Tentative specifications, finish coat portland cement stucco. Report of Subcommittee 1 of Committee C-3. W. E. HART, W. D. M. ALLAN, et al. *Proc. Am. Concrete Inst.* 25, 561–5(1929). J. C. WITT

Volumetric changes in portland cement mortars and concretes. RAYMOND E. DAVIS AND G. E. TROXELL. *Proc. Am. Concrete Inst.* 25, 210–60(1929); cf. C. A. 22, 4753.—The work has extended over a period of nearly 4 years, and at present more than 400 concrete and mortar specimens are under observation. The test program includes richness of mix, gradation of aggregate, quantity of mixing water, character of aggregate, moisture conditions including variations in humidity, conditions of curing, the effect of alternating periods of water soaking and drying, the effect of admixtures and the effect of the surrounding medium. J. C. WITT

The mechanism of corrosion of portland cement concrete with special reference to the role of crystal pressure. F. O. ANDEREGG. *Proc. Am. Concrete Inst.* 25, 332–43 (1929).—A. summarizes the work as follows: All building materials are undergoing a slow disintegration in which the presence of water is the most important factor. Portland cement concrete cannot escape the laws of nature; all that can be hoped for is to make its resistance similar to that of the most resistant natural rocks. Concrete must withstand, when rain or ground water comes in contact with it, a leaching out of lime, a reaction with the sulfate always present in natural waters (even in rain water), a crystal pressure resulting from efflorescent action which is aided both by evapn. from a surface and by drops in temp. Therefore the importance of preventing water from entering and passing through the concrete should be emphasized. An accelerated method of detg. the resistance of concrete to crystal pressure has been developed in which the chem. attack of the sulfate is minimized, by taking advantage of crystn. behavior with slowly falling temp. Expts. have been made with cement flour contg. 4.5–6.5% SO<sub>3</sub>. Retrogressions in strength at early ages were noted, but readjustments occurred so that after storage for 28 days and longer remarkably high strengths were obtained. The crystals present were practically all of lime. The results fail to develop any evidence that the presence of gypsum in amts. that will react with the aluminate before the concrete had begun to set is dangerous. This has bearing on the SO<sub>3</sub> specification. A method for the mech. molding of specimens has been developed which is especially valuable for making smaller specimens, but which can also be used very advantageously for larger ones. The conclusions of Klein and Phillips about the dangers resulting from the pressures developed by lime crystals have been confirmed, but these effects are usually only temporary because of the property of concrete flowing to a slight extent under pressure. J. C. WITT

Influence of added salts upon the time of setting of portland cement. MANJIRO NAKAHARA. *Bull. Tokyo Ind. Research Inst.* 23, 1–24(1928).—Portland cement clinker was finely powdered and the influence of the addn. of various sol. and insol. substances on the setting time was tested. The influence of added salts is not necessarily due to the negative or to the positive radical alone, but both the positive and the negative groups have some effect. Hence the time of setting may be lengthened to a suitable limit not only by gypsum, which is now commonly used, but also by some other substances. In studying the effect of added reagents upon cement the reagent must be added to the clinker itself, or the influence upon the time of setting is not clearly evident, because of the disturbing effect of CaSO<sub>4</sub>. K. SOMEYA

Exposure to calcium dusts generated in the manufacture of portland cements. L. R. THOMPSON AND DEAN K. BRUNDAGE. *J. Ind. Hyg.* 11, 182–93(1929).—The phys. analysis of numerous air samples taken at various places in a portland cement plant showed that the no. of particles under 10 $\mu$  ranged from 337,000 to 105,630,000 per cu. ft. and the no. of particles over 10 $\mu$  ranged from 8500 to 1,069,000. The total solids amounted to 0.025–5.675 mg. per cu. ft. The chem. analysis of the dust gave the following results: 15.00–21.30% SiO<sub>2</sub>; 4.20–9.10% Fe<sub>2</sub>O<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub>; 36.11–60.88% Ca; 2.06–2.97% MgO; 1.75–4.08% SO<sub>3</sub>; loss on ignition 4.75–40.40%. The uncombined silica was about 6.5% before the cement was burned in the kiln; afterwards the free silica in the dust of the resp. rooms was reduced to 1%. The exposure to the Ca dusts seemed to predispose the workers to certain diseases as acute bronchitis, diseases of the nasal fossae, pharynx and tonsils, skin, eyes and ears, digestive system, and influenza and grip. G. SCHWOCH

**The rate of hydration of cement clinker.** F. O. ANDEREGG AND D. S. HUBBELL. *Proc. Am. Soc. Testing Materials*, No. 60 (preprint) 11 pp. (1929).—The cement clinker was sepd. into suitable fractions by means of a Pearson elutriator (Bur. of Stand. *Tech. Paper* No. 47) and expts. were made. Conclusions: (1) The rate of hydration is rapid at first and then falls off. (2) The presence of  $\text{CaSO}_4$  appears to decrease the rate of hydration between the 1st and 28th day of storage. (3) At 24 hrs. the depth reached by the hydration of a typical portland cement clinker is about 0.5 micron, at 7 days about 1.5, at 28 days above 3.5 and at 90 days about 5 microns, in the presence of  $\text{CaSO}_4$  and for particles of 15 to 30 microns dimension. (4)  $\text{CaCl}_2$  does not seem to affect the rate of hydration. (5) Hydration over short periods of time seems to be retarded by low temps. and hastened by high temps.; but after storage of 7 to 28 days, the amt. of hydration is apparently very nearly the same over the temp. range 32 to 100°F. (6) The high-early-strength portland cement did not appear to have a greater rate of hydration at 24 hrs. than the others, although at 7 and 28 days an appreciably greater rate was observed. (7) A preliminary est. gives the increase in vol. of portland cement during hydration as about 50%. (8) The hypothesis of Giertz-Hedström and Werner (*C. A.* 23, 2264) that the compressive strength of cement and concrete is proportional to the square of the part of the cement hydrated is confirmed. However, this confirmation is probably accidental; for instance, on increasing the water-cement ratio the hydration would not be decreased, while the early strengths are affected more than later ones.

A. J. MONACK

**Comparison of methods of determining moisture in sands.** WM. R. JOHNSON. *Proc. Am. Concrete Inst.* 25, 261-79 (1929).—The following methods were compared by testing in turn 3 samples of sand, each with 4 percentages of moisture: elec. resistance moisture meter, drying to const. weight in oven, drying to const. weight with denatured alc., displacement method using cylindrical container, displacement method using A. S. T. M. flask, sp. gr. method using a salt soln. hydrometer. The best results were obtained with the methods requiring the simplest manipulation—the drying methods ranking first in accuracy, the displacement methods next and the hydrometer last.

J. C. WITT

**Science and art of concrete manufacture.** L. W. SKOV, *et al.* *Am. Ry. Eng. Assoc. Proc.* 30, 804-12 (1929).—Moisture in aggregate and the method for detn. is stressed.

R. C. BARDWELL

**Durability of concrete—progress report of Committee E-6.** A. E. LINDAU. *Proc. Am. Concrete Inst.* 25, 27-82 (1929).

J. C. WITT

**Concrete products plant operation.** Report of Committee P-6. E. GRANT LANTZ, *et al.* *Proc. Am. Concrete Inst.* 25, 573-601 (1929).

J. C. WITT

**Three and one-half years' experience of the Detroit Edison Company in concrete control.** A. S. DOUGLASS AND J. S. NELLES. *Proc. Am. Concrete Inst.* 25, 100-51 (1929).

J. C. WITT

**A scientific trial method for designing concrete mixtures.** R. E. ROBB. *Proc. Am. Concrete Inst.* 25, 280-91 (1929).—R. describes the use of some special app. and a no. of charts for arriving at the desired results.

J. C. WITT

**Water tables and curves for use in designing and estimating concrete mixtures.** HERBERT J. GILKEY. *Proc. Am. Concrete Inst.* 25, 292-313 (1929).

J. C. WITT

**The absolute basis of proportioning concrete and its economy.** JOSEPH A. KITTS. *Proc. Am. Concrete Inst.* 25, 741-50 (1929).—The factors involved are the abs. vols and gradation of sizes of particles in a mix, the water required for workability and the cement required for the strength or other properties of the concrete. Aggregates from the same source vary widely from day to day in a no. of characteristics and sufficient information must be obtained before proportioning can be carried out in a satisfactory manner.

J. C. WITT

**Researches on concrete materials and on plain and reinforced concrete.** Report of Committee E-3. H. F. GONNERMAN, *et al.* *Proc. Am. Concrete Inst.* 25, 432-96 (1929); cf. *C. A.* 22, 3274.—The report is outlined as follows: researches on cement (constitution, workability, testing); researches on aggregates (types of aggregates, durability, grading, abrasion, detn. of moisture); researches on plain concrete (absorption, admixtures, autogenous healing, bond, chem. analysis, concrete products, crazing, curing, dams, durability, extensibility, fatigue, field control, flow under load, freezing and thawing, jiggling, modulus of elasticity, Poisson's ratio, pavements, permeability, placing, proportioning, protective treatments, compressive strength, flexural strength, temp. effects, tests and test methods, time of mixing, vol. changes, water-proofing, wear); researches on reinforced concrete (arches, beams, bond, bridges, reinforcing steel); suggested researches on concrete and related subjects (cement,

aggregate, concrete, reinforced concrete); references to papers and reports on researches published during 1928. J. C. WITT

**Characteristics of concrete for fire resistance.** Report of Committee E-4. N. D. MITCHELL, et al. *Proc. Am. Concrete Inst.* 25, 812-17(1929).—Most concretes are resistant to fires. In general the character of the aggregates is more important than that of the cement. The relative values of the common types of aggregates are discussed, and a bibliography on the fire resistance of concrete is given. J. C. WITT

**Specifications for concrete aggregates.** Report of Committee E-5. R. W. CRUM, et al. *Proc. Am. Concrete Inst.* 25, 656-68(1929). J. C. WITT

**Effect of temperature on the curing of concrete.** R. A. FOLEY. *Proc. Am. Concrete Inst.* 25, 566-72(1929).—High temps. during the initial curing period assist in producing high early strengths. The rate of increase of strength decreases with age of the product. Economic limits for the initial curing period are 48 hrs. during the summer months and 60 hrs. during the winter months at max. temps. of 90° to 110°F. Plain concrete pipe and similar thin-wall concrete products are more sensitive to temp. changes during the curing period than are mass products such as concrete block and brick. J. C. WITT

**High early strength concrete.** EDWARD E. BAUER. *Proc. Am. Concrete Inst.* 25, 314-31(1929).—The rate at which concrete gains strength depends on the kind of cement, water-cement ratio, temp., admixts., curing, and time of mixing. The effect of each of these is studied, and the results of a series of tests are presented. J. C. WITT

**Testing concrete for absorption.** FRED WEIGEL. *Proc. Am. Concrete Inst.* 25, 514-21(1929).—Permeability is the controlling factor with respect to the resistance of a material to the effects of fire, freezing and long periods of exposure to water and general weathering conditions. The samples, procedure, equipment and results are discussed. J. C. WITT

**The limitations of the absorption test for concrete products.** RAYMOND WILSON. *Proc. Am. Concrete Inst.* 25, 522-49(1929).—The absorption test as now made is of little value as a criterion of the quality of concrete products, because neither of the assumptions on which it is based is applicable to concrete. A form of specification based on the rate of absorption is suggested. J. C. WITT

**Concrete exposed to alkali ground waters.** J. C. MACKENZIE. *Proc. Am. Concrete Inst.* 25, 763-7(1929).—According to M. the significant findings of the past few years are (1) the actions of  $\text{Na}_2\text{SO}_4$  and  $\text{MgSO}_4$ , which formerly were supposed to be similar, differ materially and affect different cements in different ways; (2) concretes and mortars made from portland cements from different mills and from different raw materials may differ widely in their stability in alkali waters; (3) strength tests are not indicative of the relative sulfate resistances of different cements; (4) some high-alumina cements are very resistant to attack by  $\text{MgSO}_4$  and are more resistant to  $\text{Na}_2\text{SO}_4$  than most portland cements, but, on the other hand, they are quite easily attacked by  $\text{Na}_2\text{CO}_3$ , which is present in many localities in the West in the form of so-called "black-alkali"; (5) if even a lean concrete made from a cement of low natural resistance to alkali be steam-treated at a temp. not lower than 212°F. for a sufficient length of time, it can be made absolutely immune to attack by  $\text{Na}_2\text{SO}_4$  and very resistant to attack by  $\text{MgSO}_4$  and it is concluded that if a rich, strong, impermeable concrete made from a cement of high resistance to alkali be so steam-treated it will be not only immune to attack from  $\text{Na}_2\text{SO}_4$  but will be also practically immune in  $\text{MgSO}_4$  waters. If the temp. be less than 212° such resistance is not developed and under certain conditions the resulting product may be made even less resistant. J. C. WITT

**Concrete for resisting sea water.** HARRY E. SQUIRE. *Proc. Am. Concrete Inst.* 25, 751-62(1929).—It may be stated with assurance that the methods of ordinary good practice will produce a concrete (plain) so durable in sea water that for the engineer's purposes it can be considered permanent. Durability is obtained not through the chem. inertness of the cement itself but through the mech. resistance of the concrete to the circulation of sea water in the interior mass. With reinforced concrete there are limitations of concrete in protecting steel exposed to the electrolytes of the sea, and there is the necessity of maintaining these structures by periodic painting and occasional repairs. Progress in constructing more resistant reinforced structures must come in a large part from the metallurgist in developing non-corrosive coatings for the steel. J. C. WITT

**Tests of retempered concrete.** H. F. GONNERMAN AND P. M. WOODWORTH. *Proc. Am. Concrete Inst.* 25, 344-87(1929).—The investigation included a study of the effect of the following factors or treatments on the strength and workability of concrete of a

wide range of water-cement ratios, after standing for periods up to 6 hrs. in air-tight cans or in pans exposed to the air of the lab. before use: remixing without the addn. of water; remixing with addn. of water to restore the concrete to its original condition of workability as measured by the flow test; type of aggregate; addn. of aggregates to cement pastes which stood for periods up to 6 hrs.; dry and soaked aggregates; admixts. of hydrated lime or celite; premixing cement and water for periods up to 30 min. before adding aggregate and mixing for addnl. periods of  $\frac{1}{2}$  to 10 min. There is only a small loss in compressive strength, due to standing for periods up to 6 hrs. (protected from evapn.) of concrete remixed without the addn. of water. When remixed with the addn. of water to restore the original flow the strength decreases with increase in the water-cement ratio. When unprotected from evapn. there is an increase in strength. A bibliography is given.

**Specifications for cast stone. Report of Committee P-3.** L. A. FALCO, *et al* *Proc. Am. Concrete Inst.* **25**, 550-60(1929). J. C. WITT

**The physical properties of commercial cast stone.** JOHN TUCKER, JR., and G. W. WALKER. *Proc. Am. Concrete Inst.* **25**, 501-13(1929).—This paper presents some of the data which have been accumulated at the Bureau of Standards in connection with an investigation for the purpose of writing specifications on this material. Compressive strength, modulus of rupture and absorption tests have been made. The results presented in tables and graphs indicate a very wide range in the properties of cast stone.

**Accelerators and retardors for gypsum.** P. P. BUDNIKOV. *Zhur. Prikladnoi Khim.* **1**, 323-7(1928).—Addn. of acids, bases and normal and double salts to gypsum affects the character of the time-temp. curves during the process of setting. This can be explained by the increase or decrease of the soly. of gypsum and by the change in the rate of coagulation of the gel. It can be also due to formation of double compds and to the reactions which may occur between gypsum and the added substances.

**Open-trough impregnation of wood poles with the aid of the perforating process.** ROBERT NOWOTNY. *Z. angew. Chem.* **42**, 717-21(1929).—Expts. are reported upon the process of perforating wood to improve impregnation (cf. C. A. **19**, 880). Various arrangements and depths of holes were made, and treatments with NaF and HgCl<sub>2</sub> solns. for different times followed. The results showed better impregnation than with control specimens that were not perforated.

**Experimental production of roofing felts (SHAW, *et al.*) 23.** The study of hydration changes by a volume-change method (NEVILLE, JONES) **2**. A new acid-resisting cement for sulfite digesters (KREUGERS) **23**. Study of protective coatings for interior of steel tanks and underground pipe lines (DAVIDSON, *et al.*) **26**. Kiln for the treatment of lime, dolomite, natural cement, etc. (Belg. pat. 356,177) **1**.

**Einflüsse auf Beton. Ein Auskunftsbuch für die Praxis. Part I.** Edited by A. KLEINLOGEL. Berlin: Wilhelm Ernst und Sohn. M. 6.

**Cement.** WILHELM O. ZIMMERMANN. Ger. 477,609, Apr. 26, 1928. Addn. to 448,030. A cement is made by mixing wet sand with lime, and wet cement with sand and then mixing the whole together.

**Cement.** ALESSANDRO MAZZA. Fr. 656,892, July 2, 1928. Lime which has been used for defecating sugar solns. is mixed with clay and burnt to produce hydraulic lime or cement.

**Cements, paints, etc.** RODWELL'S COMPOUNDS, LTD. Fr. 657,512, July 16, 1928. A vehicle for paints and cements consists of an alkali silicate and NaNO<sub>2</sub>. An example contains com. Na<sub>2</sub>SiO<sub>3</sub> (140° Tw.) 60, water 35, satd. aq. soln. of NaNO<sub>2</sub> 5 vol. The compn. may be used for coating cement, etc., or for binding purposes with fireclays.

**Rotary kiln for burning wet cement materials, etc.** JOHAN S. FASTING (to F. L. Smidth & Co.). U. S. 1,720,786, July 16. Structural features are described, among which is a rapidly rotating distributing device in a slurry chamber connected with the kiln which discharges slurry into the chamber in finely divided condition by centrifugal action.

**Production of sulfuric acid and artificial portland cement from substances containing calcium sulfate.** H. MEURIS. Belg. 354,788, Nov. 30, 1928. Complete combustion of the reducing C is effected before it enters the clinkering zone, by reduction of CO<sub>2</sub> to CO, with addn. of a certain amt. of heat. The SO<sub>2</sub> is converted into H<sub>2</sub>SO<sub>4</sub>.

**Expansion joints for use with concrete, etc.** GEORGE W. MILLS, JR. (to Philip Carey Mfg. Co.). U. S. 1,720,229, July 9. A body of asphaltic compn. or similar bituminous material carries a superficial film of non-adhesive water-sol. material such as soap which serves to prevent adhesion during handling and storage before use.

**Pavement.** GEORGE M. SOUTER. U. S. 1,720,101, July 9. A pavement is formed comprising an asphalt-coated rock base, a thin layer of a mixt. of sand, dust and asphalt upon the base to waterproof it, and a surface of rock coated with asphaltic material pressed into the layer so that a substantial portion of the rock surface with interstitial spaces remains exposed to form a non-skid surface.

**Bituminous road-making composition.** W. H. SCHMITZ. Brit. 301,891, Dec. 8, 1927. Stone aggregate is first coated with mineral, vegetable or animal oil and then mixed with bitumen emulsion. Cf. C. A. 23, 3556.

**Bituminous composition for road surfaces.** G. COBB. Brit. 302,808, Dec. 28, 1927. A graded aggregate (such as crushed rock of various specified dimensions) is used with 3.5–5.0% of bitumen, tar or like material.

**Plastic masses.** FIRMA PAUL LECHLER. Ger. 477,760, July 9, 1925. Material for tarring roads is mixed with water. In an example pitch, coal-tar oil, bitumen emulsion and water are mixed to form a coating for roads.

**Infusible asphalt masses of high elasticity.** RICHARD LICHTENSTERN. U. S. 1,720,487, July 9. A batch of asphalt contg. not more than 10% of a condensing agent such as  $\text{FeCl}_3$ ,  $\text{AlCl}_3$  and  $\text{ZnCl}_2$  is heated to a temp. not over  $300^\circ$  (suitably about  $270$ – $80^\circ$ ) and then admixed with Chinese wood oil (not exceeding the quantity of asphalt used) and heating is continued until coagulation is effected. The product may be used on roads, floors or for treating pasteboard, etc.

**Slaking lime.** W. H. BARTON (to Blue Diamond Co.). U. S. 1,720,026, July 9. Quicklime is mixed with water at about the b. p. in proportions to form a lime putty.

**Coloring magnesium oxychloride stucco.** MAX Y. SEATON (to National Kellastone Co.). U. S. 1,720,972, July 16. A Mg oxysulfate coating is applied to the stucco in order to correct non-uniformity of coloring at the surface.

**Draining damp walls.** ERNST MURMANN. Ger. 478,466, June 21, 1925. Dampness in walls is ascribed to the presence of nitrates of Ca and Mg and, in order to drain the walls, these salts are decompd. by means of  $\text{K}_2\text{SO}_4$ . Thus,  $\text{K}_2\text{SO}_4$  may be added to the mortar, or a layer of mortar contg.  $\text{K}_2\text{SO}_4$  may be interposed between the stone and the plaster. Alternatively, a loose mortar comprising  $\text{K}_2\text{SO}_4$ , sand and sawdust or kieselguhr may be inserted into holes in the wall and the wall then plastered as usual.

**Building material.** JAMES H. YOUNG (to H. H. Robertson Co.). U. S. 1,720,708, July 16. Shingles or the like comprise a portion of cement and asbestos or other fibrous material, a covering of a relatively thin layer comprising irregularly shaped particles of metal such as Zn or Pb fused together without destroying their individual contour, and an outer thin layer of Cu bonded to the first-mentioned metal layer.

**Wall board.** CALEB PAYNE (to Gypsum Engineering & Mfg. Co.). U. S. 1,720,-855-6, July 16. Mech. and structural features and an app. are described.

**Cellular plaster.** HARRY E. BROOKBY. U. S. 1,720,032, July 9. A cellular product is formed by gaging with water a mixt. contg. partially calcined gypsum as the main ingredient together with  $\text{NaHCO}_3$ , Mg fluosilicate, soap bark and  $\text{Ca}(\text{OH})_2$ .

**Tiles of asbestos compositions or similar articles coated with an adherent layer of resinous condensation product.** LAWRENCE E. BARRINGER (to General Elec. Co.). U. S. 1,721,367, July 16. Products are described suitable for use in making refrigerators, for building construction, etc.

**Floor covering composition.** JOHN C. WICHMANN (to Cactus Rubber Co. of America). U. S. 1,720,533, July 9. Ground cork 25, pumice 15, magnesite 10, diatomaceous earth 10, linseed oil 5 and a rubber compd. derived from cactus 35 parts.

**Waterproof floor-covering material.** CLIFFORD S. COOLEY. U. S. 1,720,780, July 16. A fibrous material of light color such as a felt is impregnated with a compn. of neutral color which contains rosin oil and may also contain "lead and manganese dryer."

**Flexible floor and wall-covering material.** P. C. VAN DER WILLIGEN and N. V. NEDERLANDSCHE LINOLEUMFABRIEK. Brit. 301,901, Dec. 8, 1927. Coating materials for making linoleum or similar products, in the form of colloidal solns. or emulsions are mixed and the colloids are afterward coagulated (suitably by adding an electrolyte or passage of an elec. current). Various examples, details and modifications are described.

**Graining wood.** E. E. SPARGO. Brit. 302,027, Nov. 10, 1927. The effects may be made more distinct by a preliminary treatment of the wood with a soln. of  $\text{Na}_2\text{CO}_3$

or with an aniline dye. An app. is described for forming grooves or indentations in the surface of the wood which may then be planed down to the bottom of the indentations which show markings from the compression.

**Protecting wood, iron and other surfaces from the atmosphere.** JAMES R. HATMAKER. U. S. 1,720,177, July 9. The surface is snugly fitted with a covering of fibrous material knitted in tubular form and this material is then impregnated with a protective compn. such as described in Brit. 272,142 (C. A. 22, 1862).

**Preserving and waterproofing wood.** I. G. FARBENIND. A.-G. Brit. 302,698, Dec. 20, 1927. Wood is impregnated with cellulose trilaurate, starch laurate or other suitable higher aliphatic esters, ether-esters or mixed esters of carbohydrates.

**Wood-preserving composition and fungicide.** ALBERT L. KLEES and ROLAND P. SOULE (to Combustion Utilities Corp.). U. S. 1,720,905, July 16. A refined dehydrated product is prepd. comprising primary acid tars of which at least 50% distil above 220°.

## 21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

**Liquid fuels.** E. GENSKE. *Chem.-tech. Rundschau* 44, 734, 763(1929).—The storage, handling and evaluation of petroleum fractions, benzene and alc. are discussed. Benzene produces more soot on combustion than does benzine; the difference can be lessened by admixt. with benzine or alc.

**The problem of engine fuel requirements.** J. M. SHOEMAKER. *Aviation* 26, 2274-7(1929).—Discussion of characteristics of aircraft fuels and important part they play in efficient and economic operation. The development in aviation gasoline used in Naval aircraft is outlined.

**Fuel briquets in 1928.** O. E. KIESSLING AND J. M. CORSE. Bur. Mines, *Mineral Resources of the U. S. 1928*, Pt. II, 1-11 (preprint No. 1 published June 7, 1929).

**Natural and manufactured smokeless fuel.** J. ROBERTS. *Power Eng.* 24, 279-81 (1929).—The smoke and fuel problem are considered from the standpoint of coal distn. under headings: initial decompn., formation temps., incombustible volatile matter, manufd. smokeless fuel and low-S coals. Curves showing temps. of initial decompn. of coal are given.

**Fineness of pulverized fuel as affected by mill types.** L. T. WORK. *Fuels and Steam Power* (A. S. M. E. Trans.) 50, No. 23, 87-95(1928).—Various principles of mill action make fuels of different degrees of fineness. Air-classifying schemes are outlined and W.'s turbidimetric method for measuring superfine is described.

**Pulverized-fuel firing.** J. O. TWINBERROW. *Power Eng.* 24, 285-6, 290(1929).—Recent developments are reviewed.

**Alcohol in industry.** M. C. WHITAKER. *Engrs. and Eng.* 46, No. 6, 147-8 (1929).—There are no technical difficulties remaining, either in making of alc. suitable for fuel blends or in use of fuels made therefrom. The problem is now solely one of suitable economic conditions, and one of public will.

**Atomization in carburetors.** J. SAUTER. *Natl. Advisory Comm. for Aeronautics—Tech. Mem. No. 518*, 10 pp.(1929).

**Presidential address [fuels].** M. BRAND. *Trans. Inst. Mining Eng.* (London) 77, 139-55(1929).—B. discusses fuel research; low-temp. carbonization; oils, tars and cracking to produce automotive fuels; powd. fuel; boiler firing; coal prepn., sampling, analysis, sizing and grading; hydrogenation of coal; safety; standardization; mechanization; hydroelec. power developments.

**Low-temperature carbonization. Modern practice on the commercial scale. II. The "Maclaurin" process.** DAVID BROWNIE. *Chemistry & Industry* 48, 619-22 (1929); cf. C. A. 23, 3790.—A description of the Maclaurin process and equipment. Cf. Lander, C. A. 23, 1244.

**The Bamag-Hellar low-temperature carbonization system.** W. KARSTEN. *Teer u. Bitumen* 27, 241-3(1929).—The app. and its operation are described and its advantages discussed. The unique feature is the passage of the coal by gravity through an inclined rotating multi-tubular drum retort, constructed of refractory material, previously heated by the upward passage of burning distn. gases. There is no other source of heat. Continuous operation is secured by operating 2 retorts in conjunction so that the distn. from each alternately furnishes fuel for the other. The heat-storing

and distn. periods are each  $\frac{1}{2}$  hr. The counter-flow principle, short heating time, manner of heat distribution and transfer, etc., result in high general efficiency and nearly ideal conditions for the production of a high yield of primary tar and thoroughly and uniformly exhausted semi-coke.

F. S. GRANGER

**Low-temperature coal processing for power production.** E. H. SMYTHE. *Power Eng.* 24, 277-8(1929).—Possibilities of coördinating coal processing and power production are considered, and a plant is described.

E. I. S.

**The hydrogenation process of the I. G. Farbenindustrie A.-G.** ANON. *Mining J.* (London) 165, 536(1929).—Synthetic  $\text{NH}_3$  is produced at Oppau and Leuna. The yearly production of N amounts to 130,000 tons at Oppau and 570,000 tons at Leuna, equiv. to  $3\frac{1}{2}$  million tons of fertilizer, about 770 million cu. ft. of air being used. At Oppau 800 tons of coke is used daily for water-gas production and 500 tons of brown coal for power gas. At Leuna brown coal is used for both purposes. Brown coal is also carbonized at low temps. to give tar for hydrogenation. The catalysts used in the hydrogenation process det. whether gasoline, kerosene, gas oil, fuel oil or lubricating oil will be produced.

ALDEN H. EMERY

**The hydrogenation of coal.** A. W. NASH. *Fuel Econ. Rev.* 8, 10-12(1929).—The Bergius process yields 90-130 gal. of tar per ton of coal and involves very much greater capital outlay, operating and maintenance costs than petroleum oil cracking processes. The chief value of fractions from the hydrogenation of coal by the Bergius process would be either as a motor spirit or a fuel oil. The nature of the product depends very largely upon the nature of coal used. By the use of catalysts greater flexibility is claimed and a decrease in reaction time without altering the optimum temp. and pressure. Catalysts now include oxides of Zn, Ni, Co and Cu. A mixt. of CO and H has been shown to be capable of yielding liquid fuels.

H. C. PARISH

**Study of some factors in removal of ash as molten slag from powdered-coal furnaces.** R. A. SHERMAN, P. NICHOLLS AND E. TAYLOR. *Trans. Am. Soc. Mech. Eng.* Advance paper, May 13-6, 1929, 12 pp.

E. I. S.

**A study of crystalline compounds formed in slags on boiler-furnace refractories.** T. A. KLINEFELTER AND E. P. REXFORD. *Trans. Am. Soc. Mech. Eng.* Advance paper, May 13-6, 1929, 2 pp.—Progress report of work done to date, of methods used, and difficulties encountered in lab. study of the equil. relation of oxides composing slags on boiler-furnace refractories at high temps. No data or conclusions are presented.

E. I. S.

**A laboratory slagging test for boiler-furnace refractories.** R. K. HURSH. *Trans. Am. Soc. Mech. Eng.* Advance paper, May 13-6, 1929, 6 pp.—Particulars of simulative service test of refractories with coal-ash slag made in a lab. furnace in which test brick form the lining of a cylindrical chamber rotated about a vertical axis. Tests have been made with slags representing coals used at five power stations where field tests were conducted.

E. I. S.

**Varieties of carbon and their reactivities.** R. V. WHEELER (experimental part by W. L. Wood). *Chaleur ind.* 9, No. 102, 160-1(1928).—Expts. indicate that it is erroneous to conclude that on cracking,  $\text{CH}_4$  gives only brilliant C while  $\text{C}_2\text{H}_4$  gives only the dull variety. Either, and even a third form, may be obtained depending upon the nature of the cracking surface, temp. and speed of gas.  $\text{C}_2\text{H}_4$  cracked at  $700^\circ$  to brilliant C;  $\text{CH}_4$  under the same conditions gave no C. The velocities of reduction of  $\text{CO}_2$  at  $1000^\circ$  with brilliant or with dull C from  $\text{CH}_4$  or  $\text{C}_2\text{H}_4$ , natural graphite, artificial graphite or fir-wood charcoal are 1-1.2, 19.1, 29.6 and 530.7, resp. The term "graphitic C" is not appropriate for coke with a metallic luster and luster of coke is no criterion of its reactivity.

S. L. B. ETHERTON

**Iron and coal.** TAIZO KUROTA. *J. Fuel Soc. Japan* 8, 607-20(1929).—The relation between the coal and iron industry with reference to the fuel problem is discussed.

F. I. NAKAMURA

**A microscopical study of some coals from Szechuan, S. W. China.** C. Y. HSIEH. *Bull. Geol. Soc. of China* 8, No. 1, 95-78(1929).—A description of the microscopic structure and constituents of 19 samples of coal, 6 of the Carboniferous age and the rest of the Jurassic.

E. I. S.

**Burning characteristics of different coals.** H. KREISINGER AND B. J. CROSS. *Fuels and Steam Power (A. S. M. E. Trans.)* 50, No. 23, 11-24(1928).—American coals have particular burning characteristics which differ according to the geological age of the coal and its chem. compn., phys. structure, moisture content and size. The geological age is shown by C, H and O contents. Characteristics of flame are affected by the compn. of the gases rising from the fuel bed and manner in which O is supplied

for their combustion. A comparison is made of processes of combustion in the fuel bed and in powd.-coal furnaces.

**Constitution and classification of coal.** A. C. FIELDNER. *Fuels and Steam Power* (A. S. M. E. Trans.) 50, No. 33, 1-9(1928); *Fuel Science Practice* 8, 36-45(1929).—Summary of considerations which are being kept in mind in classification of coal by the Am. Soc. Eng. Standards Committee.

**Properties and structural constituents of Ruhr coals.** W. RITTMEISTER. *Glückauf* 64, 589-94, 624-37(1928).—Coal from Wilhemine Victoria (gas coal) had 20-30% durain, 6-8% fusain, 30-40% vitrain and the rest was clarain. The Mansfeld mine coal has 85-90% vitrain, 2-3% fusain and the rest was durain. Lean coal from Demelsberg had 15% durain, 6-8% fusain, 30-40% vitrain and the rest was durain. R. met with samples of clarain that could not be distinguished from vitrain, though in other samples the clarain had the woody structure mentioned by Stopes. Durain could hardly be obtained pure, while fusain was always easily recognized. Phys. and chem. properties were detd. by crucible heating, elementary analyses, ash and sp. gr. detns., distn. according to Bauer, and CO<sub>2</sub> and CH<sub>4</sub> detns. The appearance of individual constituents of coal dust is discussed.

**The purification of coal.** R. BULMER. *Fuel Econ. Rev.* 8, 6-9(1929).—A review.

**Washing and preparation of coal.** H. D. SMITH. *Fuels and Steam Power* (A. S. M. E. Trans.) 50, No. 23, 25-31(1928).—Both wet-washing and dry-cleaning processes are considered.

**Determination of the moisture content of coal and similar substances.** MANFRED MANNHEIMER. *Ind. Eng. Chem., Anal. Ed.* 1, 154-6(1929).—Pulverized coal is agitated in methanol. A glass floater of the same density as the methanol is placed therein and the temp. adjusted until it just floats. The change of temp. necessary for this compensation is a measure of the H<sub>2</sub>O content. Detns. can be made in 5 min with an accuracy as great as that for any other moisture detn.

**The reducing action of various kinds of coal in water solution.** V. S. KRIM AND S. I. PANCHENKO. *Brennstoff-Chem.* 10, 63-4(1929).—Stadnikov and Proskurnina have indicated (C. A. 20, 3342) that the rank of a coal can be detd. by its adsorptive capacity for Fe(OH)<sub>3</sub> in FeCl<sub>3</sub> soln. The authors present results of exptl. work to show that the action is reduction of FeCl<sub>3</sub> rather than adsorption of Fe(OH)<sub>3</sub>. They contend that many factors (e. g., concn. of FeCl<sub>3</sub>, reaction time, grain size of sample) so affect the results that the method is worthless, at least without careful re-standardization. Reply. G. STADNIKOV AND N. PROSKURNINA. *Ibid* 65.—It is impossible to deny the tendency of coals to adsorb electrolytes and colloids from soln. and to assume that such substances as bituminous coal and coke will reduce Fe(OH)<sub>3</sub> in H<sub>2</sub>O soln. Reply. V. S. KRIM AND S. I. PANCHENKO. *Ibid* 65.—They further contend that FeCl<sub>3</sub> is reduced by bituminous coal and present data to show that ferrous Fe is found in solns. resulting from treatment of the coal with FeCl<sub>3</sub>.

**Modification of Parr's total-carbon determination in coal.** R. E. BREWER AND E. P. HARDING. *Ind. Eng. Chem., Anal. Ed.* 1, 145-8(1929).—Parr's app. has been modified to give better temp. control, eliminate the need for compressed air and make possible greater accuracy because of better control of exptl. conditions. The new app. is pictured and the procedure described.

**The expansion pressure and swelling of bituminous coals.** II. G. LAMBRIS. *Brennstoff-Chem.* 10, 44-50(1929); cf. following abstr.—A method previously described (C. A. 23, 2807) for detn. of the swelling power of bituminous coal during coking is applied to a large no. of coking coals and the results of tests are given in tabular form. The main conclusions are: (1) Swelling is enhanced by rapid heating and also by very fine preliminary grinding of the coal; (2) there is no direct relation between coke yield and swelling; (3) max. swelling is obtained by L.'s method wherein complete enclosure of the coking mass by coke shells is prevented.

**The swelling and expansion pressure of bituminous coal.** PAUL DAMM. *Brennstoff-Chem.* 10, 65-6(1929); cf. preceding abstr.—D. comments on a paper by Lambris (C. A. 23, 2807). The tendency of a coal to swell may be detd. by the crucible test, but this tells one nothing of the expansion pressure exerted during the plastic state of the charge, which in practice tends to force apart oven walls. The following definitions are given with particular application to coking practice: 1. Swelling is that vol. change (referred to the original coal) which a charge undergoes when allowed to expand freely during coking. 2. Expansion pressure is that pressure exerted (kg./sq. cm.) during coking when the charge is confined as by oven walls. A coal may be strongly swelling and still not exert much pressure on the oven walls during

coking. Neither the swelling tendency nor the pressure exerted during coking detrs. the tendency of a charge to stick in the oven. Sticking is caused by failure of the coke to shrink during the last stages of gasification.

J. D. DAVIS

**Study of the degasification of different types of bituminous coal.** P. SCHLÄFFER AND H. RUF. *Schweiz. Ver. Gas u. Wasserfach. Monats-Bull.* 9, 5-11, 47-59, 76-91, 112-23, 149-57 (1929).—The more important work on high-temp. distn. of coal is critically reviewed with special reference to heat consumption. A new *app. for the distn. of coal samples* up to 1 kg., with adjustable final temp., is described. The dependence of quantity and compn. of all distn. products on the carbonization temp. and coal species is demonstrated. With coking coals, the migrating plastic zone is practically impervious to gases, thus separating the charge into two regions of very different degasification conditions. In the central region, only small quantities of gas but large quantities of steam are generated. These wander before the plastic zone toward the center, and escape from the charge in large quantities only shortly before the coking zones come together, thus undergoing secondary decompns. from contact with the highly heated coke layers and retort walls. This decompn. is manifested by a sudden increase in  $H_2$  and delay in the falling off of the  $CH_4$  yield. It depends mainly on the carbonization temp., the kind of coal and the possibility of secondary decompns. The heat consumption varies during the distn. The total heat depends on the final temp. and coal species as well as on the possibility of secondary pyrogenic decompns. The relationships observed by others, between coal and product compns., yields, temps., etc., are confirmed, and, in part, supplemented. The existing knowledge of the fusion phenomena and temp. migrations, during carbonization, also is extended. F. S. G.

**Electrostatic method for determining fusain in bituminous coal.** J. D. DAVIS AND J. A. YOUNKINS. *Ind. Eng. Chem., Anal. Ed.* 1, 165-7 (1929).—The fusain is sepd. in the impure state from the 60-mesh air-dried coal by gravity and subsequently purified in inert gas by an electrostatic field. The purity of the recovered fusain may be checked by the microscope.

H. C. PARISH

**Apparatus for determining the range and degree of plasticity of coking coals.** G. AGDE AND L. V. LYNCKER. *Brennstoff-Chem.* 10, 86-7 (1929).—The app. consists of an electrically heated Cu or Al cylinder in which 2 holes are drilled from the top to admit two 11-mm. tubes, one contg. the coal sample and the other a thermo-element around which coal is also packed. A weighted steel needle rests on the coal to be tested. A thin wire attached to the projecting end of the needle passes over a roller to which a pointer is attached and terminates in a counterweight. A circular scale is provided, so that the softening of the coal on gradual heating ( $5^\circ$  per min.) is indicated by passage of the pointer over the scale. A charge consists of 3 cm. of coal sized between 1 and 2 mm. Before the tube is filled 1.5 cm. of sea sand is placed in the bottom of the tube to absorb tar. From temp. readings at  $5^\circ$  intervals together with indications of the pointer the plastic range of the coal tested can be plotted. J. D. DAVIS

**Apparatus and method for determination of the rate of gasification of coking coals.** G. AGDE AND L. V. LYNCKER. *Brennstoff-Chem.* 10, 89-90 (1921).—A 3-g. sample of the coal (sized to 0.5 to 1 mm.) is gasified at  $1200^\circ$  in a special electrically heated tube and the gas evolved is caught in one of two burets whereby the amount corresponding to each 5-min. interval can be measured. The tube is of glazed porcelain (Barlin, K.-Masse) designed to be gas-tight at  $1200^\circ$ . It is set vertically in a platinum-wound furnace designed for heating at the rate of  $7^\circ$  per min. Gasification curves wherein rate of gas evolution is plotted against temp. are given for raw coal, "oily" and "solid" bitumen and extd. coal.

J. D. DAVIS

**Present and future of chemical utilization of brown coal.** A. THAU. *Brennstoff-Chem.* 10, 41-4 (1929).—There is increased activity in briquetting, briquets being now largely used as generator and producer fuel. For this use they must be uniformly dry; otherwise they fall to pieces during preliminary distn. Furthermore bitumen-rich material must be pulverized before briquetting. Extn. of montan wax is on the wane. The Rolle method of carbonization is gradually being relinquished because of its high installation costs and low capacity. Newer methods involve larger capacity and combination of tar recovery with utilization of coke for power or gas production. Better methods of refining tar are being evolved. Purification of paraffin in one stage has been perfected, but in spite of the import tax, foreign competition has injured the industry. The future of the candle market is uncertain. Household use of "Grude-Koks" is falling off. The Bergius hydrogenation plant at Mersburg may be considered technically successful. This method, however, will probably not entirely replace other ones as at first supposed. As regards complete gasification as a means of

manuf. of city gas, recent studies have demonstrated the possibility of making approx. 2300 cu. ft. of 450 B. t. u. gas of 0.52 sp. gr. from 1 ton of brown-coal briquets.

J. D. DAVIS

**Brown coals and bituminous shales of Hesse and their utilization.** A. SANDER. *Brennstoff-Chem.* 10, 21-6, 141-8(1929).—The history of mining development in the Grand Duchy of Hesse together with production statistics is given. Proximate and ultimate analyses as well as carbonization assay results are given for the more important deposits.

J. D. DAVIS

**Lignite in Alabama.** JELKS BARKSDALE. Geol. Survey of Ala., *Bull.* 33 (1929).—The Ala. lignite occurs in the Cretaceous and Tertiary areas of S. and W. Ala. Numerous outcrop sections and 16 analyses are given.

ALDEN H. EMERY

**Calculating lignite drier with psychrometric chart.** IRVIN LAVINE and R. L. SUTHERLAND. *Chem. Met. Eng.* 36, 425-8(1929).

E. H.

**Characteristics of the bituminous material in peat.** G. I. STADNIKOV and N. G. TITOV. *Zhur. Prikladnoi Khim.* 1, 328-30(1928); cf. *C. A.* 23, 2808.—Exptl. work shows that in the process of formation of peat and coal the org. matter may form not only hydrocarbons but also insol. polymers.

V. KALACHEVSKY

**The acids of montan wax.** HANS TROPSCH and H. KOCH. *Brennstoff-Chem.* 10, 82-6(1929).—Raw montan wax was saponified with KOH in H<sub>2</sub>O soln. under pressure and the soap formed was freed from neutral material by extn. with C<sub>6</sub>H<sub>6</sub>. The acids were then set free and converted into their methyl esters, which were fractionated under 5 mm. pressure. The fractions were now saponified and the acids fractionally pptd. with Mg(OAc)<sub>2</sub>. Besides fatty acids C<sub>25</sub>, C<sub>27</sub> and C<sub>29</sub>, previously found, an acid C<sub>31</sub>H<sub>62</sub>O<sub>2</sub> was identified. Its amount was 4.7% of total acids present. The acid C<sub>30</sub>H<sub>60</sub>O<sub>2</sub> was not present in the wax examd.

J. D. DAVIS

**Progress report of the technical committee of the Natural Gas Association.** G. G. OBERFELL. *Refiner and Natural Gasoline Mfr.* 8, No. 6, 112-8(1929).

J. L. ESSEX

**Natural gas storage practice.** G. M. DAVIDSON. *Refiner and Natural Gasoline Mfr.* 8, No. 6, 102-8(1929).

J. L. ESSEX

**Gas-producer practice.** R. J. SARJANT. *Fuel Econ. Rev.* 8, 30-5(1929).—S. reviews conditions that are essential to efficient operation and describes the Broughton-Hadlington producer. Inasmuch as the selection of a coal, which can be gasified satisfactorily, is preferably confined to neutral or non-coking types, a simple coking test is a ready means of distinguishing suitable fuels. The major problems of gas producer practice lie in the direction of making available for gasification a wider range of fuels.

H. C. PARISH

**Gas-works practice.** H. HOLLINGS. *Fuel Econ. Rev.* 8, 25-9(1929).—The stationary conditions in an intermittently operated type of vertical retort appreciably widen the choice of suitable coals. There is a fairly definite relationship between the CO<sub>2</sub> concn. in the air-free waste gases and the thermal equivalent of gas lost in the setting

H. C. PARISH

**The decomposition of methane, and coke-oven gas in particular, at low pressures by electric discharge.** FRANZ FISCHER and KURT PETERS. *Brennstoff-Chem.* 10, 108-13(1929); cf. *C. A.* 23, 3861.—Orienting expts. were made at atm. pressures and temps. —185 to +750° wherein CH<sub>4</sub>, coke-oven gas and water gas were passed through a high-frequency type ozone tube. Very little decompn. of CH<sub>4</sub> resulted, and the method was changed in that the discharge was passed directly through the gas maintained at low pressures, a Geissler type tube of glass being used. The best conditions for decompn. of CH<sub>4</sub> were: pressure 40 mm. Hg, gas flow 367 l./hr., reaction tube diam. 35 to 60 mm., voltage drop between electrodes spaced at 40 cm. 5000 to 7000 v. room temp. By starting with gas analyzing 2.8% CO<sub>2</sub>, 1.5% illuminants (C<sub>2</sub>H<sub>2</sub> free), 1.2% O<sub>2</sub>, 5.4% CO, 52.3% H<sub>2</sub>, 23.4% CH<sub>4</sub> and 13.4% N<sub>2</sub> a gas contg. 8.5% C<sub>2</sub>H<sub>2</sub>, 67.7% H<sub>2</sub>, and 4.8% CH<sub>4</sub> was obtained by one passage through the tube. The main reaction is considered to be 2CH<sub>4</sub> = C<sub>2</sub>H<sub>2</sub> + 3H<sub>2</sub> — 4000 cal. About 15% of the energy supplied does useful work. Tar pptd. in the reaction tube is easily removed by passing water gas or air through the tube, elec. discharge being maintained. Expts. in which C<sub>10</sub>H<sub>8</sub> was introduced into the reaction tube with H<sub>2</sub> and N<sub>2</sub> showed the reaction C<sub>10</sub>H<sub>8</sub> + H<sub>2</sub> + 5N<sub>2</sub> = 10HCN to take place.

J. D. DAVIS

**Dust and acid removal from boiler flue gases.** J. B. C. KERSHAW. *Power Eng.* 24, 268-71, 275(1929).—An account of methods of treatment.

**Failures in steam boilers.** ANTON POMP and PETER BARDENHEUER. *Mill.*

*Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf 11*, 185-91(1929).—Three sep. cases of failure were investigated. In one case the elastic limit of the rivet had been exceeded. This resulted in brittleness which had been promoted by high temp. and alkyl. in the priming water. In the second case the boiler was too shallow and the mech. specifications for the material were deficient with respect to elastic limit and tenacity. In the third case a fissure had developed from corrosion initially started around the rivets which was promoted by the alkyl. of the priming water. HANS DUUS

**Pyrogenous decomposition of coal tar in presence of hydrogen and under pressure.** V. N. IPAT'EV AND A. D. PETROV. *Zhur. Prikladnoi Khim.* 1, 172-6(1928).—More liquid products are obtained by heating coal tar under pressure of  $H_2$  than by distg. with  $H_3PO_4$ . The yield of low-boiling fractions is also higher.  $H_2$  favors formation of satd. compds. Short heating in  $H_2$  atm. results in decompn. of phenolic ethers, unsatd. cyclic ketones and acids. Aromatics and phenols are formed. Long heating with  $H_2$  converts phenols and satd. cyclic ketones into aromatics and polymethylenes. The max. amt. of liquid products is obtained at 440-60° with excess of  $H_2$  and in presence of catalysts. High-boiling fractions obtained by heating with  $H_2$  have a good odor and stable color and might be used as solvents, lubricants, etc. V. K.

**The methods for the determination of water and steam-volatile solvents in tar and oil.** R. KATTWINKEL. *Teer u. Bitumen* 27, 181-5, 201-4, 217-22(1929).—A review. F. S. GRANGER

**Test for coal-tar pitch in natural asphalt, asphalt from petroleum, and in the presence of colophonium.** F. J. NELLENSTEIJN AND J. C. M. SAUERBIER. *Z. angew. Chem.* 42, 722(1929).—Superior to the diazo and other tests usually applied for the detection of coal-tar products in asphaltum is a test with Millon's reagent, a carefully prepd. Hg nitrate soln. stable for only 24 hrs. Boil 10 g. of material with about 25 cc. *N* NaOH for 20 min., filter, and treat with  $HNO_3$  until slightly alk. Conc. to 5-10 cc., treat 5 cc. with 5 cc. Millon's reagent, and heat the mixt. in a test tube placed in boiling  $H_2O$  30 min. With asphalt or colophonium no color develops, but even 1-2% of coal tar will cause a coloration. W. C. EBAUGH

**The determination of coke yields for the coke plant based on a distillation test.** L. LITINSKY. *Instruments* 2, 239-42(1929).—A glass tube 14 by 530 mm. closed at one end is filled as follows: 20 g. dried powd. coal, 2 asbestos wool plugs, finely divided well-dried fire clay (140 mm.) and an asbestos plug. This is placed in a combustion furnace and connected to a train contg. a cotton-filled tube (to collect tar), a naphthalene-collecting tube, a 0.1 *N*  $H_2SO_4$  wash bottle (to collect  $NH_3$ ), a 1:3 KOH tube (to collect  $H_2S$  and  $CO_2$ ), 5 special paraffin-oil-filled flasks in an ice bath, and a gas-collecting flask. The coke made in practice is equal to a mean between the value from this assay and that from the ordinary crucible method. Tar is slightly less than that obtained commercially. Actual  $NH_3$  output is 10% less than the assay. A. H. E.

**Estimation of the amount of tar coke contained in normal coke.** G. AGDE AND L. v. LYNCKER. *Brennstoff-Chem.* 10, 88-9(1929).—If coal from which the bitumens have been extd. is distd. *in vacuo* practically all of the tar can be removed without such extensive thermal decompn. as to deposit free C. By comparing coke yields obtained in this way with those from the raw coal distd. in the usual manner approx. figures for the proportion of coke normally derived from decompn. of the tars are obtained. Figures given for several coking coals vary from 6 to 8%. J. D. DAVIS

**Review of coke-oven technology during the year 1928.** G. E. FOXWELL. *Fuel Econ. Rev.* 8, 16-23(1929). E. H.

**Development and progress in coke-making equipment.** G. SCHNEIDER. *Brennstoff-Chem.* 10, 2-8, 27-8(1929).—Early coke ovens—the meiler and beehive—are discussed briefly and development of the by-product oven in Germany is dealt with in detail. Cuts of the latest types of combination ovens—Collin, Hinsellman, "Kogag," Koppers, Otto and Still—are given and features of design peculiar to each are noted. The recent tendency is toward ovens of large size. These are regenerative or combination ovens; *i. e.*, they are designed for both rich and lean gas heating. S. deploras the slow development of coke dry quenching, but cites a long list of patents covering dry quenching methods. J. D. DAVIS

**The function of uniformity in iron and steel practice.** F. J. BAILEY. *Fuel Econ. Rev.* 8, 35-7(1929).—The most critical feature in blast-furnace operation is the maintenance of the required temp. in the hearth zone. In Germany regularity in coke quality has been brought about by large-scale blending plants. This has contributed toward a very considerable increase in Fe production of existing furnaces. The effects of grading the size of coke are beneficial as well as charging of whole burden in a more uniform condition. H. C. PARISH

**Sixth Report of the Joint Benzole Research Committee of the National Benzole Association and the University of Leeds.** London, Wellington House: The Natl Benzole Assocn. 212 pp. Reviewed in *Colliery Guardian* 139, 39(1929).

**Fuel for internal-combustion engines.** ÉDOUARD J. L. A. GERME. Fr. 656,773, Nov. 16, 1927. A fuel for internal-combustion engines contains  $\text{C}_{10}\text{H}_8$  50-75,  $\text{C}_6\text{H}_6$  50-25%.

**Fuel for explosion engines.** WALTER STEIGER. Fr. 656,832, June 29, 1928. A fuel for explosion engines is composed of alc., which may contain up to 20% of water, mixed with turpentine oil satd. with  $\text{C}_2\text{H}_2$ . Distn. products of crude petroleum may be added to the mixt. and lysol or a soln. of cresol and neutral soap to ppt. the resins in the turpentine.

**Effecting complete combustion of fuels such as gas.** ARTHUR A. BLANCHARD. U. S. 1,720,757, July 16. An oxidizing material such as Cu oxide is used to assist the combustion and to compensate for temporary deficiencies or excesses in O supply by giving up or taking up O to or from the mixt. supplied for the combustion. An app is described.

**Hydrogenating carbonaceous materials.** C. H. LANDER, F. S. SINNATT, J. G. KING and A. CRAWFORD. Brit. 301,720, Aug. 4, 1927. Coal, lignite, sawdust or similar carbonaceous material is subjected to the action of H at 370-460° under 230-300 atm pressure to effect modification (and partial desulfurization in treating coal) and obtain a thermoplastic product suitable for making fuel briquets which may be used in gas distn. retorts or producers.

**Destructive hydrogenation.** J. M. F. D. FLORENTIN and A. J. KLING. Brit. 302,354, Dec. 15, 1927. In producing products such as hydrocarbons of low b p from materials such as tars, lignites or brown coal, as described in Brit. 253,507 (C. A. 21, 2556), Brit. 263,082 (C. A. 21, 3908) and Brit. 276,007 (C. A. 22, 2479), hydrogenating catalysts are used consisting either of reduced metals such as Fe, Ni or Co or of unstable metal compds. such as suboxides, sulfides or nitrides of the multivalent metals such as W, V, Mo, U, Mn, Fe or Cr. An example is given of the treatment with H under 100 atm. pressure at 380-440° of a mixt. of brown coal and tar from brown coal, in the presence of alumina,  $\text{AlCl}_3$ , reduced Fe and Fe oxide to obtain a liquid product contg. 40% of hydrocarbons distg. under 205°.

**Destructive hydrogenation.** COMPAGNIE INTERNATIONALE POUR LA FABRICATION DES ESSENCES ET PÉTROLES. Brit. 302,683, Dec. 20, 1927. Gaseous products from the destructive distn. of carbonaceous materials are hydrogenated in the presence of hydrogenating gases and catalysts intermediate to purifying operations. An app. and various details of operation are described. Ni may be used as catalyst.

**Destructive hydrogenation of carbonaceous materials.** C. H. LANDER, F. S. SINNATT and J. G. KING. Brit. 302,629, Sept. 17, 1927. Concn. of gaseous and vaporous products in contact with material undergoing hydrogenation in a high-pressure vessel is controlled by withdrawing, through a by-pass, a portion only of the products and passing this portion through a purifying or other treating vessel and thence back to the inlet end of the same or another hydrogenation vessel.

**Destructive hydrogenation of carbonaceous materials.** I. G. FARBENIND. A.-G. Brit. 302,253, June 9, 1927. Hydrocarbon mixts. b. below 200° and contg. mainly aromatic and unsatd. aliphatic and hydroaromatic compds. are obtained by the action of an excess of H (preferably in the presence of catalysts) at temps. above 550° under pressures above 20 atm. on materials such as coals, tars, mineral oils, pitches and their conversion products. Catalysts used should be of a "cracking" character such as elements of the 3rd and 4th groups of the periodic system and elements of the second group in conjunction with Ru chloride. Catalysts such as Mo having also hydrogenat-

ing properties should only be used so that cracking properties predominate as in admixture with compds. of elements of the second and third groups of the periodic system. Various details are given. Cf. C. A. 23, 3074.

**Destructive hydrogenation of carbonaceous materials.** J. A. A. ZACON. Brit. 301,949, Sept. 7, 1927. Carbonaceous material such as coal is purified and emulsified with oil and water and the emulsion is charged into a high-pressure reaction vessel and there subjected to the action of an elec. arc or spark at about 150–200° and under 150 atm. pressure. Various details of procedure and of app. are described.

**Carbonizing bituminous fuel and recovery of by-products.** J. M. RUSBY and W. I. BATTIN. Brit. 301,796, Dec. 5, 1927. An app. is described in which bituminous fuel is carbonized and resulting coal gas, tar and other by-products are recovered, and the coke formed is burned below a steam boiler so that the app. serves as a gas-making plant and a power plant for steam generation.

**Low-temperature carbonization of fuels.** A. ABRASSART. Brit. 302,875, Jan. 12, 1928. Partially distd. or devolatilized fuel is formed into briquets which are then passed continuously through a retort on a flexible conveyor. Various details of the app. used are described. Cf. C. A. 23, 959.

**Low-temperature carbonization of bituminous carbonaceous materials.** I. G. FARBENIND. A.-G. Brit. 301,975, Sept. 19, 1927. Hot gases or vapors (which may be inert or may contain O) are blown through the materials so as to keep the fuel in active movement on its bed, but avoiding combustion or gasification to a greater extent than is necessary to produce a temp. for carbonization (suitably 400–600°). An app. and various details of procedure are described.

**Low-temperature distillation of bituminous material such as coal.** TROCKNUNGS-VERSCHWELUNGS- UND VERGASUNGS-GES. Brit. 301,907, Dec. 9, 1927. The material, in fine granular condition, is spread in layers of a thickness of less than 2 mm. and heated to a temp. not exceeding 380° (suitably on a revolving annular hearth such as described in Brit. 289,137 (C. A. 23, 698)).

**Low-temperature destructive-distillation plant with inclined grate.** WALTHER KOENIGER. Ger. 478,477, Feb. 28, 1925.

**Destructive distillation.** METALLGES. A.-G. Ger. 478,017, Jan. 11, 1924. Relates to processes of the kind in which the fuel descends a shaft in which it is first dried and then distd. To avoid passage of gases from the drying space into the distn. space, or *vice versa*, a gas-withdrawing conduit is arranged in the shaft between the 2 spaces, and the pressure in the conduit is made to correspond to that in the drying or the distn. space, whichever is the lower. Cf. C. A. 23, 3795.

**Hydrocarbons from distillation gases.** CARL STILL. Fr. 657,040, July 5, 1928. In the extn. of hydrocarbons from distn. gases by means of washing oils contg.  $C_{10}H_8$ , the content of  $C_{10}H_8$  in the oil is such that no further absorption of  $C_{10}H_8$  from the gas takes place and is kept at this value during the use of the oil.

**Hydrogenating coal, etc.** ALFRED POTT and HANS BROCHE. Fr. 657,409, June 27, 1928. See Brit. 293,808 (C. A. 23, 1740).

**Hydrogenation of coal, etc.** I. G. FARBENIND. A.-G. Fr. 33,955, Aug. 2, 1927. Addn. to 632,850. In the hydrogenation of coal, tars, mineral oils, etc., the app. coming in contact with the heated org. substances are coated with special steels contg. Co, Mo, W, V or Mn and Ni. Cf. C. A. 23, 1739.

**Hydrogenation of coal, etc.** I. G. FARBENIND. A.-G. Fr. 33,972, Aug. 6, 1927. Addn. to 616,237. In the hydrogenation of coal, etc., pressures of 50 atm. and more are used, using H in movement and in large excess, and having as catalysts active C, or metalloids such as B, Si, P, As, Se, Te or their halogen compds. or elements of groups 4 to 8, particularly of the 6th, *e. g.*, Mo, or their compds. along with elements of groups 2 to 7, or Cu or Au or their compds., the latter with the exception of elements of groups 2 and 3, being present in small amt., or catalysts contg. a small amt. of Ag, or mixts. of Cu with Zn or Cd, free or combined, and also containing B, Al, Si, Ti, V, Ta, Cr, Mo, W or Co free or combined, the last only in the combined state, or their mixts. or a precious metal or Pb, Sn or their compds. on supports of  $MgO$  or  $Cr_2O_3$  may be used.

**Refining coal.** MINERALS SEPARATION, LTD. Ger. 478,065, July 9, 1920. Coal is refined by a froth-flotation process in which a sol. frothing agent such as cresol and a small amt. of an insol. frothing agent such as paraffin oil are used together, suitably in a medium of  $Na_2SiO_3$  soln. If the process is carried out in sea water, the sol. frothing agent can be wholly or partly omitted.

**Coal-distillation products.** THE BARRETT CO. Fr. 657,468, July 12, 1928. See Brit. 294,106 (C. A. 23, 2023).

**Coal-carbonizing apparatus.** EDMUND ROSER. Fr. 657,250, July 10, 1928.

**Separating clay and like material from coal, etc.** CHEMISCHE FABRIK IN BILLWARDER, VORM. HELL & STHAMER A.-G. and F. L. KÜHLWEIN. Brit. 302,082, Feb. 8, 1928. The material is treated with solns. of alkali xanthates and subjected to sepn by fine sieves. An app. is described.

**Use of solvents for obtaining oils, etc., from coal and similar materials.** I. G. FARBENIND. A.-G. Brit. 301,946, Sept. 1, 1927. Coal is preheated in a closed vessel (preferably at "over 100-600°" for several hrs.) under such conditions as not to cause caking and then heated under pressure (suitably 100 atm.) with a solvent such as  $C_6H_6$ , which may dissolve 60% of the coal. The product or mixed materials may be treated with solvents for sepn. of wax or resins or may be destructively hydrogenated or cracked in the presence of activated Al and HCl.

**Cooling apparatus for oil.** KARL WILKE. Ger. 478,168, June 28, 1925. App. is described for directly cooling with water a washing oil which has been used to absorb  $C_6H_6$  from gases and freed from  $C_6H_6$  by distn.

**Montan wax.** I. G. FARBENIND. A.-G. Brit. 302,626, Sept. 15, 1927. Montan wax is bleached (in the absence of HOAc or other org. solvent) by suspending it in an aq. soln. of  $H_2SO_4$  or of a Cr salt (or both), adding a chromic acid soln. and heating to above 100°. Similar treatment is stated to be suitable for bleaching other waxes or paraffin. Various details are given. Cf. C. A. 23, 3074.

**Gas manufacture.** ALFRED AICHER. Ger. 478,459, June 27, 1925. Gas of good quality is obtained from poor fuels such as lignite by a process comprising (1) low-temp. distn. of the fuel to produce gas, tar and semi-coke, (2) conversion of the tar oils to oil gas, (3) mixing the gases from (1) and (2) and adding water gas to the mixt., and (4) thermally decomp. the tar residues from (2) and mixing the gaseous products with the gases obtained in (3).

**Combustible gas from bituminous fuel.** JOHN M. RUSBY and CHARLES W. ANDREWS (to U. G. I. Contracting Co.). U. S. 1,720,403, July 9. Bituminous fuel is charged into a gas producer so as to form a fuel bed with voids between the fuel lumps; the fuel bed is air-blasted while it remains quiescent, to form combustible gas until the top portion of the fuel bed is coalesced and the voids partly eliminated; the air blast is then stopped, the coalesced fuel portion is stirred, more bituminous fuel is added, and the fuel bed is further air-blasted. An app. is described.

**Gas rich in olefins from bituminous coals.** I. G. FARBENIND. A.-G. Brit. 301,775, Sept. 1, 1927. Coals such as brown coal in pulverized or granulated form are rapidly heated to about 800° and the gas and coke formed are rapidly cooled. The coal may be assocd. with inert material such as sand and may be passed by the aid of superheated steam through a Cr-Ni-Fe alloy pipe which is externally heated. Wet coal should be preliminarily dried to avoid the water-gas reaction. Tar formed may be returned to the process for retreatment. An app. is described.

**Purifying gas.** JEAN H. BRÉGEAT. Fr. 656,524, Nov. 10, 1927. Lighting gas is purified by washing with hydroaromatic or alicyclic compds. such as tetralin, decalin or cyclohexanol. The extn. is carried out with heat and the extd. products are sepd. by cooling. Cf. C. A. 23, 2557.

**Treating gaseous hydrocarbons.** EMPIRE GAS AND FUEL CO. Fr. 657,394, June 13, 1928. See Brit. 295,356 (C. A. 23, 2186).

**Treating gaseous hydrocarbons.** EMPIRE GAS AND FUEL CO. Fr. 657,383, May 16, 1928. See Brit. 290,613 (C. A. 23, 846).

**Gas producer.** J. BELLAY. Belg. 355,276, Nov. 30, 1928. Constructional features.

**Gas producer.** MOTORENFABRIK DEUTZ A.-G. Brit. 302,607, Dec. 16, 1927. The temp. in the fire zones of gas-producer plants, having 2 zones in one producer or more than one fire zone in sep. producers, is regulated automatically in accord with the temps. in these zones or the pressures in the air-inlet pipes to these zones. Various structural features are described.

**Gas producer for use with fuel dust.** ALBERT LEDEBUR. Ger. 477,581, June 3, 1925. Details of construction are described.

**Lean gas producer.** J. VAN HEMELRYCK. Belg. 354,660, Nov. 30, 1928. Constructional features.

**Gas-producer operation.** H. C. READING and T. G. TULLOCH. Brit. 302,033, Nov. 16, 1927. The temp. of a suction gas producer is controlled automatically by a thermostat placed in the hot air or steam supply pipe, which operates a valve in this pipe to admit cold air and maintain the temp. of the incoming air and steam constant. Various structural details are described.

**Operating molten-slag gas producers.** HENRI J. F. PHILIPON (to Soc. anon. "l'Air Chaud"). U. S. 1,720,290, July 9. A temp. of about 2000° or higher is maintained in a limited zone adjacent to the bottom of the charge in the gas-generating chamber by delivering an air blast heated to 500° or higher at this zone, so that non-volatile residues of the charge are slagged or liquefied. An app. is described.

**Treating coal gas.** WOLF J. MÜLLER. Austrian 113,333, Jan. 15, 1929. The CO content of coal gas or of mixts. of coal gas with water gas is eliminated by treating the gases with steam in known manner in the presence of  $\text{Fe}_2\text{O}_3$ , and removing the  $\text{CO}_2$  so formed by washing with  $\text{K}_2\text{CO}_3$  soln.

**Coal-gas retorts.** FREDERICK J. WEST, ERNEST WEST and WEST'S GAS IMPROVEMENT Co., LTD. Ger. 477,706, May 5, 1927. A coke-separating device for vertical retorts is described.

**Operating gas retorts.** GAS LIGHT & COKE Co., H. HOLLINGS and J. NEATH. Brit. 302,437, Oct. 6, 1927. The pressure in intermittently charged gas retorts or ovens is automatically controlled to suit conditions at different stages of carbonization and during charging and discharging. Various details of the app. are described.

**Fuel-feeding device for water-gas generators, etc.** POWER-GAS CORP., LTD. and N. E. RAMBUSH. Brit. 302,852, April 13, 1928. A device is provided for cutting off the feed of fuel during certain periods, *e. g.*, during the blow period of a water-gas generator.

**Water gas.** HUMPHREYS & GLASGOW, LTD. Ger. 477,756, Mar. 13, 1925. A water-gas plant is described.

**Apparatus for the thermal decomposition of natural gas.** LOUIS GUMZ. Ger. 478,191, Jan. 12, 1928.

**Oven for producing gas and coke.** HEINRICH KOPPERS and OSWALD PEISCHER. Ger. 478,250, July 1, 1924.

**Tar from coke-oven gas.** F. COOKE. Brit. 301,645, Dec. 2, 1927. Tar is condensed from coke-oven gas and withdrawn from an air-cooled main at a temp. of 160–190° through a branch leading to a seal pot; part of the tar passes to a tank which may be variably cooled and is returned to the end of the bench main in a manner controlled to regulate the temp. of condensation. A plant arrangement and various details of further treatment of the gas and tar to obtain  $\text{NH}_3$ , benzene and creosote oil are described.

**Separating acid from tar.** F. CURT BUNGE. Fr. 651,950, Mar. 29, 1928. The crude tar is emulsified with water and a little soap and treated with a solvent for the acid, such as alk. solns., alc. or acetone.

**Vaporizing tar oil, etc.** KOHLENVEREDLUNG A.-G. Fr. 657,120, July 6, 1928. In cracking or distg. tar oil or tar products, they are finely sprayed on rotating disks heated by circulating gases or steam.

**Coke oven.** J. VAN ACKEREN (to Koppers Co.). Brit. 302,365, Dec. 15, 1927.

**Coke oven.** H. KOPPERS A.-G. (to F. Totzek). Brit. 302,225, Dec. 12, 1927. In a coke oven with regenerator tunnels running the length of the battery, the connecting passages between the regenerators and the heating-flues include a pair of flues running longitudinally beneath the sole of each oven. Various details of construction are described.

**Coke oven (with porous hollow columns in the heating flues for the admission of combustion air).** ADOLF ORT. Ger. 478,066, June 11, 1924.

**Oven for the production of semi-coke and similar products.** SOCIÉTÉ GÉNÉRALE DE FOURN A COKE. Belg. 355,326, Dec. 31, 1928. Constructional features.

**Charging coke ovens.** KOPPERS Co. Brit. 302,188, June 11, 1927. Charging is effected from openings in the roof near both ends of the oven and, subsequently, through an intermediate opening; and smoke and gas generated are withdrawn into gas-collecting mains from the spaces on the 2 sides of the intermediate mound of coal through outlets at both ends of the oven. Various structural details are described. Brit. 302,189 also relates to a coke-oven construction and charging system.

**Leveler bar construction for coke ovens.** JOSEPH VAN ACKEREN and JOHN I. THOMPSON (to Koppers Co.). U. S. 1,720,805, July 16.

## 22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

**Comparison of Russian and American petrolatums.** A. S. VELIKOVSKII AND S. S. NIFONTOVA. *Neftyanoe Khozyaistvo* 15, 477-89(1928).—The following are for American, Grozny and Baku petrolatums, resp.: sp. gr. (60°) 0.820-0.875, 0.880, 0.869; viscosity ( $E_{60^\circ}$ ) 10.34-14.68, 3.94, 10.3; color (Duboscq) 18-157 mm., 21 mm., 9 mm.; acidity (%  $SO_3$ ) 0.0008-0.006, 0.020, 0.051; ash 0.0002-0.0162, 0.371, 0.130, asphaltenes none, none, 0.34%; iodine no. 9-15, 8.12, 3.1; oxygen no. 0.73-4.30, 2.67, 4.45; % paraffin wax 32.88-61.5%, 19.01%, 19.52%. To improve Russian petrolatums by increasing their paraffin content ordinary Grozny petrolatum was dissolved in naphtha (1:1) with initial b. p. 150°, the soln. was cooled from 38° to -10°, the upper layer decanted, and the solvent distd. from the lower layer. A petrolatum of 42° pour test with 26% of paraffin and a consistency of 200 was then obtained which went down 3° after remelting and then remained stable. Surakhanui crude oil also yielded a good petrolatum by the above method.

**Method of preparation of artificial petroleum and of carboniferous decolorizing substances from raw rubber scrap or vulcanized scrap.** H. NISHIDA. *Caoutchouc & gutta-percha* 26, 14625(1929).—A description of the chemistry involved in a recent patent (cf. C. A. 22, 3772).

**Fuel economy in the petroleum industry.** F. SCHWARTZ. *Mon. pétrole roumain* 29, 361-7(1929); cf. *Petroleum Times* 21, 1072(1929).—S. proposes a steam-boiler plant producing steam at about 8 atm. pressure to drive a turbine, the steam entering at full boiler pressure and leaving at 2.5 atm. The turbine operates the elec. generators and the exhaust steam from the turbine is used for processing and heating. The steam necessary for this system is only 60% of that required for ordinary steam-driven pumps, and the cost of the system, including operation, etc., is 64% of the present steam system and 75.5% of the Diesel-engine system.

**Manufacture of automotive and household petroleum specialties.** E. N. KLEM-GARD. *Refiner and Natural Gasoline Mfr* 8, No. 6, 58-62(1929).—Formulas are given for automobile polishes, cleaning fluids, fly sprays, etc., that utilize various petroleum products.

**Volumetric estimation of sulfur in crude petroleum.** GLADYS WOODWARD. *Ind. Eng. Chem., Anal. Ed.* 1, 117-8(1929).—An adaptation of the Nikaido method [cf. *J. Am. Chem. Soc.* 24, 774(1902)], using Pb nitrate soln. to det. the S by the bomb-explosion method. For oils of high-S content, the method is accurate to about 1%, while for oils of low-S content it is accurate to about 3%. Prepn. of soln. and procedure are described.

**Determination of sulfur in petroleum oils.** R. C. GRIFFIN. *Ind. Eng. Chem., Anal. Ed.* 1, 167-9(1929).—In the detn. of S in oil by the O. bomb, part of the S is converted to sulfonic acid and is not pptd. by  $BaCl_2$ . This S can be recovered by refluxing the filtrate from the Ba pptn. with HCl. Mercaptans cannot be correctly estd. by either the bomb or the lamp method.

**Sulfur compounds of shale oil and petroleum.** FREDERICK CHALLENGER. *Chemistry & Industry* 48, 622-6(1929).—Thiophene and its homologs and derivs. have been found in coal tar and shale oil. "Thiophanes" ( $C_nH_{2n}S$ ) were found in Canadian petroleum by Mabery. Persian petroleum has been shown to contain sulfides and mercaptans. The  $H_2S$  contained in Persian oils as they come from the wells is partly oxidized in the air to S. This S probably reacts with the hydrocarbons in the oil to give the S compds. found in the gasoline and kerosene fractions. Part of the thiophene compds. in coal tar and shale oil may originate in this manner. They are probably the product mainly, however, of thermal decompn. of S compds. in the coal or kerogen substance. In what form the S occurs in the coal conglomerate is not known. There is need for study of the S compds. which can be removed from coal by low-boiling solvents. A classified bibliography of 75 references is appended, covering the literature upon S compds. in coal tar, shale oil, petroleum, etc., published 1926-8.

**Report of Committee D-2 on petroleum products and lubricants.** F. A. HULL, et al. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 72, 40 pp.—Tentative revisions of standard methods of test are proposed for viscosity of petroleum products and lubricants and distn. of gasoline, naphtha, kerosene and similar petroleum products. The proposed tentative method for expressible oil and moisture in paraffin wax

is the well-known press method, applicable to crude, semirefined and refined paraffin wax melting at or above 108°F. The results bear no relation to the actual oil content. The proposed tentative method of test for S in motor fuels, naphthas and illuminating oil (lamp method) yields good results if the dimensions of the app. are adhered to closely. The present tentative method of test for pptn. no. of lubricating oil is satisfactory if the naphtha used as a diluent has an aniline point of 58–60°. A new gravimetric method for the pptn. no. is proposed. Results of detg. crankcase diln. of used oils by the steam-distn. method are 3% higher than by the vapor-temp. method. The Sligh method approaches the steam-distn. method. There is material present in used oil which is neither gasoline nor motor oil. The pour points of 10 fatty oils by the standard method were found reliable; the cloud points were found unreliable.

ARTHUR FLEISCHER

**Cracking.** BUTKOV. *Neftyanoe Khozyaistvo* 15, 674–8(1928).—Oil was cracked in the vapor phase in a modified Rittman app. at a pressure of 0.25 to 5 atm. and a temp. of 425° to 575°. The rate of charging was 1.7 g. per min. From 300 g. of Emba solar-oil distillate, 19.7 to 5% gasoline and 0 to 36 l. of gas (per 100 cc. charging stock) were obtained, depending on the temp. and pressure applied. Raising the pressure at const. temp. increases the yield of gasoline and decreases that of gas, while raising the temp. at const. pressure increases the cracking rate of the solar oil and produces more gas. Decalin (b. 187°) yielded 11 l. of gas per 100 cc. when heated at 478° under 5 atm. pressure. Tetralin (b. 205°) cracked very little at 484°, while at 533° compds. b. 130° to 200° were obtained with no appreciable naphthalene or gas formation. At 575° hydrocarbons b. 94° to 200° were formed as well as considerable naphthalene and gas; i. e., dehydrogenation prevailed. When the 150–155° and 170–175° fractions of com. turpentine were cracked at 5 atm. and 460°, up to 7 l. of gas per 100 cc. and a series of liquid hydrocarbons (initial b. p. 56°) were obtained. A mixt. of new products is obtained when individual hydrocarbons are cracked. The temp. affects both the speed and the character of the reaction. A small bomb provided with a pressure gage and thermocouple pocket was used to study the pressure developed by various degrees of cracking. The increase in pressure vs. time when a cylinder oil was heated from 323° to 525° was noted. The reaction is endothermic and the speed passes through a max. and drops off, gradually approaching zero.

A. A. BOEHLINGK

**Progress in cracking.** LEOPOLD SINGER. *Petroleum Z.* 25, 741–8(1929).—A review of recent literature (with 108 references) and patents (with 22 references).

A. A. BOEHLINGK

**The cracking process from the technical and practical point of view.** M. NAPHTALI. *Auto-Tech* 18, No. 5, 8–10(1929).—A review. Cf. *C. A.* 22, 3765.

A. A. B.

**Skimming, cracking, lubricating-oil making from Ranger crude oil.** PAUL TRUESDELL. *Natl. Petroleum News* 21, No. 23, 73, No. 25, 78, No. 26, 80(1929).—This is the method of refining crude oil used by the Trans-Continental Oil Co.

J. L. E.

**Addition of hydrogen chloride to unsaturated cracked gases.** A. F. DOBRYANSKII AND M. NEMTZOV. *Neftyanoe Khozyaistvo* 15, 472–6(1928).—A  $C_3H_6$  concentrate, sp. gr. about 1.6, composed of 65–70% of  $C_3H_6$ , some butylenes, and up to 20% of higher homologs, and less than 3% of  $C_2H_4$ , was subjected to the action of HCl (gas) at a temp. not exceeding 150°, with  $BiCl_3$  as a catalyst. Up to 92.4% of the  $C_3H_6$ , 90% of the  $C_4H_8$ , and 8.5% of the  $C_2H_4$  reacted with the HCl. The catalyst was poisoned quickly.

A. A. BOEHLINGK

**Roumanian refineries.** H. E. CASSIDY. *Refiner and Natural Gasoline Mfr.* 8, No. 6, 69–73(1929).—A survey is made of the refining business in Roumania.

J. L. ESSEX

**Dephlegmators.** K. V. KOSTRIN. *Neftyanoe Khozyaistvo* 14, 762–8(1928).—A lab. investigation of Bibi-Eibat crude oil indicates that a better sepn. of fractions and a more efficient utilization of equipment can be effected by passing the vapors in dephlegmators downwardly, instead of upwardly as usual.

A. A. BOEHLINGK

**Vacuum distillation.** S. A. VISHETRAVSKII. *Neftyanoe Khozyaistvo* 14, 769–71(1928).—When fuel oil is distd. in vacuum stills, some cracking is apt to occur, principally in the first and last stills. The overheating of the oil can be prevented by (1) the use of more steam, which acts as a carrier, and (2) by using the oil in finely divided form, which can be effected by atomizing it into the still.

A. A. BOEHLINGK

**Handling vacuum-distilled wax-bearing products.** EARL PETTY. *Refiner and Natural Gasoline Mfr.* 8, No. 6, 62–8(1929).

J. L. ESSEX

**Aluminum chamber oven for low-temperature assay of bituminous materials.** A. WEINDEL. *Brännstoff-Chem.* 10, 67–9(1929).—The oven is rectangular (60 cm,

long by 10 cm. wide and 11 cm. high) and is of cast Al. A cast door fits into one end and is held in place by a screw clamp; a vapor off-take is provided at the other. An inlet for superheated steam is placed at the oven top near the charging end. The oven is mounted on steel legs which also support an asbestos-lined sheet-steel mantle and 3 gas burners for heating. The charge of coal used is about 5.3 kg. The app. is made by Andreas Hofer, Mulheim-Ruhr.

J. D. DAVIS

**U. S. motor gasoline specifications changed and a new grade established.** J. C. CHATFIELD. *Natl. Petroleum News* 21, No. 25, 27(1929).—The Federal Specification Board has revised the distn. specifications for U. S. Motor Gasoline and also published specifications for a new grade of gasoline to be known as Motor Fuel V which is more volatile than the U. S. Motor Gasoline. In the U. S. Motor Gasoline specification, the 20%-point has been dropped and the substitution of a max. and min. 10%-point has been instituted. Requirements now are that when 10% has been recovered in the receiver the thermometer shall not read more than 80° nor less than 50° provided that for each percent of distn. loss less than 4% detd. in the A. S. T. M. distn., the min. temp. requirement shall be lowered 3°. Gasoline which is to be stored in tropical climates has a min. 10%-point of 60°. The 50%, 80% and end points were not altered. The substitution of the min. 10%-point was made to avoid the possibility of vapor locking. The U. S. Motor Gasoline specifications which have been adopted by 12 states will automatically be changed in 6 of these 12 states. The others will perhaps have to ratify the changes. As a substitute for a winter gasoline, the board adopted a new specification for U. S. Motor Fuel V. The requirements for this fuel are that the 10%-point shall not be more than 65° nor less than 50° with the same correction for distn. loss as adopted for U. S. Motor Gasoline. The 50%-point shall not be more than 125°; the 90% point shall not be more than 180°; and the end point shall not be higher than 205° and at least 95% shall be recovered. The S and corrosion requirements are the same as those for U. S. Motor Gasoline.

J. L. ESSEX

**American unblended gasolines.** S. A. VISHETRAVSKII. *Neftyanoe Khozyaistvo* 16, 59-61(1929).—A distn. chart of American casinghead, straight-run and cracked gasolines and a chart of Russian com. gasolines are given for comparison.

A. A. BOEHLINGK

**Stabilizing Grozny casinghead gasoline.** A. N. SAKHANOV AND A. I. DOLADUGIN. *Neftyanoe Khozyaistvo* 15, 464-71(1928).—Casinghead gasoline was stabilized in an app. having the following features: unstabilized gasoline was introduced at the middle point of a tower filled with Raschig rings of about 1-in. size. The temp. at the bottom of the tower was kept at 60-70° by a steam coil. The stabilized gasoline was withdrawn from the bottom and passed through a cooler. The vapors were condensed by a condenser in the upper part of the tower and the condensate was sprayed over the Raschig rings. The pressure of the system was kept at 1-2 atm.; a higher pressure produced an unstable gasoline.

A. A. BOEHLINGK

**Results of the exploitation of the first gasoline-kerosene plant in Baku.** K. V. KOSTRIN. *Azerbeidzyanskoe Neftyanoe Khozyaistvo* 1928, No. 8/9, 40-60; No. 12, 38-50.—Details are given of the performance of the "second" battery, furnaces, tubular preheaters, evaporators, rectifying columns, steam boilers, pumps, the distribution and consumption of steam, the efficiency of furnaces and tubular preheaters with evaporators. A list of 68 references is given.

A. A. BOEHLINGK

**The effect of gum in gasoline.** V. VOORHEES AND J. O. EISINGER. *J. Soc. Automotive Eng.* 24, 584-92(1929).—See C. A. 23, 2286.

J. L. ESSEX

**Economic fuel volatility and engine acceleration.** D. B. BROOKS. *J. Soc. Automotive Eng.* 24, 609-16(1929).—The results of tests to det. the effect of the American Society for Testing Material (A. S. T. M.) 50%-point on acceleration and on the most economical fuel volatility from the standpoint of acceleration are given as a continuation of previously reported tests. The effect of the A. S. T. M. 50%-point on engine acceleration or on the quantity of fuel required to give the same acceleration as the standard U. S. Motor Gasoline appears to be negligible except under summer-operating conditions, in which case the acceleration improves and the quantity of fuel consumed decreases with increase in the A. S. T. M. 50%-point, unless some special accelerating device is provided. Current practice in carburetor adjustment makes it possible for some increase in fuel consumption to follow an increase in the A. S. T. M. 50%-point. Tests were run with manifold temps. from -10° to 100°, which represent the extremes of winter warming-up and summer-driving temps. The results show a consistent variation in the relative acceleration obtained with the 4 fuels tested as the manifold temp. varied. The test engine used was a 3 $\frac{1}{8}$ "  $\times$  4 $\frac{1}{2}$ ", 6 cylinder, 3-port overhead valve, 1926 model, equipped with a Sprague elec. dynamometer and operated to dupli-

cate level road conditions in high gear. The semi-automatic spark advance was set to give optimum spark advance at the mixt. ratio for max. power at the mean speed of the range of the acceleration tests. The 4 fuels used showed A. S. T. M. 50% points of 105°, 122°, 140° and 165°, as against 137° for U. S. Motor Gasoline. At manifold temps. of -10°, engine speeds of 300-700 r. p. m., and air-fuel ratio of 12.5 to 1, there is practically no difference between the 4 fuels; at manifold temps. of 10°, engine speeds of 300-700 r. p. m., and air-fuel ratio of 10.2 to 1, the accelerations are in the reverse order of the 50%-point volatility; at a manifold temp. of 90°, engine speeds of 300-700 r. p. m., and air-fuel ratio of 16.5 to 1, the accelerations are in direct order of the 50%-point volatility.

J. L. ESSEX

**Effects of knock-suppressing and knock-inducing substances on ignition and partial combustion of certain fuels.** RAYMOND E. SCHAAD AND CECIL E. BOORD. *Ind. Eng. Chem.* 21, 756-62(1929).—Hot-wire ignition curves were detd. for toluene, isoamyl acetate and kerosene between the upper and lower limits of inflammability. The current required by an electrically heated Pt wire for ignition of the most easily ignitable mixt. of air and the above substances was increased by the addn. of a knock suppressor such as PbEt<sub>4</sub>, PbMe<sub>4</sub>, SeEt<sub>4</sub> and aniline. Addn. of knock inducers, such as isoamyl nitrite, nitrobenzene, and propyl nitrite, decreased the required current. The work was repeated with a break-spark app; knock suppressors and inducers had no effect. The minima of hot-wire ignition curves are near to the calcd. temp. for combustion to CO, while the minima for the break-spark curves correspond to the calcd. temp. for combustion to CO<sub>2</sub>. The difference is probably due to pre-ignition in the former app.; knock suppressors decrease such pre-ignition combustion while knock inducers increase it.

ALDEN H. EMERY

**Capillarity of lubricating oils.** N. A. BUTKOV. *Izvestiya Teplo-Tekhn. Inst. (Trans. of the Thermo-Techn. Inst. (Russia))* No. 5, 29-31(1928).—Viscosities in abs. units according to Ostwald are as follows:

	80°	100°	184°	212°	284°
Vapor "L" . . .	0.652	0.294	0.0446	0.0292	0.013
Vapor "M" . . .	0.6675	0.334	0.0483	0.03105	0.01395
Vapor "T" . . .	0.825	0.428	0.0558	0.0364	0.0156
Viskozoin 3 . . .	0.4415	0.1973	0.03306	0.02134	—
Viskozoin 7 . . .	1.092	0.5337	0.06288	0.03967	0.0180
Viskozoin 10 . . .	1.454	0.6157	0.0692	0.04185	0.0180

Surface-tension measurements gave somewhat higher values at 21° for the Viskozins than for the Vapor oils, indicating lower stability and poorer lubricating qualities. The ratio of power of adhesion to surface tension gives the true indication of the lubricating quality of an oil. Certain Russian and American oils are compared in this respect. Acid treatment of an oil lowers its capillarity, increases the angle of contact, and so reduces the lubricating value. Addn. of oxidized vegetable oils decreases the angle of contact.

A. A. BOEHLINGK

**Apparatus for testing the dilution of lubricating oil in the automobile and airplane motor.** H. KIEMSTREDT. *Chem.-Ztg.* 53, 459(1929).—A portable app. provides for steam-distg. the mixt. of motor fuel and lubricant, and condensing and measuring the oil distillate. The still consists of an outer cylinder contg. H<sub>2</sub>O, to be heated electrically, and a container for the oil sample fitting tightly into the upper part of the cylinder. Tubular openings in the bottom of the oil container lead the steam upward through an inverted U and deliver it near the bottom of the oil sample. The condensate is collected in a measuring tube which connects by a bent tube with a cylinder. The motor fuel distd. off remains in the measuring tube and the specifically heavier H<sub>2</sub>O passes over into the cylinder.

E. E. CRANDAL

**Oxidizing lubricating-oil bottoms.** A. D. DEMCHENKO AND C. N. OBRVADCHIKOV. *Netnyanoe Khozyaistvo* 15, 360-6(1928).—A charge of 263 kg. of asphaltic bottoms was placed in a vertical still, heated to 235-252°, and blown with air for 19¼ hrs. 490 l. of H<sub>2</sub>O, 70 l. of emulsion, and 65 l. of distillate were collected in the process of oxidation. The gases obtained contained an av. of 97.6 N<sub>2</sub>, 0.04% CO<sub>2</sub>, 1.6% O<sub>2</sub> and 0.7% of combustible gases. The acidity of the distillate collected increased with time. The quantity of resins present in the bottoms did not change in the first 10 hrs. The oil content decreased and that of asphaltenes increased. The second 10 hrs. showed a very slow decrease in oil, the resins decreasing rapidly while the asphaltenes increased. The oxidation process required 4580 cu. m. of air. The heat of the oxidizing reaction to obtain a pitch m. 47° is calcd. at 48 cal. per kg. of bottoms. The total heat required for the process is 2½ times greater than that required by the formation of H<sub>2</sub>O

in the above process. This is explained by the cracking reaction, splitting off of  $H_2$ , etc.

**Insulating oils.** G. STADNIKOV AND Z. VOZZHINSKA. *Petroleum Z.* **25**, 651-8 (1929); cf. *C. A.* **22**, 4240.—When an oil is oxidized which contains sulfonic acids or their salts and which has not been freed entirely from resinous substances, acids, alcs. and carbonyl compds. are formed which are condensed with the resins to colloidal compds. of high mol. wt. This change prevents sludge from being formed immediately; the new compds. remain in the oil because the resins act as protective colloids. This oil is frequently passed in inspections, its acid no. being low because the acid enters the condensation products. It is unstable and ppts. sludge after the resinous substances have been consumed. The acid no. then rises. An oil contg. sulfonic acids and their salts but no resins forms sludge very rapidly. This reaction may be retarded when untreated distillates are added because of the presence of resins in the m. Numerous expts. confirming this theory were made. Conclusion: Most of the transformer oils contained traces of sulfonic acids formed during treating. The acid no. is not a criterion of the oxidizability of the oil. The oil must be very thoroughly washed with water after treating, to remove the last traces of sulfonic acids, and finally filtered through an adsorbent. The degree of purity can be checked by adding small quantities of  $AcH$  and  $AcOH$  and heating. The presence of even very small quantities of sulfonic acid is shown by a darkening of the oil.

**Nomenclature of various crude-oil products.** ANON. *Petroleum Z.* **25**, 858 (1929).—A table gives the names used in 20 countries.

**Lord Kelvin's law applied to mineral-oil fractions.** M. RAKITIN. *Neftyanoe Khozyaistvo* **15**, 493-7 (1928).—Kelvin's law is applied to bubble towers.

**Emulsified and saponified oils. IV.** V. LEOPOLD SINGER. *Petroleum Z.* **25**, No. 19, Motorenbetrieb u. Maschinen-Schmierung sect. 7-10; No. 24, 9-10 (1929); cf. *C. A.* **23**, 2560.—A review of the literature with 55 references to papers and patents.

**Manufacture of transformer and switch oils.** TYPKE. *Petroleum Z.* **25**, 819-24 (1929).—A review of refining and testing methods for transformer and switch oils including 33 literature references.

**Contribution to the determination of the tar number in transformer and switch oils.** EUGEN LOCHER. *Chem.-Ztg.* **53**, 470 (1929).—Heat 50 g. of the oil for 24 hrs. at  $120^\circ$  with 10 cc. of  $NaOH$  soln. made by dissolving 7 g. of  $NaOH$  in 100 cc. of  $H_2O$ ; and, without sepg. the  $NaOH$  from the oil, proceed as with the referee method. Results agree fairly well with those yielded by the longer, more expensive process.

**Making cutting and soluble oils.** H. L. KAUFFMAN. *Oil and Gas J.* **28**, No. 4, 46, 75 (1929).—Cutting oils are usually made by compounding mineral oil with a smaller proportion of lard oil. Specifications of a no. of cutting oils on the market are given. Soap in a  $H_2O$ -alc. solvent commonly forms the base of sol. cutting oils. For example, a mixt. of Na oleate 40%, rosin acids 35%, alc. 10-11%,  $H_2O$  14-15%, may be combined with a mineral oil in the proportion of 1 to 4. The quantity of  $H_2O$  to be used depends upon the proportion that gives the most stable emulsion.

**Toluene in the oil of Maikop.** B. E. DOLGOV. *Zhur. Prikladnoi Khim.* **1**, 287-91 (1928).—About 1% of toluene is present in the Maikop crude oils, from which it can be sepd. by fractional distn.

**Treating oil by use of chemicals.** R. T. BRIGHT. *Oil and Gas J.* **28**, No. 5, 40-1, 80-1 (1929).—Dow (*C. A.* **19**, 2561) divides the chemicals used for treating oil emulsions into 6 classes according to the manner in which they affect the protective film around the  $H_2O$  globules. Class 4, the compds. that help to break the protective film by their tendency to form the opposite type of emulsion, are considered best for treating cut oil. In a plant described for treating with chemicals of this class, a force-feed pump, preferably, introduces the chem. into the oil as close to the well as possible and before the oil passes through the separator. Where the vol. and rate of oil flow warrant it, better mixing of the chemical with the oil is attained by introducing 1 or 2 joints of baffled pipe into the line. After mixing, the emulsion is heated, usually to  $120$ - $150^\circ F.$ , either by passing through a boiler or heater before it goes to the wash tank, or by warming the water to be used for washing. Most of the emulsion is broken in the tank, where agitation is kept to a min., and the water and unchanged emulsion are drawn off at the bottom. The unchanged emulsion is recycled and the oil goes to a settling tank and finally to storage.

**Iodine number of turpentine oil.** CYRIL KRANZ, VLADIVOJ HRACH AND IVAN FRANTA. *Chem. Obzor* **3**, 365-7 (1928).—Diagrams obtained by plotting I nos. against

the amt. of oil used, show that with increasing concn. of I soln. the I nos. increase till max. of 370–380 is reached. It is recommended, therefore, to weigh approx. 0.1 g. of turpentine oil and treat this, keeping all other conditions as prescribed by Hübl's method, with an I soln. of which 25 cc. would correspond to about 100 cc. 0.1 N  $\text{Na}_2\text{S}_2\text{O}_4$ .

**Analyses in oil absorption operation.** W. W. ROBINSON. *Oil and Gas J.* 28, No. 3, 54, 182, 184, 186, 188, 190, 192, 195(1929).—An effort is made to show how the principles of phys. chemistry and mathematics can be applied to the operation of a natural gasoline absorption plant. JAROSLAV KUČERA

**Selective adsorption of oil tars.** A. F. DOBRYANSKII. *Neftyanoe Khozyaistvo* 14, 780–95(1928).—The selective adsorption of tarry substances by adsorbents is due to the size and the internal surface of the pores of the adsorbing material. Compds. with large mols. cannot enter small pores and are not adsorbed to the same extent as small mols. If the tar mols. enter the pores, the oil has a brighter appearance. The size of the pores of silica gel can be changed by treatment with metal oxides, followed by drying and dissolving the oxides with  $\text{HNO}_3$ . The oxides with the highest mol. wt. give the largest pores. The adsorptive power of various adsorbents after they were heated to different temps. was studied. E. E. CRANDAL

**Transfer on tube and tank battery makes 2000-hour runs a rule.** PAUL TRUESDELL. *Natl. Petroleum News* 21, No. 26, 78(1929). A. A. BOHRLINGK

**Determination of the specific gravity of asphalt by means of a hydrometer.** HUGH R. BERRY, EDISON H. SMITH AND F. R. LANG. *Ind. Eng. Chem., Anal. Ed.* 1, 164 (1929).—Sp. gr. of asphalt can be detd. quickly by heating a sample to 300° F. and inserting a hydrometer. A table is given for converting the ° A. P. I. read to sp. gr. at 60° F. J. L. ESSEX

**Wood distillation still prospers in Southern States.** NORMAN W. KRASE. *Chem. Met. Eng.* 36, 397–8(1929).—Operation of a plant of the Tennessee products corporation is described. E. H.

**Liquid fuels (GENSKE) 21.** Progress in technology and organization of the Polish chemical industry [work on separation of petroleum emulsions] (ZAMOYSKI) 13. Test for coal-tar pitch in natural asphalt, asphalt from petroleum, and in the presence of colophonium (NELLENSTEIJN, SAUERBIER) 21. Brown coals and bituminous shales of Hesse and their utilization (SANDER) 21. The hydrogenation process of the I. G. Farbenindustrie A. G. (ANON.) 21. C ratios as an index of oil and gas in Western Canada (JONES) 8. Dialkyldiaryllead compounds. Anti-knock studies (GILMAN, BALASSA) 10. Replaceable bases in the shales and clays underlying petroliferous strata (TAYLOR) 8. Utilization of mineral oils for thermal treatment of steels (ROY) 9. Apparatus for the decomposition of hydrocarbons (Fr. pat. 657,118) 9. Hydrogenation [of mineral oils] (Fr. pat. 33,955) 21. Separator for oil and water (Austrian pat. 113,339) 1. Naphthenic acid [from petroleum oils or fractions] (U. S. pat. 1,720,821) 10. Montan wax [bleaching paraffin] (Brit. pat. 302,626) 21. Emulsions of oils (Brit. pat. 302,761) 13.

**Industrial plant lubrication.** Philadelphia: E. P. Houghton & Co. 60 pp. Reviewed in *Rubber Age* 25, 318(1929).

**New and Revised Tag Manual for Inspectors of Petroleum.** Edited by R. M. WILHELM. New York: C. J. Tagliabue Mfg. Co. 120 pp. \$2. Reviewed in *Instruments* 2, p. 19 of advertising section (1929).

**Petroleum distillation.** N. V. BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 302,346, Dec. 15, 1927. In distg. crude petroleum, volatile acid ingredients which are readily emulsifiable with caustic alkalis are fixed (either in the fractions in which they occur or in the undistd. oil) by adding a base such as NaOH, KOH or lime. The fixed ingredients are set free after distn. by adding acids such as HCl or  $\text{H}_2\text{SO}_4$  to the distn. residues. Examples are given of the treatment of Venezuelan crude asphalt. Various details and auxiliary treatments are described.

**Purifying petroleum distillates with liquid sulfur dioxide.** ALLGEMEINE GES. FÜR CHEMISCHE INDUSTRIE. Brit. 301,955, Sept. 9, 1927. After treatment with, and removal of, liquid  $\text{SO}_2$ , a distillate such as illuminating oil is treated with an alk. soln. of Pb oxide to which S may be added. Reference is also made to successive use of liquid  $\text{SO}_2$  and  $\text{H}_2\text{SO}_4$ .

**Cracking hydrocarbons.** N. V. BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 302,349, Dec. 16, 1927. Cracking is effected in the presence of halogens or halogen

compds. (including I and its compds. when gaseous hydrocarbons are treated but not when liquids are treated). The halogen compds. may contain H, S, P and O and activators such as Cu, Fe or their salts, O or S may be added. Propane heated with I at 575° yields a product contg. 15% of unsatd. compds.

**Cracking hydrocarbons and resultant products.** SOCIÉTÉ D'ÉTUDES ET RÉALISATION "ERÉAL." Belg. 356,044, Dec. 31, 1928. The cracking is carried out at a relatively const., but much lower, temp. (800°) than that generally used. An app. is specified.

**Manufacture of mixtures of hydrocarbons.** SOCIÉTÉ D'ÉTUDES ET RÉALISATION "ERÉAL." Belg. 352,537, Dec. 31, 1928. An app. is specified embodying heat-recovery features in the cracking of hydrocarbons.

**Manufacture of mixtures of hydrocarbons.** SOCIÉTÉ D'ÉTUDES ET RÉALISATION "ERÉAL." Belg. 356,043, Dec. 31, 1928. App. embodying heat-recovery features in the cracking of hydrocarbons.

**Improvement in the process of manufacture of mixtures of hydrocarbons.** SOCIÉTÉ D'ÉTUDES ET DE RÉALISATION "ERÉAL." Belg. 355,302, Jan. 31, 1929. The main reaction is regulated by means of an auxiliary reaction, the products of which take part in the main reaction and which itself depends on the main reaction.

**Distilling hydrocarbon oils.** CLIFTON J. PRATT. Fr. 657,085, July 4, 1928. An app. is described for the conversion of hydrocarbon oils to a state possessing max. value as motor fuel, the oils being heated in successive phases, the products of the different phases being mixed and the mixt. fractionated.

**Cracking hydrocarbon oils.** STANDARD DEVELOPMENT Co. Brit. 302,211, Sept. 12, 1927. In the operation of a cracking plant as described in Brit. 274,763 (C. A. 22, 2267) comprising a cracking coil, digester drum, still and dephlegmator, crude oil is first injected into the still, vapors produced are fractionated in the dephlegmator and condensate from the bottom of the latter is led to the cracking coil and digester. Numerous details of app. and procedure are described.

**Cracking hydrocarbon oils.** STANDARD DEVELOPMENT Co. Brit. 302,415, Sept. 22, 1927. The oil is passed under pressure and at high velocity through a heated coil and thence to a digestion drum maintained at the same temp. and pressure by introducing addnl. oil of appropriate temp. along with the heated oil at the inlet of the drum. Various details of the app. are described. Cf. C. A. 23, 3569.

**Cracking oils in liquid phase.** JOHN C. BLACK. U. S. 1,720,070, July 9. A confined stream of oil is heated under superatm. pressure (suitably in a pipe coil) to crack the oil; the temp. of the oil is measured by pyrometers at different places along the stream and oil is injected at points in the stream where fluctuations in temp., as indicated by the pyrometers, are observed, in order to maintain the oil in liquid phase. An arrangement of app. is described. Cf. C. A. 23, 4060.

**Extracting oil from schist.** NAT H. FREEMAN. Fr. 656,542, June 27, 1928. See Brit. 291,475 (C. A. 23, 1261).

**Recovering entrained oil from filter-press cake.** GEORGE F. OLSEN. U. S. 1,720,144, July 9. In order to recover lubricating oil having a Saybolt universal viscosity in excess of 150 sec. at 38° from a filter-press cake in which the oil is entrained, a lubricating oil of a viscosity between 75 sec. and 150 sec. is forced through the cake *in situ*.

**Pressing wax-containing oil.** FREDERICK W. SULLIVAN, JR., W. J. MCGILL and HARRY L. WALKER (to Standard Oil Co. of Ind.). U. S. 1,720,300, July 9. Wax-bearing hydrocarbon oil is forced through a filtering surface to build up a cake of wax on the surface, and oil is then removed from this wax cake by forcing water through it at a temp. below the m. p. of the wax. An app. is described.

**Heat-interchange apparatus suitable for use in oil refining, etc.** EDWARD B. McCABE and GUY C. CHAMBERLAIN (to Carbondale Machine Co.). U. S. 1,720,912, July 16. Structural features.

**Oil filter suitable for use on internal combustion engines.** EDWARD R. HEWITT (to International Motor Co.). U. S. 1,720,475, July 9. Structural features.

**Detection of water in oil.** MAX BUCHHOLZ. Ger. 477,639, July 4, 1926. Substances which evolve gas in presence of water are added to the oil and the buoyancy of the bubbles so formed is used to actuate a mechanical or elec. contact device.

**Purifying oil gas.** C. CHILOWSKY. Brit. 302,292, Dec. 13, 1927. Gaseous products produced by the partial combustion of oil gas in air are passed upwardly over inclined or vertical water-cooled metal surfaces down which the condensation products trickle. Details of the app. used are described. Cf. C. A. 23, 693.

**Condenser for purifying oil gas.** C. CHILOWSKY. Brit. 302,370, Dec. 15, 1927. Structural features.

**Oil-gas plant for use with vehicle engines.** C. CHILOWSKY. Brit. 302,322, Dec. 14, 1927. Structural features.

**"Petrol-air gas" generator.** WILLIAM A. CHAMBERLAIN. U. S. 1,720,539, July 9. Structural features.

**Apparatus for recovery of gasoline or other volatile substances from gaseous mixtures such as natural gas.** MASATOSI OKOCHI. U. S. 1,721,033, July 16. Various details are described of a plant comprising adsorption towers, compressor, coolers, etc. Solid adsorbents such as silica gel or C may be used in the towers.

**Apparatus for recovery of oil and gasoline from gas from wells.** IRWIN L. DUNN and LESLIE C. MINGUS (to Dunn & Lewis). U. S. 1,721,010, July 16. Various structural features are described.

**Treating organic materials such as oils or tars electrochemically.** CARLO LONGHI. U. S. 1,720,910, July 16. Portions of material such as crude oils or tars in liquid form, within a body of the liquid, are subjected to recurring elec. arc discharges of high temp. and the resulting gaseous products are quickly sepd. after each arc discharge and before the effect of the succeeding discharge becomes unfavorable with respect to the compn. of these gaseous products. The  $C_2H_2$  content of the gas may thus be maintained at high proportion. An app. is described suitable for producing  $C_2H_2$ , which may be sepd. or polymerized to form  $C_6H_6$ , etc.

**Lubricating oils.** HUGH L. CALLENDAR, ROBERT O. KING and ERNEST W. J. MARDLES. Fr. 657,377, May 2, 1928. See Brit. 295,230 (C. A. 23, 2291).

**Lubricating oils.** SUN OIL CO. Fr. 657,368, Mar. 16, 1928. Lubricating oils of improved properties are obtained by distg. lubricating fractions from crude oil in a system closed against O, passing the oil through a series of vaporizers in which it is distributed over large surfaces and brought into contact with Hg vapors in such a way as to avoid cracking, progressively higher fractions being sepd. in successive vaporizers. Odor-producing gases are sepd. by reflux condensation under vacuum of the sep. distillates and causing the oil to flow under very high vacuum over large surfaces. An app. is described.

**Filter for lubricating oils, etc.** GEORGE H. GREENHALGH (to Ernest J. Sweetland). U. S. 1,721,250, July 16. Structural features.

**Apparatus for reclaiming used lubricating oils by settling, filtration and evaporation of volatile substances.** CLARK F. BARB. U. S. 1,721,328, July 16.

**Insulating oil for transformers, switches, etc.** SIEMENS-SCHUCKERTWERKE A.-G. Brit. 301,876, Dec. 7, 1927. In distg. oil for use as insulation, local overheating is avoided so as to prevent the formation of cracked products. The distn. may be effected in closed receptacles through which Hg vapor is passed.

**Furnace for melting bitumen in drums.** ROBERT BREINING. Ger. 478,208, Apr. 14, 1928.

**Emulsions of asphalt, oils, rubber, etc.** N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 301,805, Dec. 5, 1927. Emulsions of materials such as asphalt, pitch, tar, wax, mineral or vegetable oils, paraffin or rubber are stabilized by adding sufficient stabilizing agent (such as casein or other suitable protective colloid or sulfonic acid) to prevent pptn. during subsequent treatment and then treating the mass with an electrolyte (such as a dil.  $AlCl_3$  soln.) in the presence of finely divided substances (which may be formed by reaction between alkali present and a portion of the electrolyte).

**Phenols from beechwood-tar oils.** HERMANN SUIDA and ANTON WACEK. Austrian 113,324, Jan. 15, 1929. Heavy beechwood tar oils and their fractions are heated with concd. HCl at  $180^\circ$  under pressure, whereby the phenol ethers in the oil are decompd. and a mixt. of phenols is obtained which may be sepd. in known manner. Examples are given.

**Saccharification of wood.** E. HAGGLUND (to Holzhydrolyse A.-G.). Brit. 302,313, Dec. 14, 1927. The saccharification product obtained by the action of HCl on wood is freed from traces of acid by wet-grinding it with an oxide or hydroxide of an alk. earth metal (suitably in a porcelain ball mill), immediately centrifuging and washing with a small quantity of water. The waste liquors may be fermented or "worked into yeast."

## 23—CELLULOSE AND PAPER

CARLETON E. CURRAN

**Portuguese eucalyptus plantations and their use in cellulose fabrication.** OTTO CYREN. *Svensk Pappers-Tid.* 32, 272-7(1929).—The eucalyptus plantations at Abrantes, Comporta and Caima are described. Pulp made from eucalyptus is compared with

that made from spruce. In spite of the shortness of the fiber it forms a satisfactory substitute, especially when mixed with longer-fibered pulp. W. SEGERBLOM

**The utilization of tropical fiber-producing plants.** CARL G. SCHWALBE. *Z. angew. Chem.* **42**, 713-7(1929).—Reasons for not working up tropical plants by methods that have proved successful in the temperate zones are pointed out, and the recommendation is made that bamboo be converted into semi-pulp, shipped to Europe and there used to replace a part of the wood pulp now required. W. C. EBAUGH

**The enzymic decomposition of cellulose (wood) and cotton.** O. FAUST AND P. KARRER. *Helv. Chim. Acta* **12**, 414-7(1929).—The decompn. of wood pulp (87%  $\alpha$ -cellulose) by snail cellulase, prepd. for the manuf. of rayon or cotton yarn is accelerated by mercerization (cf. Karrer, *C. A.* **21**, 493) but is not affected by bleaching or, with the rayon cellulose, by a short subsequent ripening process. A longer ripening period (4 days) apparently retards the decompn. Cotton mercerized under tension is decompd. to a lesser degree than that mercerized under no tension. In this connection, x-ray examns. show very little, if any, change in the structure diagram of cellulose mercerized under strong tension and a great change when mercerized under no tension. C. E. HRUBESKY

**The molecular weight of cellulose.** I. K. HESS. *Rec. trav. chim.* **48**, 489-91(1929).—H. believes that the mass action equation which assumes the kinetic independence of the  $C_6H_{10}O_5$  group is valid and opposed to the conception of MacGillavry (cf. following abstr.). II. *Ibid* 583-4.—H. claims that the ambiguous conclusions of MacGillavry regarding the mass-action relation between Cu and cellulose in Schweitzer's reagent rests upon the wrong assumption that the reaction velocity between the Cu base and a glucose residue in a large cellulose mol. is independent of the amt. of Cu. F. A. SIMMONDS

**The molecular weight of cellulose.** D. MACGILLAVRY. *Rec. trav. chim.* **48**, 492-3(1929); cf. preceding abstr.—The behavior of the rotatory power of cellulose in Schweitzer's reagent can be explained by the assumption of equiv. glucose residues, without being obliged to consider the size of the mol. Conversely, if the assumption is correct the size of the mol. cannot be detd. from this behavior. F. A. SIMMONDS

**Drying of cellulose by the Fidalgo system.** GUNNAR BROLIN. *Svensk Pappers-Tid.* **32**, 197-9(1929).—The app. is described. W. SEGERBLOM

**Polyoxymethylene a model of cellulose.** H. STAUDINGER. *Oesterr. Chem.-Ztg* **32**, 98-9(1929).—A homologous series of polymers (polyoxymethylenes and derivs.) was built up through polymerization of formaldehyde. Means of detg. the cryst. structure, phys. properties and chem. constitution were outlined. R. Signer obtained a homolog showing a fiber diagram similar to that of cellulose. Conclusion: The secondary mol. structure of cellulose is no longer tenable. The structure of cellulose should be studied through synthesis of carbohydrate polymers. F. A. SIMMONDS

**Proposed tentative specifications and tests for soluble nitrocellulose.** ANON. *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 71s, 10 pp.—The properties and tests included are appearance, ash, nitrogen, stability, consistency (viscosity), soly. and appearance of the soln., film test and toluene diln. test. Drawings of the app. for the nitrogen and stability detns. are shown. F. A. SIMMONDS

**Study on celluloseglycolic acid.** ICHIRO SAKURADA. *Z. angew. Chem.* **42**, 640-3(1929).—See *C. A.* **22**, 1849. F. A. SIMMONDS

**Artificial silk cellulose.** H. E. WAHLBERG. *Svensk Pappers-Tid.* **32**, 236-8(1929).—Descriptive résumé. W. SEGERBLOM

**Steam and warm water distribution in sulfate pulp plants.** TORBJORN MOLIN AND JONAS BOJJA. *Svensk Pappers-Tid.* **32**, 200-1, 240-1(1929); cf. *C. A.* **23**, 3089. M. questions B.'s previous statement concerning a yield of 50% oven-dry pulp in sulfate plants and recalcs. figures on the heat balance between the black liquor and the soda house. B. answers that a 50% yield has been obtained at the Iggesund sulfate plant and comments on the revised calcs. W. SEGERBLOM

**Contribution on the knowledge of the sulfite process.** I. The action of bisulfite liquor on various sugars. TSUNEYA MARUSAWA, DEN-ICHI NAITO AND JUN-ICHI UCHIDA. *Mem. Ryojun Coll. Eng.* **1**, 351-93(1929).—In aq. soln.,  $NaHSO_3$  combined at room temp. with glucose, mannose and xylose, but not levulose, to form loose readily dissoed. compds. and at 130° with each of the sugars in monomol. ratios to form at least 2 solid compds., "A" and "B," entirely different from those formed at room temp. The "A"-compd. which forms first is readily decompd., with increasing temp. and H-ion concn., into thiosulfate, sulfate and polythionates, the first of which catalyzes the decompn. of the  $SO_3$  ion. This tendency toward thiosulfate formation is greatest with glucose and least with levulose. If the H-ion concn. is sufficiently low, the cyclic

"B"-compd. is formed, probably by an intramol. rearrangement of the "A"-compd.

C. E. HRUBESKY

**Theoretical and experimental details on the preparation of sulfite pulp from pine wood.** O. ROUTALA AND J. SEVÓN. *Cellulosechemie* 10, 97-107(1929).—In seeking a practical means of removing resins from pine and other resinous woods R. and S. reviewed previous methods of extn (cf. Hågglund, *C. A.* 22, 4805) and present a new method of converting unextd. resinous woods into pulp using a mixt. of  $\text{NaHSO}_3$  and  $\text{MgHSO}_3$ . A series of cooks using ordinary  $\text{CaHSO}_3$  liquor (I) and  $\text{MgHSO}_3$  and  $\text{NaHSO}_3$  liquor (II) was made. General cooking conditions were: time 16-18 hrs. at  $140-5^\circ$  under 5-7 atm. pressure. Yields: (I) pulp 46.1 and 50.5% (24-33.7% unconverted), (II) 45.3, 44.7 and 45.2% (2.4, 2.7 and 1.1% unconverted). Conclusions: The replacement of Ca by Mg and Na in the sulfite liquor permits a satisfactory conversion of well-seasoned wood of high resin content and irregular compn. The resulting pulp was dark and rich in resin. The addn. of weak acids such as  $\text{AcOH}$  and phosphoric acid or their alkali salts permits a shorter cook period (12 hrs.) and gives good yields (43.4-48.7%) and higher-quality pulp. The addn. of the salt or acid causes the resin to dissolve more readily and prevents the deposition of  $\text{CaSO}_3$  in wood pores. Resins may be partially (20%) removed from pulp by shaking with small quantities of  $\text{NaOH}$  liquor.  $\text{HNO}_3$  disintegration of pine wood yields good pulp but is not practical on a large scale. Application of these results to the control of com. sulfite cooks is discussed.

C. W. SONDERN

**The catalytic action of selenium on calcium bisulfite pulping solution.** N. F. YERMOLENKO. *Chem.-Zig.* 53, 343-4(1929).—All pyrites used for the prepn. of sulfite liquor contain a varying amt. of Se which collects in the liquor. The catalytic effect of Se in converting  $\text{H}_2\text{SO}_3$  to  $\text{H}_2\text{SO}_4$  is about 500 times that of free S. When wood chips are subjected in an autoclave to the action of sulfite liquor contg. varying amts. of Se, there is an increased darkening of the liquor, charring of the wood and pptn. of  $\text{CaSO}_4$ , but a decreased formation of  $\text{CaSO}_3$  as the temp., pressure and concn. of Se are increased. 1.4 mg. Se per l. of liquor causes an intense darkening of the soln. and charring of the wood when kept in the autoclave 10 hrs. at a temp. of  $125-130^\circ$  and a pressure of 3-4 atm.

C. E. HRUBESKY

**A new acid-resisting cement for sulfite digesters.** H. KREUGERS. *Svensk Pappers-Tid.* 32, 239-40(1929).—An unusually high chimney to carry off strongly acid gases occasioned the prepn. of a new acid-resisting cement (compn. not given) with lime content claimed to be reduced about half that in similar cements. The new cement after 20 days was only slightly affected by 5-20%  $\text{H}_2\text{SO}_4$ ; with 50%  $\text{H}_2\text{SO}_4$  it was rapidly attacked and disintegrated. Ordinary cement disintegrated after 20 days with 5%  $\text{H}_2\text{SO}_4$ ; 10-50% needed only 10 days.

W. SEGERBLOM

**Critical study of methods of measuring the bulk of paper.** F. T. CARSON. *Bur. Standards J. Research* 2, 1039-56(1929).—A standard method is proposed for measuring bulk which permits either the measurement of a pack of paper 0.1 inch or more in thickness with a thickness gage of standard type, or the measurement of a 1-inch pack under a pressure of 5 lb./sq. in. by means of a pressure bulker. It is recommended that the results be expressed as (a) bulking thickness, or the thickness in hundredths of an inch of a 100-sheet pack; and (b) specific bulk, or the ratio of bulking thickness to the standard ream wt. of the paper measured.

F. A. SIMMONDS

**Automatic control developed to maintain uniform density of suspensions.** ANON. *Chem. Met. Eng.* 36, 362-3(1929).—A Bradley-Osbourn viscosity control was put ahead of a Jordan in a kraft paper mill. An even power load, uniform Jordan operation and a smooth even stock on the paper machine resulted. A complete description of the machine and set-up are given.

F. A. SIMMONDS

**Experimental production of roofing felts.** MERLE B. SHAW, GEORGE W. BICKING AND O. G. STRIETER. *Bur. Standards J. Research* 2, 1001-16(1929).—The effects of substituting low-grade materials for considerable amts. of the common felt-making materials used in the production of roofing felts were favorable toward substitution. The materials used were No. 2 roofing rags, old jute and manila bagging, old newspapers and finely ground wood saw-dust. The phys. properties of exptl felts are tabularly compared with those of commercial felts.

F. A. SIMMONDS

**Treatment of paper-mill wastes (WOLMAN) 14.** Dehydration products of sorbitol [for gelatinizing cellulose esters or ethers] (Brit. pat. 301,655) 13. Neutralizing  $\text{H}_2\text{S}$  [in atmosphere of artificial silk factories] (Fr. pat. 656,801) 13. Recovery of volatile solvents [in production of artificial silk] (Brit. pat. 302,297) 13.

**The Manufacture of Pulp and Paper, Vol. V.** 2nd ed. Edited by J. N. STEPHENSON. New York: McGraw-Hill Book Co., Inc. 732 pp. \$6. Reviewed in *Chem. Met. Eng.* 36, 431(1929).

**Cellulose acetates.** I. G. FARBENIND. A.-G. Brit. 301,755, Dec. 2, 1927. In the production of acetone-sol. cellulose acetates, there is used as catalyst  $\text{ZnCl}_2$  together with free  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$ , or a substance yielding  $\text{HCl}$ , preferably in the proportion of 6.0:4.0:0.5. The acetylation product may be hydrolyzed.

**Ethers of cellulose and starch.** I. G. FARBENIND. A.-G. Brit. 302,191, Aug. 9, 1927. Materials such as cotton, wood pulp or starch are treated with alkali as by soaking in  $\text{NaOH}$  soln. and then treated with vaporous alkylating agents such as  $\text{MeCl}$  or  $\text{EtCl}$ . The ether obtained from sulfite cellulose may be used for making *artificial fibers or lacquers*, and the methylstarch obtained may serve as an *adhesive for paper or cardboard*.

**Carbohydrate derivatives.** I. G. FARBENIND. A.-G. Fr. 656,861, June 30, 1928. In alkylating, aralkylating or arylating carbohydrates such as cellulose, or starch, the reaction is carried out under vacuum, a gas such as  $\text{CO}_2$  which is afterward absorbed by the  $\text{NaOH}$  used being passed through the material.

**Sulfonated carbohydrates.** WILHELM TRAUBE. Fr. 657,204, July 10, 1928. Cellulose, starch or the like is treated with  $\text{SO}_3$  in soln. in  $\text{H}_2\text{SO}_4$  or  $\text{CS}_2$  or dild. with air or other gas for the production of sulfonated derivs. which may be used as *protective colloids* or as *intermediates for the production of acetyl- or nitro-cellulose*.

**Films, threads, etc., from ethylcellulose or similar materials.** I. G. FARBENIND. A.-G. Brit. 302,667, Dec. 19, 1927. In forming films, threads or the like from solns. contg. volatile solvents such as  $\text{CS}_2$ -ether, which dissolve gases, evapn. of the solvent during working up of the soln. is effected, during at least the early part of the process, at a low temp. (suitably  $10^\circ$  to  $-20^\circ$ ) to prevent the formation of an impervious skin and to facilitate escape of dissolved gas at a later stage of the process.

**Artificial films, fibers, etc.** I. G. FARBENIND. A.-G. Fr. 657,522, July 16, 1928. Films, fibers, etc., are prepd. clear and free of bubbles from solns. of cellulosic derivs. contg. gases, with easily volatile solvents which show a high dissolving power for the gases, by evapg. the solns. at the start at low temps., *e. g.*,  $+10^\circ$  to  $-20^\circ$  or below, and afterward evapg. at higher temps. Examples are given.

**Ammoniacal copper-cellulose solutions for artificial-silk manufacture.** K. HESS and C. TROGUS. Brit. 301,752, Dec. 3, 1927. The cellulose used is pretreated with ammoniacal  $\text{Cu}$  solns. to which caustic alkali has been added to effect such absorption of  $\text{Cu}$  that the cellulose will dissolve in very dil. ammoniacal  $\text{Cu}$  solns. or in  $\text{NH}_3$  solns. or even in water.

**"Viscose silk."** H. KINDERMANN. Brit. 301,811, Aug. 6, 1927. Coagulation of filaments is effected in 2 baths, the first comprising an acid and the second an aq. soln. of a compd. such as the chloride, nitrate or sulfate of  $\text{Cu}$ ,  $\text{Cd}$ ,  $\text{Sn}$ ,  $\text{Pb}$ ,  $\text{Hg}$ ,  $\text{Bi}$ ,  $\text{Sb}$ ,  $\text{Se}$  or  $\text{Te}$ . Such baths permit the treatment of unripe viscose. Use of an  $\text{As}$  compd. in the second bath is also mentioned.

**Artificial silk.** ARTIFIL-VEREDELUNGSGESELLSCHAFT M. B. H. Fr. 656,600, June 28, 1928. Threads of artificial silk are strengthened by passing them through a paste of fatty soap, glycerol and potato starch or albumin or gum.

**Artificial silk.** I. G. FARBENIND. A.-G. Brit. 301,563, Sept. 6, 1927. The process described in Brit. 280,628 (*C. A.* 22, 3300) for the stretch-spinning of ammoniacal- $\text{Cu}$  cellulose solns. at low temp. such as  $20-30^\circ$  or lower is modified by increasing the length of the vertical column of water used as coagulant (preferably to 50-80 cm.). Solns. prepd. from cotton as well as those prepd. from wood pulp, straw or grasses may be used.

**Creped artificial silk yarns.** Soc. INOXI. Brit. 302,340, Dec. 16, 1927. The yarns before twisting are at least partially dehydrated by heat and are then treated with a soln. of  $\text{Al}$  acetate or other suitable inorg. salt soln. in aq. solns. of acids which prevent appreciable rehydration before the twisting, which then ensues.

**Artificial silk from ammoniacal copper cellulose solutions.** J. P. BEMBERG A.-G. Brit. 302,890, Dec. 22, 1927. By the process described in Brit. 299,038 (*C. A.* 23, 3099) an artificial yarn is produced consisting of continuous practically endless individual filaments of 1.5 deniers or lower. The yarn has a tear resistance of more than 220 gr. per 100 deniers in the dry condition and more than 140 gr. when wet.

**Apparatus for spinning artificial silk.** J. P. BEMBERG A.-G. Brit. 302,846, Dec. 19, 1927. Structural features.

**Luminous silk.** ÉDOUARD M. SANDOZ. Fr. 656,997, July 4, 1928. Phosphorescent salts are incorporated in artificial silk during manuf.

**Artificial wool.** JACQUES DELPECH. Fr. 656,743, Nov. 14, 1927. An artificial wool contg. about 6% of S and of good heat-insulating properties is obtained by spinning viscose solns. without desulfurizing, and with the addn. of sol. polysulfides to the viscose soln.

**Paper manufacture.** GEORGES A. PAULIN, MAXIMILIEN RYNDZUNSKY and EUGÈNE TRINQUESSE. Ger. 477,539, Nov. 1, 1922. Pulp is made from vegetable matter by steeping in a bath of alk. agglutinant, casein and alkali resinate.

**Cellulose pulp for paper manufacture.** JOAQUIN J. DE LA ROZA, SR. (to Bagasse Products Corp.). U. S. 1,721,376, July 16. In producing pulp for the manuf. of snow-white paper of great strength, cellulose-contg. material such as wood, corn stalks or bagasse is treated in a hot aq. soln. contg. free S and is subsequently treated in a hot dil. alk. soln. (both treatments being at 160-73°) and then refined and washed.

**Apparatus for beating paper pulp.** J. WHITE, D. H. THOMSON and H. MILNE. Brit. 301,648, Dec. 7, 1927. Structural features.

**Steam-heated drying cylinders for paper-making apparatus.** A. D. HARRISON. Brit. 302,116, May 8, 1928. Structural features.

**Light-weight paper.** R. MCGILL. Brit. 301,682, March 6, 1928. A jelly-like mixt. formed of starch, glue, Na silicate and water (with or without precipitants, preservatives or the like) is mixed with pulp in a beater before addn. of size and of alum for fixing. Production of fluff in the manuf. of "antiques" for light-weight books is thus prevented. Various specified cellulosic pulps may be used with similar compns.

**Finishing paper and paper boards.** GEORGE F. BLOMBERG. U. S. 1,720,716, July 16. A liquid finishing compn. is used comprising rubber latex, colloidal clay and other sizing or surfacing materials such as casein, talc and blanc fixe.

**Waterproof paper and pasteboard.** I. G. FARBERNIND. A.-G. Brit. 301,807, Dec. 5, 1927. The cellulose derivs. of higher aliphatic acids mentioned in Brit. 289,063 (C. A. 23, 703) are mixed with paper pulp at any stage of its manuf. before it reaches the paper machine.

**Impregnated corrugated packing paper, etc.** A. KUPPER. Brit. 302,367, Dec. 15, 1927. The material is impregnated or coated with paraffin, stearin, beeswax, lacquers or rubber.

**Purifying oils.** SOC. MEUSIENNE DE PRODUITS CHIM. Fr. 656,728, June 29, 1928. Resinous oils recovered in the manuf. of paper are made available for soap manuf. by mixing with H<sub>2</sub>SO<sub>4</sub> and passing superheated steam through for 3-4 hrs., decanting and drying, and hydrogenating with H and a Ni or other catalyst.

## 24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

**A gas explosion in a rock-dusted mine.** G. S. McCAA. Bur. Mines, *Circ.* 6144, 5 pp.(1929).—The explosion occurred at a place in the mine where the fall of the coal deposit had been pushed back 38 ft. from the rock dusting and at a time when the rock-dusting machine and a car of rock dust was being pushed to the spot by an elec. locomotive. Evidently gas in considerable concn. accumulated at the high point and the mixt. was ignited possibly by a stray elec. arc. The explosion extended but little beyond the gas-filled area, and did not extend through the rock-dusted mine.

CHARLES E. MUNROE

**Sampling dust in rock-dusted mines.** C. W. OWINGS. Bur. Mines, *Circ.* 6129, 8 pp.(1929).—The methods advocated for sampling are described in detail, with examples from practice. It is recommended in the interest of safety that a set of samples be taken throughout the mine at least once each month.

CHARLES E. MUNROE

**Hazards in the use of delay-action detonators in coal mines.** D. HARRINGTON and S. P. HOWELL. Bur. Mines *Circ.* 6147, 2 pp.(1929).—In using delay-action detonators gas or dust may be released by the cut shot to form dangerous explosive atms. in the coal mine, and the atms. may be exploded with serious results by the dependent shots fired by the delay-action detonators.

CHARLES E. MUNROE

**A method of studying factors influencing the rate of burning or pressure development of black blasting powder.** A. B. COATES and J. E. CRAWSHAW. Bur. Mines, *Repts. of Investigations*, No. 2940, 9 pp.(1929).—The weighed charge of explosive was fired in the Bichel pressure gage in the customary manner except that the revolving

drum on which the time-pressure record is taken was run at a reduced speed, that speed of the drum was measured by a belt-driven tachometer, and that an induction coil in series with the elec. squib or electric detonator was introduced to mark on the time-pressure record the instant at which the squib or detonator was fired.

CHARLES E. MUNROE

**Inflammability of mixed gases.** G. W. JONES. *Bur. Mines, Tech. Paper* 450, 38 pp. (1929).—Results are given of expts. on mixts. of H, CH<sub>4</sub>, and CO with H and CO<sub>2</sub> in varying proportions. Data were obtained on the extinctive action of N and CO<sub>2</sub> on each of the 3 others from which curves were drawn and tables compiled whereby the inflammable limits of mixts. of each of the combustible with the inert gases can be obtained. By use of these data and the application of Le Chatelier's law it is possible to calc. the limits of inflammability in any mixt. of these gases. From the data one may also ascertain the O content below which the atm. must be maintained to render it non-inflammable. This is of special importance in safety work.

C. E. M.

**Inflammability of mixtures of ethyl alcohol, benzene, furfural and acetone.** G. W. JONES AND J. R. KLINK. *Ind. Eng. Chem.* 21, 791-3 (1929).—The following lower inflammable limits were detd. for solvents mixed with air at 125°: EtOH (d. 0.817, 5% H<sub>2</sub>O, b. 76-80°) 3.85%; PhH (b. 78-82°, d. 0.882) 1.53%; 2-furaldehyde (b. 161°, d. 1.159) 2.1%; AcMe (c. p., b. 55-7°) 2.92%; AcMe (com.) 3.18%. Mixts. of EtOH with PhH, furaldehyde and with AcMe were detd.; in all cases agreement within 0.24% was obtained with values calcd. from Le Chatelier's law (C. A. 22, 3976).

A. S. CARTER

**Determination of the compressive force of explosives.** K. F. MEYER. *Z. ges. Schiess-Sprengstoffw.* 24, 6-10 (1929).—The detn. of the compressive force of an explosive is of limited value in judging the practical value of the explosive. Valuable conclusions can be drawn from this test, however, as to the relative brisance of similar explosives. Different types of explosives vary as to their initial velocity of detonation, a factor of importance in the test. The method might be improved by providing strong confinement for the explosive. Both the method of Kast (with Cu cylinders) and that of Hess (with Pb cylinders) give varying results depending on the position of the detonator in the charge. The max. compression is obtained when the detonator is at the end of the charge opposite the cylinder. In practice, therefore, the detonator should be nearest the opening of the drill-hole.

C. G. STORM

**Spontaneous combustion in North Staffordshire—record of analyses of air samples taken during the combating of a gobfire.** T. DAVID JONES. *Colliery Guardian* 138, 2395-2400 (1929).—J. points out the value of air analyses in a coal mine to det. the progress made in combating a fire in one of the seams. In using the combustion period both the CO<sub>2</sub>/O<sub>2</sub> ratio and CO/O<sub>2</sub> ratio are high. Also in *Iron Coal Trades Rev.* 118, 902-3 (1929).

L. C. MILLER

**Measurement of explosive pressures of pure acetylene and acetylene saturated with water and acetone vapors.** W. RIMARSKI. *Autogene Metallbearbeitung* 22, No. 10, 134-40; *Acetylen in Wiss. u. Ind.* 32, No. 5, 73-7 (1929).—Explosive pressure of pure C<sub>2</sub>H<sub>2</sub> up to 9 kg. per sq. m. initial pressure is about 11 times the initial pressure. Water and acetone vapor reduce explosive pressure, but not to any great extent.

E. I. S.

**Temperatures of explosive decomposition of acetylene in relation to pressure and velocity of flow.** W. RIMARSKI. *Autogene Metallbearbeitung* 22, No. 10, 130-4; *Acetylen in Wiss. u. Ind.* 32, No. 5, 69-73 (1929).—Below 500° and at superpressures of 3 kg per sq. cm., explosive decompn. takes place. The pressure required to bring acetylene to explosive decompn. under adiabatic compression is about 170 kg. per sq. cm.

E. I. S.

**Colored-light compositions.** F. FEISTEL AND H. FISCHER. *Z. ges. Schiess-Sprengstoffw.* 24, 22-3 (1929).—A criticism of Henkel (C. A. 23, 2035). Objection is made to the use of NaNO<sub>3</sub> and NaClO<sub>3</sub> in pyrotechnic mixts. on account of hygroscopicity; to CuSO<sub>4</sub> because of danger of spontaneous decompn. The use of KClO<sub>4</sub> and S in any mixt. is condemned as dangerous even though brimstone, and not flowers of S, is prescribed.

C. G. STORM

Berthollet's detonating Ag and the formation of Ag mirrors (BAUM) 2.

**Explosive containing ammonium nitrate and hexamethylenetetramine.** JOSEPH A. WYLER (to Trojan Powder Co.). U. S. 1,720,459, July 9. An explosive which is readily detonated comprises NH<sub>4</sub>NO<sub>3</sub>, 76-96 and (CH<sub>2</sub>)<sub>6</sub>N<sub>4</sub>, 4 parts, with or without nitrostarch, NaNO<sub>3</sub>, ZnO, hydrocarbon oil, etc.

A filling material for containers for explosive gases. JOSEPH HAUSEN. Fr. 657,141, July 7, 1928. A filling material for containers for explosive gases is composed of mineral substances, having a size of grain of 0.5 mm. and below but excluding powd. material. The material may be used alone or mixed with larger grains of the same or a different material.

## 25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The one-bath, the two-bath and the acid methods of dyeing silk hosiery. W. C. DODSON. *Cotton* 93, 953-7, 983(1929).—Practical. Methods and formulas are given

RUBY K. WORNER

Dyeing wool with direct cotton dyes. A. E. PORAT-KOSHITZ. *Zhur. Prikladnoi Khim* 1, 11-20(1928).—Wool was dyed in a neutral bath with  $\text{NH}_4$  salts of Benzopurpurin 4B and Diamine Violet N which were prepd. from Na salts by pptg. free acids with  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , washing the ppt. with distd. water (dialysis was resorted to for the complete removal of sulfate and chlorine ions from Diamine Violet N as the dye is sol. in water), dissolving the ppt. in 30%  $\text{NH}_3$  soln. and evapg. the resulting soln. to dryness. The  $\text{NH}_4$  salt of Diamine Violet N thus prepd. contained 57% of Na salt as impurity, while the  $\text{NH}_4$  salt of Benzopurpurin 4B was practically pure. On boiling these salts with water they are hydrolyzed. Expts. are described from which it was found that some  $\text{NH}_3$  was retained by wool. When wool was boiled with aq.  $\text{NH}_3$  some  $\text{NH}_3$  was also adsorbed. When wool thus satd. with  $\text{NH}_3$  was boiled in distd. water or dyed in the manner described above, part of the  $\text{NH}_3$  was liberated. Cotton adsorbed  $\text{NH}_3$  salts (also Na salts) of these dyes as such. Conclusions: Unlike cotton, wool adsorbs only sulfo acids.

V. KALICHEVSKY

Tanning, dyeing and preservation of fishing nets. JAMES W. DURANT. *Dyer, Calico Printer* 61, 345(1929).—Deterioration of fishing nets is due to attack on the fiber by bacteria present in fish oil and by marine microorganisms, to general wear and tear and to oxidation of the fiber. To reduce tendering due to bacterial attack to a min., tanning is generally adopted. Methods are described.

RUBY K. WORNER

General specification for textile materials (methods of physical and chemical tests). ANON. Bur. Standards U. S. Government Master Specification No. 345a(1929).—(Supersedes F. S. B. No. 345 and B. S. Circular No. 293.)

E. H.

Electrical conduction in textiles. II. Alternating-current conduction in cotton and silk. E. J. MURPHY. *J. Phys. Chem.* 33, 200-15(1929); cf. *C. A.* 23, 1273.—The a. c. capacity of cotton increases rapidly with humidity. It undergoes a large reduction at high humidities when the amt. of electrolyte material present is decreased. The capacity of cotton at high humidities is considered due chiefly to the electrolytic polarization capacity of the water paths, forming a kind of electrolytic cell with the electrodes. The a. c. and d. c. conductivities are practically equal at humidities above 80 to 85%. At lower humidities, the a. c. cond. is higher than the d. c., the difference increasing with decreasing humidity; the d. c. cond. forms less than 1% of the a. c. cond. at humidities below about 25% for samples of normal electrolyte content and at humidities below about 45% for samples of low electrolyte content. Except at very low humidities, the electrolyte content of the textile affects the part of the a. c. cond. not due to the d. c., almost as strongly as the d. c. cond. With increasing humidity, the a. c. cond. increases with frequency less rapidly, the two becoming practically independent of each other at very high humidities. These relations apply to the a. c. and d. c. cond. of silk and other similarly behaving moisture-absorbing materials. In a c. conduction, a textile may be considered to act as an electrolytic cell in parallel with a dielectric, the water-paths forming the electrolyte. The a. c. capacity and cond. of the textile are due chiefly to the electrolytic cell component at high humidities, chiefly to the dielec. at very low humidities, and to a combination of both at intermediate humidities. III. Anomalous properties of conduction in textiles. *Ibid* 509-32.—The insulation resistance of cotton is a decreasing function of the applied voltage under all conditions. The ratio of the resistance at 40 v. to that at 400 v. appears to be approx. const. over the whole range of humidity, although the resistances themselves varied by a factor greater than  $10^8$ . The difference between the resistance at 40 v. and that at 400 v. is less the greater the electrode sepn. and the smaller the amt. of electrolytic material in the samples. For voltages greater than about 40, consideration of the ions adsorbed by the cellulose-water interface in the aq. conducting paths in cotton may largely explain the decrease of resistance with increasing voltage; probably in con-

sequence of a modified Wien effect, these ions may contribute more to the cond. the higher the applied voltage. The results of this investigation do not appear to support Evershed's interpretation of the "Evershed effect." The residual e. m. f. in cotton after the removal of an external e. m. f. was measured at several humidities, and was found to vary considerably with humidity. At humidities lower than about 25% the residual e. m. f. is a function of the applied voltage, but at high humidities, the observed values do not exceed the order of magnitude of decompn. potentials and over-voltages. The passage of a current through a textile tends to increase its resistance, the rate of change being rapid above 70-80% humidity but slow between 20 and 70% for cotton. The current produces a non-uniform distribution of resistance in the textile which may remain for several hrs. after the removal of the applied voltage. The distribution depends on the nature of the electrode material; for brass electrodes the resistance concentrates in the anode section, while for platinum electrodes, it concentrates in the middle of the thread. The anomalous properties of conduction in textiles at humidities above 20-30% can be explained in terms of electrolytic cells whose properties are somewhat modified by the distribution of the electrolyte in the solid dielectric. This conclusion is in accord with the conception of conduction in textiles previously proposed with regard to d. c. resistivity and a. c. capacity and cond. R. K. W.

**Adsorption of vapors by animal and vegetable fibers.** E. V. ALEKSEEVSKII, *Zhur. Prikladnoi Khim.* 1, 184-9(1928).— $\text{CCl}_3\text{NO}_2$  is best adsorbed by dyed new wool and dyed used silk while linen is the poorest adsorbent. It does not affect the fiber strength.  $\text{AsCl}_3$  is best adsorbed by wool, hairs and rubber. Paper is the poorest adsorbent, but disintegrates quickly, while the strength of wool fibers is not affected. Most of the adsorbents darken on exposures because of deposition of As.  $(\text{CH}_3)_2\text{SO}_4$  is slowly adsorbed by wool and quickly by cotton, but cotton and silk retain it tenaciously while wool loses it quickly through ventilation. It does not affect the fiber strength.  $\text{PhCH}_2\text{Cl}$  is adsorbed more quickly by animal than by vegetable fibers. Its adsorption is increased by moisture. Ventilation is not effective for its removal.  $\text{AcCH}_2\text{Br}$  is better adsorbed by animal than by vegetable fibers. Moisture also favors its adsorption. Strength and color of fabrics are affected to a considerable extent. V. K.

**Cloth finishing processes in relation to tensile strength.** ALEXANDER YEWDALL, *Wool Record* 35, 1169-71, 1237-9, 1309-11(1929).—A study of the effect of each step in the finishing process on the tensile strength of the fabric shows that the strength gradually decreases during each successive stage unless counteracted by some factor which increases the density of the fabric. Such processes as scouring, crabbing, blowing and boiling affect the fiber principally, whereas cutting and raising affect chiefly the thread structure. Milling increases the strength of the fabric on account of the larger no. of threads and picks in the same area and the support given by the fiber entanglement, although the fiber itself is weakened in the process. The effect was also studied of 4 different styles of finish, Melton, Clear-cut, Moss and Dress-face, on the tensile strength of the same basic structure. These arranged themselves in the order named, the Melton style giving the strongest fabric. RUBY K. WORNER

**Coupling arylsulfonanilides with diazo compounds (BATTEGAY, SCHNEIDER) 10.** Synthesis of substantive dyes derived from dicinnamylmethane (LAMPE) 10. Products for use in (dyeing) (Brit. pat. 302,666) 29. Recovery of volatile solvents (in cleaning fabrics) (Brit. pat. 302,297) 13. Fireproofing (of cloth) (Fr. pat. 656,693) 18. Reducing organic compounds (as in production of a leuco derivative from indigo) (U. S. pat. 1,721,319) 10. Apparatus for clarifying used dry-cleaning liquids (U. S. pat. 1,720,185) 1. Filter for "dry cleaning" liquids (U. S. pat. 1,720,384) 1.

ALLEN, NELLIE B.: **Cotton and Other Useful Fibers.** Boston and New York: Ginn and Co. 368 pp.

**Dye.** BRITISH DYESTUFFS CORP., LTD., WM. H. PERKIN and ALEXANDER W. RYFE. Ger. 478,280, Aug. 21, 1925. See Brit. 238,717 (C. A. 20, 2078).

**Dyes.** L. J. HOOLEY, J. THOMAS and SCOTTISH DYES, LTD. Brit. 301,769, June

1, 1927. Anthraquinoneacridinesulfonic acids dyeing wool bright bluish red shades are obtained by heating  $\alpha$ -arylaminoanthraquinones and their derivs. (other than those contg. a carboxylic acid group or an amino group in *o*-position to the arylamino group) with  $\text{H}_2\text{SO}_4$  of over 90% strength or oleum, at  $130^\circ$  or higher (suitably  $160$ – $70^\circ$ ).

**Dyes.** J. R. GEIGY SOC. ANON. Brit. 301,726, Dec. 3, 1927. Diazo dyes sol. in oil or fat are obtained by coupling, with unsulfonated components, tetrazotized diamines of the type  $\text{NH}_2\text{RCH}_2\text{R}'\text{NH}_2$  or  $\text{NH}_2\text{RCHR}'\text{R}'\text{NH}_2$  in which R and R' are substituted or unsubstituted aryl residues. Several examples are given.

**Dyes.** I. G. FARBENIND. A.-G. Brit. 302,928, Dec. 23, 1927. Acid wool dyes are made by reaction of a 4-halo-1-aminoanthraquinone-2-sulfonic acid with a monoacyl compd. of the *m*-phenylenediamine series contg. an alkyl, aralkyl or hydroaromatic residue in the acylamino group, e. g., by the reaction of Na 1-amino-4-bromoanthraquinone-2-sulfonate with *m*-aminomethylacetanilide by heating in the presence of  $\text{NaHCl}_2$  and  $\text{CuSO}_4$  soln.

**Dyes.** I. G. FARBENIND. A.-G. (Ottmar Wahl, inventor). Ger. 477,634, May 11, 1926. Triphenylmethane dyes capable of an after-chroming are prepd. by condensing 2 mols. of an aromatic *o*-hydroxycarboxylic acid with 1 mol. 4-benzylamino-3-sulfobenzaldehyde and oxidizing the leuco acid. Cresotic acid is mentioned in the example and the chroming of the oxidized leuco acid formed gives a fast violet color to wool.

**Dyes.** I. G. FARBENIND. A.-G. (Richard Herz and Wilhelm Hechtenberg, inventors). Ger. 477,697, Feb. 13, 1927. A fast blue S dye is prepd. by sulfurizing the quinone vat dye obtained by the condensation of the arylamino derivs. of *o*-aminoarylmecaptan of the general formula  $2,5\text{-H}_2\text{N}(\text{RR}'\text{N})\text{arylSH}$ , ( $\text{R}' = \text{aryl}$  and  $\text{R} = \text{H}$ , alkyl or aralkyl) with arylquinone or derivs., as described in 445,270.

**Dyes.** I. G. FARBENIND. A.-G. (Erwin Kramer, Ludwig Zeh and Bernhard Bollweg, inventors). Ger. 477,698, Jul. 1, 1927. A S dye is prepd. by heating binaphthylene dioxide with S to  $240$ – $280^\circ$ .

**Dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 656,886, July 2, 1928. Dyes giving rich violet shades are prepd. by mixing isoviolanthrone with halogenated isoviolanthrone such as dichloroisoviolanthrone either mech. or by oxidation of mixts. of the corresponding leuco derivs. either in substance or on the fiber.

**Dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 657,272, July 11, 1928. Chromed azo dyes are prepd. by treating azo dyes capable of being chromed with hydrated oxides of Cr in the presence of alk. reducing agents such as alkali sulfides or  $(\text{NH}_4)_2\text{S}$  or alkalies in combination with reducing agents such as glucose, cane sugar or the sol. disintegration products of starch or cellulose. The reaction may be carried out in an open or a closed vessel, with or without the addn. of colloidal or protecting substances or org. or inorg. salts.

**Dyes.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Fr. 656,691, May 29, 1928. Azo dyes are produced on wool, silk, leather, etc., by impregnating in the presence of  $\text{CH}_2\text{O}$  with coupling components contg. one or more  $\text{SO}_2\text{NH}$  or  $\text{SO}_2\text{NH}_2$  groups and developing with a suitable diazo compd. Thus, a yellow dye is obtained on wool from 1-(2'-methyl-5-sulfamido)-phenyl-3-methyl-5-pyrazolone and 2-chloroaniline. Several examples are given.

**Preserving dyes in a state of fine subdivision.** FELIX RISSE and ERICH FISCHER (to Grasselli Dyestuff Corp.). U. S. 1,719,944, July 9. An alkylcellulose such as methylcellulose is incorporated with insol. or difficultly sol. dyes at the time of their production or shortly thereafter. Examples are given.

**Azo dyes.** I. G. FARBENIND. A.-G. Brit. 302,173, Dec. 10, 1927. Azo dyes are made by diazotizing a 4-aminonaphthalimide deriv. in which the imide H may be substituted by alkyl, aryl or aralkyl (which derivs. may be substituted or not) and coupling with a 2,3-hydroxynaphthoic acid arylide in substance or on the fiber. Examples are given which produce bluish claret, blue-bordeaux, violet-brown, claret-red, violet and chocolate-brown dyeings.

**Azo dyes.** I. G. FARBENIND. A.-G. Brit. 302,251, Dec. 12, 1927. Azo dyes, insol. in water, are produced in substance, on a substratum or on the fiber by coupling with an arylide of 2,3-hydroxynaphthoic acid a diazotized dihalo-2-anisidine in which one halogen is in *p*-position to the methoxy group. The products are orange to claret-red dyes of good fastness to light and are fast to steaming without addn. of chromate so that they are especially suitable for use in printing processes. Several examples are given.

**Azo dyes.** I. G. FARBENIND. A.-G. Brit. 302,599, Dec. 17, 1927; Fr. 657,529, July 16, 1928. Azo dyes, insol. in water and of good fastness to light, are produced,

in substance or on the fiber, by coupling with arylides of 2,3-hydroxynaphthoic acid diazotized dihalo-2-aminotoluenes having one halogen in *p*-position to the  $\text{CH}_3$  group and having at least one halogen other than Cl. Several examples are given of dyes dyeing bluish red shades. Brit. 302,600 describes dyes giving generally various red shades formed by coupling diazotized 2,5-dihalogen-2-aminotoluenes with arylides of 2,3-hydroxynaphthoic acid. Brit. 302,601 relates to similar dyes formed by coupling diazotized 3,6- or 5,6-dihalogen-2-aminotoluenes with arylides of 2,3-hydroxynaphthoic acid. Various examples are given.

**Azo dyes.** I. G. FARBENIND. A.-G. Fr. 656,575, June 27, 1928. Insol. azo dyes are prep'd. by combining the diazo comp'd. obtained from 3,6-diamino-7-methoxy-10-(2'-methoxyphenyl)phenazonium chloride with the arylides of 2,3-hydroxynaphthoic acid, in substance or on the fiber. An example is given using 2,3-hydroxynaphthoyl *p*-phenetidine giving a deep black. A list of other arylides which may be used is given.

**Azo dyes.** I. G. FARBENIND. A.-G. Fr. 657,115, July 6, 1928. Azo dyes are prep'd. by coupling diaminodisazo comp'ds. obtained from benzidinesulfonic or -carboxylic acids or their derivs. with 2 mols. of middle components capable of being diazotized anew and coupling the diazo derivs. with 2 mols. of sulfonic acids of 2-amino-8-naphthol, their derivs. arylated in the  $\text{NH}_2$  group or their derivs. sulfonated or carboxylated in the aryl ring. In an example, benzidine-*m*-disulfonic acid is diazotized and coupled with an AcOH soln. of 1-naphthylamine-6-sulfonic acid. The disazo dye is isolated, diazotized and coupled with 2,8-aminonaphthol-3,6-disulfonic acid. The polyazo dye dyes silk in black to blue shades. A number of other components which may be used are mentioned.

**Azo dye.** I. G. FARBENIND. A.-G. (Winfried Hentrich and Rudolf Knoche, inventors). Ger. 477,912, Mar. 13, 1927. Diazo comp'ds. are allowed to react with components to which an arylhydroxy fatty acid residue is coupled by a N atom. Thus, the Na salt of the monoazo dye obtained from the acid coupling of 1 mol. 4-nitro-1-aminobenzene-2-sulfonic acid with 1 mol. 2-( $\omega$ -aminoethylamino)naphthalene-7-sulfonic acid, is coupled with the diazo comp'd. from 4-nitro-1-aminobenzene-2-sulfonic acid. The new dye colors wool in fast red-violet tones. Other examples are given.

**Production of azo dyes on the fiber.** I. G. FARBENIND. A.-G. (Erwin Hoffa and Carl Seib, inventors). Ger. 478,031, June 14, 1927. See Brit. 292,100 (C. A. 23, 1513).

**Polyazo dyes.** I. G. FARBENIND. A.-G. Fr. 656,948, July 3, 1928. Tris- and tetra-azo dyes are prep'd. by coupling monoaminodiaz or aminodisazo comp'ds. which may be obtained from any diazo or diazoazo comp'ds. or amino or thioamino ethers of the  $\text{C}_6\text{H}_6$  or  $\text{C}_{10}\text{H}_8$  series and coupling in position *p*- to the  $\text{NH}_2$  group with *N*-aminobenzoylaminobenzoylaminobenzoyl- or *N*-aminobenzoylaminobenzoyl-*peri*-aminonaphthols (one or more of the CONH linkages in these comp'ds. may be replaced by  $\text{NH.CO.NH}$ ) then diazotizing again and coupling with pyrazolones, derivs. of  $\beta$ -ketoaldehyde, methylketol or its homologs or substitution products, sulfazones, 1,3-dihydroxyquinoline, salicylic acid and their derivs. capable of coupling. Examples are given.

**Trisazo dyes.** I. G. FARBENIND. A.-G. (Hugo Schweitzer and Johann Huismann, inventors). Ger. 478,045, May 18, 1926. Addn. to 450,998. See Brit. 287,232 (C. A. 23, 525).

**Chromium compounds of azo dyes.** I. G. FARBENIND. A.-G. Brit. 302,709, Sept. 15, 1927. Monoazo dyes obtained by coupling a diazotized *o*-aminonaphthol mono-sulfonic acid with a 1-sulfo-phenyl-3-methyl-5-pyrazolone free from sulfamide and OH groups are converted into Cr comp'ds. (suitably by reaction with Cr formate). Examples are given of dyes which give various pink or red shades. Cf. C. A. 23, 4080.

**Chromium compounds of azo dyes.** SOC. ANON. POUR L'IND. CHIM. A. BAILE. Brit. 301,772, Aug. 4, 1927. The parent azo dye is treated with a Cr-yielding agent comprising an org. Cr salt or an inorg. Cr salt and an acid-binding substance, in the presence of a salt of an org. acid, or a free org. acid, or both, or a salt of an inorg. acid together with a free org. acid. Several examples are given.

**Vat dyes.** BRITISH DYE-STUFFS CORP., LTD. Fr. 656,648, June 29, 1928. New vat dyes are prep'd. by condensing with  $\text{NH}_2\text{OH}$  or its salts, in the presence or not of  $\text{FeSO}_4$ , the products obtained by alk. fusion of the homologs or sulfonated derivs. of benzanthrone such as the condensation of  $\text{NH}_2\text{OH}$  with the product of alk. fusion of (1) sulfonated chlorobenzanthrone, and (2) sulfonated methylbenzanthrone.

**Vat dyes.** I. G. FARBENIND. A.-G. (Paul Nawiasky and Julius Müller, inventors). Ger. 478,047, Oct. 6, 1926. The green vat dye prep'd. according to example 1 of Ger. 475,342 (C. A. 23, 3353) is treated with oxidizing agents, in substance or on the fiber.

whereby it is converted into a fast brown vat dye. Examples are given describing the oxidation in substance with  $\text{CrO}_3$  and on the fiber with  $\text{CaOCl}_2$ .

**Vat dyes.** I. G. FARBENIND. A.-G. (Albert Job, inventor). Ger. 477,510, Aug. 26, 1926. See U. S. 1,690,786 (C. A. 23, 526).

**Brown vat dyes.** I. G. FARBENIND. A.-G. Brit. 302,489, Dec. 5, 1927. Brown vat dyes are made by halogenating the product obtained by "mild oxidation" of the leuco compd. of the brown vat dye described in example 2 of Brit. 289,980 (C. A. 23, 980). Various examples are given.

**Dyes of the pyrazolanthrone-yellow series.** I. G. FARBENIND. A.-G. Brit. 302,772, Oct. 31, 1927. Pyrazolanthrone-yellow, or its substitution products such as have not more than one univalent substituent on the N, are condensed with an aldehyde such as benzaldehyde, paraformaldehyde or paraldehyde in the presence of a chloride of P, Al or Sb (preferably in a diluent) at 100–200°, to form yellow to gold-orange vat dyes.

**Dyes of the thioindigo series, etc.** I. G. FARBENIND. A.-G. Brit. 302,175, Dec. 8, 1927.  $\text{P}_2\text{O}_5$  applied to a powdered or porous carrier such as anhydrous silicic acid is used for ring closure of arylthioglycolic acids. Examples are given.

**Anthraquinone dye.** ROLAND G. ROGERS (to National Aniline & Chemical Co.). U. S. 1,721,318, July 16. In the production of a leuco compd. of a diaminodihydroxyanthraquinonemonosulfonic acid, a diaminodihydroxyanthraquinonedisulfonic acid is subjected to the action of Zn and  $\text{NaHSO}_3$ . Cf. C. A. 23, 716.

**Sulfurized dyes.** I. G. FARBENIND. A.-G. Fr. 656,897, July 2, 1928. Sulfurized dyes giving reddish brown shades are prep'd. by heating to a high temp.  $\beta$ -binaphthol with halides of S such as  $\text{S}_2\text{Cl}_2$ , with or without the addn. of S and indifferent solvents

**Sulfurized dyes.** I. G. FARBENIND. A.-G. Fr. 656,907, July 2, 1928. Sulfurized dyes are prep'd. by sulfurizing indophenols or their leuco compds. with polysulfides in a soln. of aromatic hydroxy derivs., partially or entirely hydrogenated, such as cyclohexanol, methylcyclohexanol, tetralol or decalol. Cf. C. A. 23, 3816.

**Dyes and intermediates.** I. G. FARBENIND. A.-G. Brit. 302,773, Oct. 31, 1927. Arylides of 2-arylmino-8-naphthol-6-carboxylic acids are formed from 2,6-naphthol-carboxylic acid by sulfonation, converting the sepd. 8-sulfonic acid (cf. Brit. 291,965; C. A. 23, 1139) into 8-hydroxy-2-naphthol-6-carboxylic acid by alkali fusion, heating this product with a primary arylamine and treating the 2-arylmino-8-naphthol-6-carboxylic acid thus obtained with an arylamine and a dehydrating agent as described in Brit. 13,237 (C. A. 8, 3864). By using these arylides with various diazo compds. (of which several examples are given), azo dyes are obtained which dye wool reddish to black shades, cotton olive to black, and are suitable for making lakes.

**Dyes and intermediates.** I. G. FARBENIND. A.-G. (Arthur Lüttringhaus, Paul Nawiasky and Arthur Krause, inventors). Ger. 478,492, Oct. 26, 1926. New products useful as vat dyes or as intermediates for dyes are prep'd. by treating anthrapyrimidone and its derivs. and substitution products with alk. reagents. An example is given in which anthrapyrimidone is treated with alc. KOH at 180°.

**Dye intermediates.** I. G. FARBENIND. A.-G. (Leopold Laska and Arthur Zitscher, inventors). Ger. 478,331, Oct. 6, 1925. Sulfo derivs. of hydroxyaryl carboxylic acid arylides, the sulfo group being in the arylide radical, are prep'd. by treating a mixt. of an hydroxyaryl carboxylic acid and an aminoaryl sulfonic acid with  $\text{PCl}_3$  in the presence of an indifferent base such as  $\text{PhNMe}_2$ . Thus, 2,3-hydroxynaphthoylemetanilic acid can be prep'd. from 2,3 hydroxynaphthoic acid and metanilic acid. Other examples are given.

**Naphthalene derivatives.** IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 657,176, July 9, 1928. Polychloronaphthalenesulfonic acids are prep'd. by sulfonating polychloronaphthalenes contg. 3 to 4.5 Cl atoms in the mol. The products have wetting out properties and are used for making aq. pastes or suspensions of dyes. The prepn. of pastes from Duranthrene golden orange Y, thioindigo, and 2,4-dinitrobenzeneazo- $\beta$ -naphthol with trichloronaphthalenesulfonate is described.

**Naphthalene derivatives.** I. G. FARBENIND. A.-G. Brit. 302,770, Oct. 28, 1927. 2,8-Dihydroxynaphthalene-6-carboxylic acid is made by fusing 2-naphthol-8-sulfo-6-carboxylic acid with caustic alkali. By its use as an intermediate together with aromatic o-hydroxydiazo compds. (of which several examples are given), mordant dyes are obtained which dye wool brownish tints turning to fast brown to black shades when after-chromed.

**Anthraquinone derivatives.** I. G. FARBENIND. A.-G. (Paul Tust, inventor). Ger. 478,046, Apr. 10, 1926. New products useful as vat dyes or as intermediates for dyes are prep'd. by condensing benzoylaminoanthraquinones contg. halogen in the ben-

zoyl nucleus with aminoanthraquinones or their derivs. or substitution products. The condensation proceeds with elimination of H halide from the  $\text{NH}_2$  group or groups of the aminoanthraquinone and the halogen in the benzoyl nucleus. The reaction is generally conducted at a raised temp. in a diluent medium in the presence of an acid binding agent such as NaOAc and of a catalyst such as Cu. Examples are described.

**Anthraquinone derivatives.** I. G. FARBENIND. A.-G. (Robert E. Schmidt and Robert Berliner, inventors). Ger. 478,048, Jan. 26, 1927. New N-contg. products of uncertain constitution, some of which are useful as *dyes* for acetate silk and as *intermediates* for *dyes*, are prep'd. by the action of  $\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$  on hydroxyanthraquinones. The reaction generally proceeds at a slightly raised temp. Examples are given describing the manuf. of products from quinizarin, purpurin and 1,4,8-trihydroxyanthraquinone. The product from 1,2,4,5,8-pentahydroxyanthraquinone is described also.

**$\omega$ -Aminoalkylaminonaphthalenecarboxylic acids.** I. G. FARBENIND. A.-G. and W. HENTRICH. Brit. 302,212, Sept. 12, 1927. These products, which are *dye intermediates*, are obtained by the reaction of an alkylenediamine and a sol. sulfite on a hydroxy- or an amino-naphthalenecarboxylic acid (other than one contg. the OH or NH group in *o*-position to the COOH group). Examples are given of the production of these intermediates and of *dyes* from them.

**4-Chloro-1-aminoanthraquinone-2-sulfonic acid.** I. G. FARBENIND. A.-G. Brit. 302,171, Dec. 8, 1927. This comp'd. (which may serve as a *dye intermediate*) is prep'd. by treating well-cooled 1-aminoanthraquinone-2-sulfonic acid in aq. soln. or suspension with Cl or a substance yielding Cl. A temp. below  $0^\circ$  is suitable for the reaction.

**Aminoaryl mercaptans.** I. G. FARBENIND. A.-G. Fr. 657,183, July 9, 1928. *o*-Aminoaryl mercaptans are prep'd. by heating 2-aminoarylthiazoles with alk. lvs. in the presence or not of org. solvents or diluents. The products are *intermediates* in *thioindigo dyes*. The process may be applied to 2-aminothiazoles in which the *p*-position to the N atom is substituted or blocked, which are prep'd. according to Fr. 620,799. The mercaptans react with  $\text{ClCH}_2\text{CO}_2\text{H}$  to form thioglycolic acids and their anhydrides.

**Dyeing processes.** RENÉ CLAVEL. Fr. 657,003, July 4, 1928. White or colored discharges are produced more easily upon materials made of, or contg. cellulose esters or ethers by a preliminary mordanting of the material with metallic salts capable of forming compds. with the dyestuffs. The salts of Sn, Zn, Al, Fe or Cr or mixts thereof are applied in the form of printing pastes in the presence of acids or acid salts, and the treated material is dyed and then discharge printed. Examples are given of the use of an Al salt, and of Zn phosphate.

**Dyeing with vat dyes.** I. G. FARBENIND. A.-G. (Julius Höpker, inventor). Ger. 478,032, May 7, 1927. See Brit. 290,177 (C. A. 23, 994).

**Dyeing textiles.** THE MANCHESTER OXIDE CO., LTD. Fr. 656,827, June 28, 1928. Carbonylferrocyanides of alkali or alk. earth metals are used in oxidizing processes in dyeing textiles. They may be used in chlorate decolorizing pastes instead of the usual prussiate.

**Dyeing cellulose esters and ethers.** I. G. FARBENIND. A.-G. Brit. 301,564, Sept. 6, 1927. Non-phototype dyeings are obtained by use of azo dyes produced by coupling diazotized aminomonosulfonic or aminomonocarboxylic acids or substitution products of such acids with  $\alpha,\gamma$ -diketohydrindene or its derivs. Examples are given for dyeing "acetate silk" yellow.

**Dyeing cellulose esters and ethers.** I. G. FARBENIND. A.-G. (Erich Fischer, inventor). Ger. 477,507, Sept. 18, 1925. Cellulose esters and ethers are dyed with primary disazo dyes contg. one sulfo group, at least one amino or substituted amino group, and one naphthalene nucleus. The dyes are prep'd. by coupling 2 mols. diazo comp'd. with 1 mol. of a mono- or a dihydroxy comp'd. of the benzene or naphthalene series capable of coupling twice. Thus, acetate silk is dyed with the dye sulfanilic acid  $\rightarrow$  phenol  $\leftarrow$  *p*-phenylenediamine. Other examples are given.

**Dyeing cellulose esters and ethers.** SOC. ANON. POUR L'IND. CHIM. À BAËLE. Ger. 478,476, Nov. 2, 1926. Fast green or blue shades are produced on cellulose esters and ethers by dyeing with indophenols of the formula  $\text{R}_1(\text{R}_2)\text{N}-\text{R}_3-\text{N}=\text{R}_4=\text{O}$ , where  $\text{R}_1$  and  $\text{R}_2$  may be H or an alkyl, aryl or aralkyl residue,  $\text{R}_3$  is an aryl residue which may be substituted, and  $\text{R}_4$  is an aryl residue substituted in the nucleus with at least 1 halogen atom. Such indophenols may be prep'd. by joint oxidation of a halogenated *p*-aminophenol and an aromatic amine having the *p*-position free, or by condensing a halogenated *p*-nitrosophenol with an aromatic amine having the *p*-position free, or by joint oxidation of a suitable *p*-diamine and a halogenated phenol having the *p*-position

free. A no. of initial materials are specified from which suitable indophenols can be prep'd. An example is given. Cf. C. A. 23, 1514.

**Dyeing cellulose derivatives.** HENRY DREYFUS. Fr. 656,931, June 28, 1928. Materials made of or contg. org. substitution derivs. of cellulose are dyed, printed or stenciled by oxidation of one or more amines on the material by means of a chloroamide. Examples are given. Cf. C. A. 23, 4083.

**Dyeing cellulose derivatives.** I. G. FARBENIND. A.-G. Fr. 656,995, July 4, 1928. In dyeing cellulose esters or ethers isocyclic bases such as hexahydroaniline, or its homologs or substitution products or their salts or their salts with acid dyes are added to the dye bath, whereby deeper shades are obtained than without them.

**Dyeing cellulose derivatives.** HENRY DREYFUS. Fr. 657,181, July 9, 1928. Materials made of or contg. cellulose derivs. are dyed or otherwise colored with compds. obtained by introducing one or more  $\beta$ -ketoacidyl groups into coloring matters contg. suitable  $\text{NH}_2$  groups. The coloring matters may be of the azo, nitrodiarylamine, nitrodiaryl, nitrodiarylmethane, or anthraquinone series and are usually unsulfonated. They may be prep'd. by heating the dyestuffs contg. one or more  $\text{NH}_2$  groups with an acylacetic ester either in excess or in the presence of a diluent such as naphtha,  $\text{PhCl}$ ,  $\text{C}_{10}\text{H}_8$ , and may contain addnl. groups, e. g., amino, hydroxy, alkoxy, halogen, carboxyl or mercapto groups. A list is given of suitable compds. and the shades obtained there-with and examples of dyeing with these compds. are also given.

**Dyeing "viscose silk."** I. G. FARBENIND. A.-G. Brit. 301,754, Dec. 2, 1927. Uniform dyeings are obtained by use of secondary disazo dyes comprising: (a) a diazo component free from nitro or salicylic groups, (b) any customary middle component, and (c) a substituted or unsubstituted naphthol or naphthylamine coupling in *o*-position to the OH or  $\text{NH}_2$  group (*N*-substituted 2-amino-8-naphthol-6-sulfonic acids being excepted). Examples are given of dyes producing various bluish shades.

**Dyeing loosely woven articles.** HERBERT E. GRIER (to R. H. Comey Brooklyn Co.). U. S. 1,720,595, July 9. Articles such as those of loosely woven paper which tend to become soft and to lose their shape when wet are treated with a soln. contg. Japan wax, Carnauba wax or other suitable wax dissolved in a solvent such as  $\text{C}_6\text{H}_6$  or xylene contg. also a dye. U. S. 1,720,596 specifies the use of similar solns. contg. also a resin such as gum dammar.

**Coloring cellulose derivatives.** CAMILLE DREYFUS. Fr. 656,466, June 26, 1928. See Brit. 293,022 (C. A. 23, 1514).

**Printing fabrics.** I. G. FARBENIND. A.-G. (to Durand et Huguenin Soc. anon.), Brit. 302,291, Dec. 13, 1927. Fast-colored discharges are obtained on dyeings which are destroyed by oxidizing agents by use of enolic esters of vat dyes; e. g., goods dyed with indigo or Gallomarine blue 2 GD are printed with pastes contg. the ester salts of 6,6'-diethoxythioindigo (for orange discharges), 4,4'-dimethyl-6,6'-dichlorothioindigo (for pink discharges), quinone-di-*p*-chloroanilide (for yellow discharges), or dimethoxy-dibenzanthrone (for green discharges), followed by drying, steaming, treating with waterglass soln. and washing. Various auxiliary ingredients for use in the printing pastes are specified.

**Printing fabrics with vat dyes.** E. I. DUPONT DE NEMOURS & Co. Brit. 302,252, June 8, 1927. A hydroxyalkylamine such as monoethanolamine, diethanolamine, triethanolamine, products obtained by the interaction of olefin oxides with  $\text{NH}_3$  or alkylammonias or methyl-di-( $\beta$ - $\gamma$ -dioxypentyl)amine is used as an assistant in printing fabrics with vat dyes.

**Apparatus for dyeing hanks and various loose materials.** J. SYKES & SONS, LTD. and E. P. SYKES. Brit. 302,486, Dec. 1, 1927. Structural features.

**Apparatus for dyeing and other treatments of artificial silk skeins.** JOHN BRAND-WOOD. U. S. 1,720,760, July 16. Structural features.

**Apparatus for treating lengths of fabric with dyeing, bleaching or washing liquids.** FARBREI WEIDMANN A.-G. Brit. 302,598, Dec. 17, 1927. Structural features.

**Apparatus for washing, dyeing or mixing operations.** E. FREUND. Brit. 302,316, Dec. 14, 1927. Structural features.

**Screw propeller for circulating liquor in dye vats.** E. CONSTANT and L. CONSTANT (trading as Soc. E. et L. Constant). Brit. 302,186, Dec. 10, 1927. Structural features.

**Dye stick of stainless steel.** C. CALLEBAUT and J. DE BLICQVY. Brit. 302,857, May 10, 1928. Structural features.

**Use of glycol ethers in dyeing liquids.** H. T. BÖHME A.-G. Brit. 301,824, Dec. 6, 1927. The degree of dispersion of colloidal dye solns. is reduced and the efficacy of the liquid enhanced by use of compds. such as ethylene glycol monomethyl ether.

**Textiles.** TOOTAL BROADHURST LEE CO., LTD. Fr. 657,348, Nov. 30, 1927. See Brit. 291,473 (C. A. 23, 1289).

**Artificial textiles.** GUSTAV BONWITT. Fr. 34,038, Sept. 8, 1927. Addn. to 640,644 (cf. C. A. 23, 982).

**Sizes for textile materials.** A. F. GALVIN. Brit. 302,358, Dec. 15, 1927. A size is prep'd. by melting in gasoline or the like Japan wax, carnauba wax or gum dammar or other benzine-sol. gum, tallow, stearin or paraffin, benzine soap or saponifiable oil or similar materials.

**Preparing cut fibers.** I. G. FARBENIND. A.-G. (applicant in U. S. M. F. Thomas). Fr. 657,352, Dec. 26, 1927. Cut fibers are treated in a bath to render them supple, brilliant and hygroscopic and in another bath to render them soft to the touch. The first bath may contain glycerol, an alkali, soft soap, oil soap, and glucose and the second AcOH, HCOOH or oil soap contg. traces of H<sub>2</sub>SO<sub>4</sub>.

**Improving fibrous materials.** OBERRHEINISCHE HANDELS-GES. Brit. 301,881, Dec. 7, 1927. Cotton, wool, artificial silk, etc., are curled and rendered more suitable for spinning or use as stuffing material by treatment with liquids such as water, or aq. solns. contg. soap, alkali, acid, oil, fatty acids or bleaching agents, and drying in the loose state.

**Retting flax fiber.** M. WADDELL and H. C. WATSON. Brit. 302,300, Sept. 14, 1927. See U. S. 1,708,812 (C. A. 23, 2582).

**Retting stem fibers.** C. E. BAIRE. Brit. 302,052, Dec. 14, 1927. A disintegrating liquor such as an ammoniacal or alk. carbonate soln. is used together with cholesterol or a material such as fish oil, egg yolk, egg oil, wool fat or cerebral substance; the treatment may be effected by boiling under pressure for 12 hrs.

**Mercerizing loose cotton fibers.** C. AHNERT. Brit. 301,591, Oct. 3, 1927. Unspun cotton is mercerized by impregnation at a high temp. with the usual lye and stretching by centrifugal force while exposed to the action of the lye. An app. is described which may comprise a drum lined with spongy rubber.

**Apparatus for cooling caustic liquids used in mangle tanks of mercerizing apparatus, etc.** S. S. HAMMERSLEY and J. A. BOLTON. Brit. 302,004, Oct. 12, 1927.

**Drying and bleaching fabrics.** M. M. KASANOF. Brit. 301,783, Sept. 5, 1927. Tubular fabrics are drawn over a hollow perforated stretching device through the perforations of which compressed air or bleaching agents may be passed. Various structural details are described.

**Bleaching process for textiles.** A. DE CARVALHO. Belg. 355,916, Dec. 31, 1928. O<sub>3</sub> is used, preferably in gaseous form.

**Apparatus for bleaching textiles with solutions liberating oxygen.** DEUTSCHE GOLD-UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Fr. 656,816, June 29, 1928.

**Decorating textile fabrics.** P. PEYRET. Brit. 302,328, Dec. 16, 1927. Decorations are made by application of a thin layer of a plastic material having a "mother-of-pearl effect" such as "mother-of-pearl lacquer." Solvents such as Et lactate, EtOH, MeOH, EtOAc, and the like may be used and cellulose acetate may be included in the lacquer.

**Coating natural textile materials with regenerated cellulose, etc.** L. LILIENFELD. Brit. 302,115, June 20, 1927. Yarns or fabrics such as those of flax, hemp, linen, ramie, jute, cotton or wool are dressed, sized or printed with solns. of cellulose (of which several examples are given) from which the cellulose may be pptd. or regenerated. A gas such as air, N, CO<sub>2</sub> or H<sub>2</sub> is emulsified with the cellulose soln. under pressure or substances such as an alkali carbonate, sulfite or sulfide are mixed with the soln. so that bubbles are formed in the coating material as regenerated or pptd. Sizing or softening agents, fillers or coloring substances, etc. also may be added.

**Design effects on fabrics containing artificial silk.** C. DREYFUS (to British Celanese, Ltd.) and G. RIVAT. Brit. 302,592, Dec. 16, 1927. Fabrics composed in part only of cellulose acetate or the like are treated in selected portions with pastes contg. inorg. acids or salts which attack cellulose acetate so that its selective removal from the fabric may be effected. Various auxiliary substances and treatments are described. Cf. C. A. 23, 2305-6.

**Ornamental effects on fabrics of cellulose acetate, etc.** C. DREYFUS (to British Celanese, Ltd.). Brit. 302,363, Dec. 16, 1927. Fabrics comprising cellulose acetate or other cellulose esters are locally treated with a saponifying agent such as KOH and then with a carbonizing soln. such as AlCl<sub>3</sub> or HCl by which the regenerated cellulose is removed. Cf. C. A. 23, 172.

**Ornamental effects on pile fabrics.** BRITISH CELANESE, LTD., G. H. ELLIS, H. C. OLPIN and E. E. WALKER. Brit. 302,208, Sept. 12, 1927. Selected portions of the

back of a pile fabric the pile of which comprises filaments of cellulose acetate or the like with a ground of other material are treated with a substance which will soften or weaken the cellulose deriv. pile filaments and the loosened pile is removed as by brushing or suction.

**Treating yarns and fabrics of cellulose derivatives.** BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 302,775, Nov. 2, 1927. Materials such as cellulose acetate products, other cellulose esters or ethers or "immunized cotton" are rendered more resistant to hot treatments such as ironing and given a good affinity for dyes by treating them with alk. solns. of Sn such as solns. of Na or K stannate.

**Artificial-silk fabrics.** C. DREYFUS (to British Celanese, Ltd.). Brit. 302,361, Dec. 15, 1927. Stiff fabrics are made of yarns of cellulose acetate or other org cellulose derivs. (with or without natural fibers) which are given a high twist and are preferably above 200 denier. Stiffening in some cases is effected by treatment of the fabric with ethylene dichloride or other suitable solvents, softening or swelling agents.

**Artificial silk.** RICHARD DIETSCHY. Fr. 657,007, July 4, 1928. Textiles, particularly artificial silk, are given a mat surface by loading them with insol. alk. earth salts such as  $\text{BaCl}_2$ .

**Artificial silk.** INOXI (S. A. R. L.). Fr. 34,071, May 14, 1927. Addn. to 639,197 (C. A. 23, 705). The crêpe effects on artificial silk, particularly acetate silk, is increased by dehydrating the silk as completely as possible before sizing.

**Relustering and printing artificial silk.** BLEACHERS' ASSOCIATION, LTD., W. KERSHAW, F. L. BARRETT and R. GAUNT. Brit. 301,567, Sept. 7, 1927. Pattern effects are produced on yarns or fabrics formed at least in part from fibers produced from cellulose esters, by a process including delustering and then effecting local regeneration by use of ethyl lactate (which may be applied in the form of a printing paste). Various details are given of the delustering process, etc. Brit. 301,568 relates to a similar process in which local regeneration is effected with ethylene glycol monoethyl ether.

**"Imitation linen."** RICARDO MIRET. U. S. 1,721,082, July 16. Cotton or a similar material is treated with a starching prepn. and the goods are then passed between stone calenders mounted so as to provide a slight slippage, at a high pressure. The calenders have slightly roughened surfaces so that they exert a slight gripping effect on the material.

**Felting woolen and similar fabrics incorporated with wool powder.** ETIENNE RICALES. U. S. 1,721,470, July 16. Fabric to be felted is repeatedly passed through a soap bath contg. in suspension wool powder and the latter is incorporated with the fabric by pressure (suitably by the action of rollers in an app. which is described).

**Repairing knitted or woven fabrics with patches of cellulose ester or other fabric applied by heat and pressure.** W. STELKENS and C. LIEDTKE. Brit. 302,858, May 11, 1928.

**Extraction and treatment of neutral greases from wool-washing baths.** E. MERTENS. Belg. 355,533, Dec. 31, 1929. The grease-charged wash-water is circulated through troughs in which paddle wheels are rotated so as to form a scum in which the grease concentrates. The scum is drawn off into a sep. trough, where a fine spray is played on it, the impurities are sepd., and the scum is then treated in an autoclave to give anhyd. and deodorized grease.

**Wetting and emulsifying substances, etc.** I. G. FARBERNIND. A.-G. Brit. 302,258, Sept. 8, 1927. Condensation products such as those produced from 1,3-butyleneglycol (or ethylene glycol or ethylene glycol monoalkyl ether) by heating with chlorosulfonic acid and naphthalene (or chlorinated, nitrated, hydrogenated or other substitution products of naphthalene or other hydrocarbons) may be used in acid, neutral or alk. baths such as those employed for washing, fulling, dyeing, printing, carbonizing, dressing, mercerizing, greasing, bast scouring, oiling, spinning, larding, sizing, bleaching, impregnating, tanning, destroying pests and in producing plastic compns.

**Sulfonated oils.** ORANIENBURGER CHEMISCHE FABRIK A.-G. Fr. 657,220, July 10, 1928. See Brit. 293,806 (C. A. 23, 1765-6).

**Treating covers for aircraft.** KARL HÜRTLE (to Goodyear Zeppelin Corp.). U. S. 1,721,302, July 16. A moisture-repelling material such as paraffin or Al oxide is applied to the inside surface of the cover only, the cover is secured under tension to the framework of an airship and the outer surface is subsequently coated with a protective contractive dope.

**Waterproofing and flameproofing composition for use on textile fabrics.** FRANK I. ROMAN (to Western Elec. Co.). U. S. 1,720,747, July 16. A compn. suitable for use on textile fabrics comprises a 30% rubber latex 75, a 25%  $(\text{NH}_4)_3\text{PO}_4$  soln. 300 and  $\text{NiH}_4$  polysulfide 1 part.

**Fireproofing composition.** TAISAN SHIGA (to Tei Kawata). U. S. 1,720,926, July 16. A compn. suitable for use on fabrics is prepd. by mixing a soln. of  $\text{NH}_4$  phosphate and  $(\text{NH}_4)_2\text{SO}_4$  in water with a clear soln. of Mg borate in boric acid soln.

**Purifying gasoline, etc., used for "dry cleaning."** CAMERON MACLEOD (to Baeuerle & Morris, Inc.). U. S. 1,720,604, July 9. Liquid contg. soaps and other impurities is vaporized *in vacuo* and impurities are sepd. by centrifugal action in an app. which is described.

## 26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

**The 4th paint meeting in Munich.** A. EIBNER. *Farben-Ztg.* 34, 2183-5, 2239-43, 2295-8, 2350-2 (1929).—A review of the papers on drying oils presented at the 1929 meeting of the V. D. I. at Munich.

**Progress in paints.** ZYGMUNT KLONOWSKI. *Przemysl Chem.* 13, 199-203 (1929). A brief review of the theory of drying of linseed oil and similar paints, and of testing them.

**White paints.** J. S. AABYE. *Kem. Maanedstid Nord. Handelsblad Kem. Ind.* 10, 22-8 (1929).—The durability as regards weather was examd. for zinc white, lead white, Kronos titanium white Standard A, Timonox white G. S. 1., a German and a Dutch lithopone and mixts. of these contg. lime and  $\text{BaSO}_4$ . Titanium white and Timonox white were found to be most durable and can be recommended in cases where there is no danger that the paint will be rubbed off.

**The significance of radio in paint technology.** PAUL NETTMANN. *Farben-Ztg.* 34, 2238-9 (1929).—The use of radio app. in certain tests is suggested. *E. g.*, the change in the dielec. const. of a film drying on the plate of a condenser could be followed. The charge on spray particles could be measured in a Faraday cage and the effect of radiations on films could be noted by the use of a Geiger ionization chamber.

**Film-forming solids in house paint.** ANON. Am. Paint & Varnish Mfrs'. Assoc., *Circ.* No. 351, 491-8 (1929).—Standard high-grade house paints contain approx. 90% by vol. of film-forming material (oil and pigment) while many low-priced inferior paints contain as low as 55% of film material. These facts account for the inferior service of the latter products. The analysis of 6 low-priced paints disclosed important discrepancies between the formulas on the containers and the actual compn.

**Pigments.** H. BRAIDY. *Cuir tech.* 18, 22-4, 47-51 (1929).—A description.

**Titanium oxide pigments.** A. VILA. *Tech. moderne* 21, 397-402 (1929).—A review of the history, sources and manuf. of these products.

**A new ultramarine oven.** M. A. AISENBUD. *Farbe u. Lack* 1929, 310-11. Instead of entering the oven directly through the floor, the hot gases, after passing through a network of flues along the sides and top, enter through a passage in the dome. Better distribution of heat is claimed.

**The effect of rubbing down and scraping by dry process of lead-painted surfaces of iron and steel structure.** L. C. MCNATR AND C. W. PRICE. *J. Ind. Hyg.* 11, 175-81 (1929).—An analysis was made of the air close to the mouth of workers engaged in dry-chipping, scraping and wire-brushing lead-painted iron and steel work. The amts. of Pb found were influenced greatly by the location factor and ranged between 0 and 194 mg. per 10 cu. m. of air. Four samples of paint debris were analyzed for total Pb and Pb sol. in 9.25% HCl, the sol. Pb amounting to 41.2-62.2% of the total Pb present. When the processes were carried out in the open, the amt. of Pb in the air was small and supposedly harmless. The amt. of Pb was much greater with indoor work and high enough to be injurious to health. Chipping and scraping are less dangerous than wire-brushing. The Pb inhalation is not assumed to decrease when the surface of the structure is wetted with linseed oil before wire-brushing. Turpentine is likely to give better results but its use is not feasible because of different obstacles.

**Coatings to protect against rust.** JULIUS BRAUN. *Metallbörse* 19, 1239-40 (1929).—A review of customary rust-preventing paints.

**Study of protective coatings for interior of steel tanks and underground pipe lines.** J. H. DAVIDSON, *et al.* *Am. Ry. Eng. Assoc. Proc.* 30, 143-53; *Ry. Eng. and Maintenance* 25, 244-7 (1929).—A coating of portland cement grout, prepn. of a petroleum base into which rust-inhibiting chemicals have been compounded or asphaltic liquid paints appear to have given better results for protection on the interior of steel water tanks

than red lead and linseed oil customarily used. In underground pipe lines, records indicate that portland cement is much the best, bituminous coatings wrapped are next and paint coatings give the lowest increase in life.

**Blooming (of coatings).** ROBERT BÜRSTENBINDER. *Farbe u. Lack* 1929, 323.—Tarnishing, blooming or blushing is caused by a variety of conditions, but principally by the presence of free fatty or resin acids formed by the hydrolysis of metallic soaps. Any condition, e. g., presence of alcs., which tends to inhibit this hydrolysis, reduces the formation of bloom. The formation of bloom is less with fused than with pptd. driers.

**Climatic effects on the quality of linseed oil.** WITOLD PŁOSKI. *Przemysł Chem.* 13, 167-8(1929).—On the basis of expts. extending over a period of some 14 yrs. Ivanov (C. A. 22, 4149) concluded that the chem. compn. of linseed oil characterized among other ways by  $I_2$  value changes markedly in relation to climate. Not only geographical latitude but also longitude and altitude affect its content of unsatd. bonds. The  $I_2$  value increases in the South-North direction at about the rate of 2 units per degree latitude for linseed oil, 0.65 units for rapeseed oil, and 1.3 units for sunflower seed oil. Furthermore flaxseed from the North is more vigorous than that from the South. P explains the preferential demand for Polish linseed oil before that from La Plata on the basis of the above observations of Ivanov. Cf. Leppert, C. A. 23, 2048.

**The course of stand oil formation.** H. MUNZERT. *Farben-Ztg.* 34, 2298-2300 (1929).—There are tabulated a no. of const. for linseed oil sampled at hourly intervals during its conversion to stand oil at a temp. of 290-300°.

**Solvent production and the lacquer industry.** J. G. DAVIDSON. *Chem. Markets* 25, 44-6(1929).

**Nitrocellulose for lacquers.** A. D. LUTTRINGER. *Mat. grasses* 21, 8392-3, 8483(1929).—A review of the manuf. of this product.

**Properties of the "yellow lacquer."** HOYO YASUDA. *Bull. Exptl. Lab. of Government of Korea*, 10, 15-20(1928).—The yellow lacquer is a yellow juice obtained from *Gilbertia trifida* Makino, and used as a paint for house-hold utensils and the Korean fan and has no poisoning action on the skin. The constituents are 24.22%  $H_2O$ , essential oil 14.95, resinous matter 51.8, rubber-like matter 1.79, insol. matter 6.71. The chief constituent is the resinous matter and may be regarded as a natural lacquer.

**Rapid testing of varnish raw materials (resins).** HANS BRENDL. *Farben-Ztg.* 34, 781-3(1929).—The acid and sapon. values, soly. in selected solvents and specific color reactions are usually sufficient to establish the identity and quality of the common resins. The following resins are discussed: rosin, copals, dammar, benzoin, acaroid, elemi, mastic, sandarac, shellac and asphalt.

**A new method for the determination of the melting point of resins.** THOS. H. DURRANS. *J. Oil and Colour Chem. Assoc.* 12, 173-5(1929).—Three g. of resin is melted in a test tube (15 cm.  $\times$  17 mm.) in a bath of  $H_2SO_4$ . The thermometer with a bulb long enough to extend above the melt is inserted in the molten resin. The tube is then withdrawn from the bath and, when the resin has hardened, exactly 50 g. Hg is poured on to it. The tube is then replaced in the bath which is so heated that the temp. rises 2° per min. The m. p. is the temp. at which the resin first appears above the Hg. Some typical results are given.

Co determination in driers, japans, etc. (HEIM) 7. Recovery of volatile solvents [in production of lacquers] (Brit. pat. 302,297) 13. Paints (Fr. pat. 657,512) 20. Plastic compositions [lacquers] containing cellulose esters or ethers, etc. (Brit. pat. 302,615) 18. Printing with non-drying inks (U. S. pat. 1,721,397) 18. Flexible floor and wall-covering material (Brit. pat. 301,901) 20. Ethers of cellulose and starch [for lacquers] (Brit. pat. 302,191) 23. Emulsions of [resins, waxes, etc.] (Brit. pat. 302,761) 13.

BIANCHI, C.: **Cellulose Varnishes (in Italian)**. Milan: V. Hoepli. 324 pp. L. 35. Reviewed in *J. Oil Colour Chem. Assoc.* 12, 177(1929).

HENGVELD, H., et al.: **Practical Railway Painting and Lacquering**. Chicago: Finishing Research Labs., Inc., New York: Simmons-Boardman Pub. Co. 242 pp. \$3 50.

**Paints.** JUANA M. NOVELLAS NÉE GUASCH. Fr. 657,276, July 11, 1928. Examples of paints contain (1) soln. of celluloid (10%) 80, castor oil, 5, soln. of callithrix

or thuya resin (30%) 10, soln. of oxidized terrene (30%) 5g. (2) soln. of celluloid (50%) benzoic acid 1, salicylic acid 1, castor oil 5, soln. of resin (30%) 8, soln. of oxidized terrene (30%) 7g. The latter has an antiseptic character.

**Paint for stenciling signs with an air-brush.** E. O. CASTLETON. Brit. 301,683, March 10, 1928. A water-sol. paint is used consisting of a color pigment, previously ground in water, mixed with casein, borax, aq.  $\text{NH}_3$ , turpentine and a material such as eucalyptus oil for preventing decompn. of the casein.

**Plastic paint.** ARTHUR MILLS. U. S. 1,720,135, July 9. A paint which may be used as a wall finish is composed of 70 parts of a mixt. formed of lithopone 65, powdered mica 7, silica 7, portland cement 3 and plaster of Paris 18% and 39 parts of a mixt. formed of linseed oil 41, "mineral spirit" 55, dryer 3 and moisture 1%.

**Titanium paints and pigments.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION (to Soc. de produits chimiques des Terres Rares). Brit. 302,659, Dec. 19, 1927. Ti paints and pigments comprise  $\text{TiO}_2$  sepd. from  $\text{H}_2\text{SO}_4$  solns. and dehydrated by heat, and preferably 10–30%  $\text{BaCO}_3$ , with or without dilg. substances.

**Pigments.** AKT.-GES. GEORG EGESTORFF'S SALZWERKE UND CHEMISCHE FABRIKEN. (Robert Müller, inventor). Ger. 478,119, Apr. 16, 1921. Red pigment contg. Fe are prepd. by treating a concd. soln. of a ferrous or ferric salt with a hydroxide or carbonate of an alkali or alk. earth metal, treating the pptd. hydroxide, if desired after aeration, with a soln. of a ferrous or ferric salt, and washing and calcining.

**White lead.** FRANK T. BAILEY and WILSON AUSTIN. U. S. 1,720,196, July 9. An aq. mixt. of Pb oxide and HOAc is introduced into a closed container in which it is whipped in atm. suspension while the container is revolved, and a controlled circulation of air and of  $\text{CO}_2$  through the container is maintained. An app. is described. Cf. C. A. 22, 1862.

**Mill for grinding paints, etc.** A. E. G. MACCALLUM. Brit. 301,781, Sept. 5, 1927. Structural features.

**Manufacture of artificial drying or semi-drying oil, and product obtained thereby.** A. DE CARVALHO. Belg. 355,353, Nov. 30, 1928.  $\text{O}_3$  is passed through the oil at a temp. of about 130–50°.

**Printing inks.** I. G. FARBENIND. A.-G. Fr. 657,516, July 16, 1928. Printing inks which may be decolorized so that the paper may be reused have a basis of acid dyes for wool, taken in an insol. form, either alone or mixed with colored lakes or suitable dyes. In an example, black Agalma 10 BX is dissolved in water and  $\text{BaCl}_2$  is added, the pptd. lake being filtered off and mixed with a varnish for printing. Paper printed with this ink is decolorized by  $\text{NaOCl}$ .

**Treatment of printing press rolls.** L. DEJARDIN. Belg. 355,723, Dec. 31, 1928. In order to prevent the ink from drying on printing press rolls when they are not running, they are treated with mixt. of 1 part spirits of turpentine and 2 parts castor oil, contg. 5 g. of oil of cloves per l.

**Lacs and varnish.** I. G. FARBENIND. A.-G. (Hans Grotowsky, inventor). Ger. 477,618, Apr. 5, 1927. A varnish is colored by the condensation products of pyrazolone with aromatic aldehydes. In the example, a light-fast orange varnish is obtained by adding the condensation product of *p*-diethylaminobenzaldehyde and phenylmethylpyrazolone.

**Nitrocellulose lacquer.** GERALD R. BARRETT (to Merrimac Chemical Co.). U. S. 1,720,992, July 16. A lacquer is formed contg. an oxidizable resin such as rosin glycerol ester together with nitrocellulose soln., pigment and hydroquinone in a concn. of about 0.5–1.0% of the oxidizable resin. The hydroquinone serves to inhibit oxidation.

**Nitrocellulose lacquers.** I. G. FARBENIND. A.-G. Brit. 302,390, Sept. 15, 1927. Non-inflammable nitrocellulose lacquers are prepd. by adding to the lacquers methyl chloride with or without ethylene chloride in quantity at least equal to that of the nitrocellulose solvents which are present. Numerous other possible constituents of the lacquers also are mentioned.

**"Dope materials" containing cellulose esters.** I. G. FARBENIND. A.-G. Brit. 302,280, Dec. 13, 1927. Materials for use in producing non-transparent coatings, comprising cellulose esters such as nitrate or acetate, softening or gelatinizing agents and coloring substances (of which examples are given) with or without other materials are subdivided and mixed as by rollers under pressure without bringing the coloring matter into colloidal condition. The pliant elastic products may be dissolved in low b. p. solvents to form lustrous varnishes. Oil also may be added.

**Resins.** A. SCHULTZE & Co. Fr. 657,114, July 6, 1928. Resins obtained from dead wood are improved by distn. under high vacuum.

**Phenolic resin.** FRAZIER GROFF and GEORGE W. MILLER (to Bakelite Corp.).

U. S. 1,720,895, July 16. A fusible non-reactive resinous reaction product is formed from a fusible phenol-methylene resin, a basic condensing agent such as lime, caustic alkali or alkali carbonate and furfural. The product is suitable for use in molding compns. Cf. 23, 4090.

**Phenolic resins.** BRITISH DYESTUFFS CORP., LTD. Fr. 656,647, June 29, 1928. Resinous condensation products of PhOH are purified by partial or entire elimination of the phenols and sol. products by extn. with a solvent such as water after incorporating in the resin a filling material such as sawdust, cotton waste or asbestos. The extn. with water is preceded and followed by an adjustment of the H-ion concn. to  $p_H = 3.5$  to 7.

**Resinous condensation product of phenol and cellulose.** EMIL E. NOVOTNY and CHARLES J. ROMIEUX (to John S. Stokes). U. S. 1,721,315, July 16. A mixt. comprising only a phenolic compd. such as PhOH and cellulose is heated to above  $120^\circ$  (suitably about  $250^\circ$ ) to cause reaction and formation of a sol. fusible resinous condensation product which may be further modified by use of  $NH_3$ ,  $CH_2O$ ,  $(CH_2)_nN_4$ , furfural, etc.

**Press masses from phenol-formaldehyde resins.** FRITZ SEEBACH (to Bakelite G. m. b. H.). U. S. 1,720,062, July 9. Unstable colloidal solns. of phenol- $CH_2O$  resins are mixed with fillers such as wood meal or paper pulp and the resins are pptd. in a pure finely divided form by use of water without decreasing the basic content of the soln.

**Urea-formaldehyde condensation products.** I. G. FARBERIND. A.-G. Brit. 301,696, Nov. 6, 1926. Instead of using dimethylolurea as a starting material, in the process described in Brit. 261,029 (C. A. 21, 3431), there are used products of higher mol. wt. obtained from it by "cautious treatment" with an alk. reagent. Lacquers or resinous or glass-like masses are obtained depending on whether or not the solvent is allowed to remain in the product. Various specified fillers, etc., may be added. Cf. C. A. 23, 678.

**Phenol-formaldehyde condensation products.** E. S. HOLE. Brit. 302,098, June 20, 1927. A water-sol. condensation product is made by boiling together PhOH and  $CH_2O$  in the presence of a small quantity of an alk. condensing agent, adding water, cooling and further adding water contg. a chromic acid salt. Methods described in Brit. 278,460 (C. A. 22, 2645) may be employed. The product is suitable for use in varnish or impregnating compns.

**Moldable composition.** HARRY M. WEBER (to Ellis-Foster Co.). U. S. 1,720,406, July 9. A compn. which is suitable for hot molding comprises a resin of insufficient fusibility such as a phenol-aldehyde resin, a filler and a small proportion of an added hexamethylenetetraminetriphenol which acts as a flux for the resin.

**Moldable composition.** ARCHIE J. WEITH and ORTO HOLZMAN (to Bakelite Corp.). U. S. 1,720,192, July 9. A compn. which is suitable for hot-press molding comprises a potentially-reactive resin such as may be formed from phenol and  $CH_2O$ , a fibrous cellulose ester such as cellulose acetate and a phenyl ester such as mono-phenyl dicresyl phosphate.

**Synthetic resins.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 302,737, Dec. 21, 1927. Water-insol. resins are obtained by adding to a urea- $CH_2O$  reaction mixt., before or at any stage of condensation, in an alk. medium, a substance capable of forming with  $CH_2O$  or its condensation products in the presence of OH ions a water-insol. resin, and heating. Some of the substances which may be added are given. Alc.-sol. products suitable for making lacquers may be obtained, and the resins obtained are suitable for use with basic pigments.

**Synthetic resins.** BAKELITE CORP. Fr. 656,748, Nov. 14, 1927. Polymerization of synthetic resins is carried out in an oven with an entry for heated air under pressure and an exit for vapors of all kinds to prevent the harmful action of the vapors on the resins after polymerization.

**Article made from artificial resins.** SAÜRESCHUTZ G. M. B. H. (Johann K. Wirth, inventor). Ger. 477,836, Apr. 4, 1926. Tubular structures are made from the artificial resins, obtained by condensing phenols with HCHO, by molding when plastic.

**Joining surfaces of artificial resins.** AMBRASIT-WERKE KUNSTHARZFABRIK G. M. B. H. Austrian 113,524, June 15, 1928. Paper or the like impregnated with a reactive artificial resin is interposed between the surfaces to be joined and the union is then heated to  $80$ – $90^\circ$  in a press. The reactive resin may be partly hardened before use. The method is particularly intended for resins of the Bakelite type.

## 27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

**Cacao butter** (*Oleum cacao*). SCHELLBACH. *Pharm. Ztg.* **74**, 875-6(1929).—This product is considered from the standpoint of the Ger. Food Law of July 5, 1927, notably the methods and sources of recovery, phys. consts., etc. W. O. E.

**Emulsions of fats and hydrocarbons and their industrial applications.** LOUIS MEUNIER. *Cuir tech.* **18**, 64-72, 88-94(1929).—See C. A. **23**, 2052. J. G. N.

**Turbidity time numbers and solidifying point of solid fats, especially of cacao butter.** W. SPRINGER. *Chem. Umschau Fette, Oele, Wachse u. Harze* **36**, 165-7(1929).—The app. used is a squatly flask with inlet and outlet for  $H_2O$  and a tubulure for a thermometer; it carries in its neck a titer tube, 23 mm. diam. and within this a 19 mm. titer tube and another thermometer; the 19-mm. tube has a vertical blue line, 1 mm. wide, at its back. The flask is filled with  $H_2O$ , kept at  $20^\circ$ , and the space between the 2 titer tubes is filled with "vaseline oil." Method: Neutralize 100 g. of cacao butter with 2 g.  $MgO$ , filter, remove the 19-mm. titer tube, place 10 cc. of the filtered cacao butter in it, heat to  $50^\circ$ , replace, stir with the thermometer until the blue line becomes invisible, using a 25-watt light in the background. The time interval in sec. between start and finish is noted by means of a stop watch. Continue the test without stirring and note the highest temp. reached by the thermometer. The time interval between the turbidity point and the highest temp. point is expressed in min. In some cases different results are obtained; the test is then immediately repeated. Results are tabulated for various cacao butters, varying in turbidity point between 510 seconds for pure, pressed cacao butter and 1140 seconds for hull-extd dark cacao butter, and between 75 min. and 265 min. in the titer time in the first test. The 2nd detn. varied between 450 and 1020 sec. and 66 and 233 min., resp. American lard (2nd test) showed 360 seconds for turbidity and 8 min. for titer; tallow 75 sec and  $1\frac{1}{4}$  min.; hardened fish oil 90 sec. and  $1\frac{1}{2}$  min. and hardened coconut oil 330 sec and 9 min. P. ESCHER

**The unsaturated fatty acids of chrysalis oil.** WASABURO KIMURA. *Chem. Umschau Fette, Oele, Wachse u. Harze* **36**, 185-90(1929).—See C. A. **22**, 2478. P. E.

**Colorimetry of oils and fats.** G. GREITEMANN. *Chem. Umschau Fette, Oele, Wachse u. Harze* **36**, 167-8(1929).—Lovibond's tintometer is the standard instrument for international trade, but is too expensive for general use; likewise Zeiss' "Stufen-photometer" which measures the light permeability of the spectrum. It is proposed to measure the intensity of the color rather than its exact tint, by comparison with I soln. in KI of 25 mm. depth, contained in sealed glass tubes. The color no. then expresses the no. of mg. of free I in 10 cc. KI soln., measured in a layer 25 mm. deep. P. E.

**Gas masks in the oil and fat industry.** O. NEUSS. *Chem. Umschau Fette, Oele, Wachse u. Harze* **36**, 190-3(1929).—I. A description of the Degea gas mask is given with the absorption by wt. and vol. of acetone, benzene, phosgene,  $SO_2$ ,  $HCl$ ,  $Cl$ ,  $NH_3$ ,  $HCN$ ,  $H_2S$ ,  $PH_3$  and  $As_2H_3$ . P. ESCHER

**Combined oil refining methods.** K. LÖFFL. *Seifensieder Ztg.* **56**, 205-6(1929).—The "Wecker" method for removing free fatty acids (C. A. **23**, 2587, 3361) shows no advantage, since the removal of fatty acids by distn. down to  $\frac{1}{2}\%$  introduces an extra factory operation. P. ESCHER

**Bleaching dark oils.** M. DITTMER. *Seifensieder Ztg.* **56**, 210-11, 224-5(1929).—When the loss of color in oil refining or bleaching is judged, it is necessary to det. the oxidized acids by the petroleum ether method. If the fatty acids sol. in petroleum ether have a lighter color than the fat or oil itself, the preliminary purification and the refining must be carried far enough to approach the color of the fatty acids before any bleaching with fuller's earth is attempted; palm oil may be bleached directly without refining. Every bleaching or refining process should leave the "dirt" chemically unchanged, in order to ensure its normal behavior during the settling of the soap in the kettle. P. ESCHER

**Studies on decolorization of oil.** R. ERSBAK. *Kem. Maanedblad Nord. Handelsblad Kem. Ind.* **10**, 64-7(1929).—The use of aqueous solutions of methylene blue for detg. decolorizing power is criticized. Curves and tables are given for the decolorizing effect of floridin, Tonsil A. C. decolorizing carbon and mixtures of these on palm-kernel oil. KRISTIAN HØJENDAHL

**The regularity of the variations of the character of oils extracted from an animal as a function of the point of sampling.** L. MARGAILLAN. *Compt. rend.* **188**, 1630-2

(1929).—Studies on 3 varieties of the Delphinidae showed wide variations in the properties of oils selected from different parts of the same animal. These variations follow a definite order, the I no. increasing from the nose to the tail, except that near the eye, nose and mouth there are local variations. This regular variation is quite general.

AMY LEVESCONTE

**Iodine values on menhaden fish oil.** C. H. BANKES AND A. R. LANGE. *Oil & Fat Ind.* 6, No. 7, 31, 3(1929).—The Wijs and the Hanus methods were compared on 3 samples of oil contg. 2.75, 4.08, and 10.39% free acid, resp. The figures show that the Wijs method requires less time and the I nos. by both methods increase relatively to the time allowed for I adsorption. The Wijs method is more reliable and faster than the Hanus.

E. SCHERUBEL

**Report of committee on crude mill operations.** A. K. SCHWARTZ, *et al.* *Oil & Fat Ind.* 6, No. 7, 20–1(1929); cf. *C. A.* 22, 2674.—Two cooking conditions were established representing a variation in rate of heating, time of cooking and amt. of  $H_2O$  added to an extent liable to occur in ordinary mill operation. The results confirm the generalization that the most important cooking factor governing the quality of the oil is the rate of heating of meats, that governing the extent of extn. being the time of cook with a corresponding increase or decrease in the  $H_2O$  of the meats.

E. SCHERUBEL

**Report of the Kreis test committee.** A. S. RICHARDSON, *et al.* *Oil & Fat Ind.* 6, No. 7, 28–9(1929).—Six wintered cottonseed oils were studied from the viewpoint of uniformity of the Kreis test, its value as an index of the degree of rancidity, as well as the degree of rancidity developed after further exposure of the samples to air. The results obtained varied widely; and the most significant result to date is the failure of different labs. to agree on whether the Kreis test is pos. or neg. for a given sample. The av. grading of the samples fails to show any relation between intensity of the test and rancidity or quality of the oil as judged by flavor, but no definite conclusion can be drawn from the erratic results obtained.

E. SCHERUBEL

**Methods for cottonseed analysis.** G. S. JAMIESON AND R. S. MCKINNEY. *Oil & Fat Ind.* 6, No. 7, 11–3(1929).—The results of work on the following detns. are discussed: moisture,  $NH_3$ , free acid and oil in seed.

E. SCHERUBEL

**By-products in manufacturing abietic essential oils. Abietic extracts.** P. A. BOBROV. *Zhur. Prikladnoi Khim.* 1, 189–94(1928).—Abietic exts. can be consumed by the tanning industry.

V. KALICHEVSKY

**Sulfonated oils. I. Preparation of pure sodium salt of the acid sulfate of ricinoleic acid and its isolation from commercial sulfonated oils.** KYOSUKE NISHIZAWA AND KINZIRO WINOKUTI. *Chem. Umschau Fette, Oele, Wachse Harze* 36, 79–81(1929).—The Grün-Wolzenberg's method (*C. A.* 3, 1749) was followed for prepg. pure sulfuric ester. The Ba salt was prepd. from its aq. soln. and the free acid sulfate of ricinoleic acid liberated with strong acid as a yellow oil. An alc. soln. of this was neutralized with NaOH, the pptd.  $Na_2SO_4$  filtered off and the filtrate crystd. at low temp. repeatedly. The final product was rhombic needles, belonging optically to the biaxial positive crystals, showing extinction between crossed nicols. It is very hygroscopic, sol. in  $H_2O$  and nearly insol. in org. solvents. It is difficultly sol. in 98% alc., but lesser concns. of alc. and high temps. increase its soly and this fact was utilized for further purification of the Na salt of the acid sulfate of ricinoleic acid (I),  $(CH_3(CH_2)_7CH(OSO_3Na)CH_2CH:CH(CH_2)_7COONa)$ . On account of retarded crystn. through foreign admixtures it is not possible to obtain the I by neutralizing an alc. soln. of the sulfonated oil with NaOH. But by adding HCl and ether to the sample ("Monopol" oil, "Monopol soap and Turkey red oil") and with above method as modified by N. and W. good results were obtained in isolating I, proving that this acid is actually present in com. sulfonated castor oils. II. **Saponification of the acid sulfate of ricinoleic acid or its sodium salt.** *Ibid* 97–102.—N. and W. investigated systematically the reaction when sapon. pure I, alone and in the presence of acids and alkalis. Sapon. was complete with  $N$  HCl in 25–30 min. and with 2  $N$  HCl in 15–20 min. at  $100^\circ$ . With  $N$   $H_2SO_4$  sapon. is complete at  $100^\circ$  in 40–50 min. and with 2  $N$   $H_2SO_4$  in 20–30 min. The organically combined  $H_2SO_4$  in sulfonated oils can be found by titration after boiling with the proper quantity and proper concn. of  $H_2SO_4$ . The aq. soln. of the Na sulfate of ricinoleic acid is neutral toward methyl orange. The free ester in its  $H_2O$  soln. is salted out as the acid salt by large addns. of NaCl, etc.; and during the sapon. the  $HSO_3$  group is split off as  $NaHSO_4$  and not as  $H_2SO_4$  as stated by Herbig. The stability of the Na salt of the ester was tested by keeping a 0.1  $M$  aq. soln. for 5 hrs. in the thermostat at  $75^\circ$ , showing 2.86% sapon. and at  $100^\circ$  18.54%. Addn. of 10  $N$  NaOH at  $100^\circ$  as in the manuf. of "Monopol" soap caused only a trace of  $BaSO_4$  ppt. after 1 hr. 0.93  $N$  NaOH after 5 hrs. caused 12.55% and 4.54  $N$  NaOH only 5.64% sapon., thus showing a fair stability toward OH ions

but instability toward H ions. In alc. NaOH soln. the salt is more stable in weak in concd. solns.

**The sodium hydroxide saponification number.** W. NORMANN. *Chem. Umschau Fette, Oele, Wachse u. Harze* **36**, 197-8(1929).—For convenience of factory use the sapon. no. of oils and fats should be expressed in terms of NaOH. Tables of these nos. and of "free fatty acids" are appended.

**Glycerol in the oil and soap industry.** J. LEIMDORFER. *Seifensieder-Ztg.* **56**, 208-10(1929).—It is now possible to combine fatty acids with glycerol in a homogeneous system at low temp.; no details of the method are given.

**Proposed methods for the examination of waxes and wax products.** BUCHNER. *Chem. Umschau Fette, Oele, Wachse u. Harze* **36**, 203-8(1929).—An addnl. set of proposed analytical methods, issued by the German Commission for Fat Analysis, is given in full.

**Metal soaps and their uses.** HANS J. BRAUN. *Metallbörse* **19**, 1461-2(1929).—Soaps contg. Cu, Mg, Zn, Cd, Hg, Ca, Ba, Al, Pb, Bi, Cr, U, Mn, Fe, Ni and Co are described.

**Potash soaps and liquid soaps.** EUGENE SCHUCK. *Am. Perfumer* **24**, 221-3, 279-80(1929).—The manuf. of potash soaps is discussed. In making a coconut oil base soap 24 to 25 lb. of KOH per 100 lb. oil is used in place of the theoretical 28 lb., as the latter would make the soap too strong. The chem. properties of a base soap for liquid soap are low free KOH, low unsapond. oil, absence of sugar and alc., a specified % H<sub>2</sub>O and min. insol. in alc. Expts. show that soaps with low % of anhyd. soap filter rapidly, and carrying with them a large amt. of K stearate on account of their higher diln., are more sensitive to changes in temp than the concd. solns.

**Triethanolamine soaps in toilet preparations.** RALF B. TRUSLER. *Aromatics* **10**, No. 5, 27-9(1929).—The prepn., properties and application of these soaps are discussed.

**Carbon dioxide and soap in water-alcohol mixtures.** O. SCHÜTTE. *Seifensieder Ztg.* **56**, 85-6, 93-4(1929).—Ald. solns. of pure fatty acids were sapond. under reflux with 10 N KOH. After neutralization with 2 N AcOH, washed CO<sub>2</sub> was passed through at 20° for 15 min. Ppts. of the compn. 1 mol. acid and 1 mol. K salt of fatty acid were formed for stearic, palmitic, myristic and erucic acids. Oleic, linolic and lauric acids did not yield any soap ppt. under these conditions. Dioleate of K could only be obtained by pptn. at 0°. Hardened fat in tallow can be detected by CO<sub>2</sub>: 5 g. fat is saponified with 65 cc. alc. and 6 cc. 10 N KOH; neutralized with AcOH and filled up to 130 cc. with H<sub>2</sub>O. Through this soln. is passed a rapid stream of washed CO<sub>2</sub> at 8-10° for 15 min. The ppt. of acid soaps is filtered with suction through coarse-pored filter; washed once with 50% alc. (vol.) at 8-10°; dissolved in 65 cc. warm alc., neutralized with 2 N KOH, filled with H<sub>2</sub>O to 130 cc. and pptd. with CO<sub>2</sub> as before at 8-10° for 15 min.; filtered; and washed 3 times with 50% alc. The fatty acids are liberated and the I no. is detd. If the I no. lies above 10, an addn. of 15% or more of hardened fat is established. The I no. of the solid acids of 5 tallows by above method ranged from 5.6 to 7.6 and those of hardened fish and peanut oil from 30.24 to 67.44.

**Detoxifying, diffusing, germicidal and surface-tension-depressing properties of soaps.** FORREST R. DAVISON. *J. Infectious Diseases* **43**, 292-9(1928).—Twelve common soaps were prepd. and the above properties studied. Castor oil, coconut oil, linseed oil and cottonseed oil soaps have the highest detoxifying ability, the highest germicidal ability, an outstanding dialyzing ability but are correspondingly ineffective surface-tension depressants.

**Colloidchemical changes in fatty oils (AUER) 30.** Detection of water in oil (Ger pat. 477,639) **22.** Emulsions of oils (Brit. pat. 302,761) **13;** (Brit. pat. 301,805) **22.** Purifying oils (Fr. pat. 656,728) **23.** Montan wax [bleaching other waxes] (Brit. pat. 302,626) **21.** Separator for oil and water (Austrian pat. 113,339) **1.** Extraction and treatment of neutral grease from wool-washing baths (Belg. pat. 355,533) **25.**

**Fatty acids.** RAYMOND VIDAL. Fr. 34,067, May 10, 1927. Addn. to 637,271 (C. A. **23**, 536). Fatty acids or fish and cetacean acid oils are heated before the treatment with aq. solns. of alkali hypochlorites or hypobromites.

**Fatty acids.** RAYMOND VIDAL. Fr. 34,097, June 17, 1927. Addn. to 637,274 (C. A. **23**, 536). A small amt. of a mineral or org. acid is added to the fatty acids, fatty acids and mineral oil, or animal, mineral or vegetable oil before the treatment with alkali hypochlorites or hypobromites.

**Extraction of oil from green palm fruit by liquid solvents with or without separation**

of the palm or palmetto oil. R. WALLON. *Belg.* 354,998, Nov. 30, 1929. A heavy liquid solvent is used, b. above  $100^{\circ}$ , and the extn. is carried out above  $100^{\circ}$  so as to evaporate the  $H_2O$  of the fruit.

Extraction of oil from green palm fruit by liquid solvents with or without separation of the palm or palmetto oil. R. WALLON. *Belg.* 355,473, Dec. 31, 1928. The process is carried out under partial vacuum, so that steam under pressure can be used to reduce the distn. of the solvent.

Extraction of oil from green palm fruit by liquid solvents with or without separation of the palm or palmetto oil. R. WALLON. *Belg.* 355,878, Dec. 31, 1929. An app. for carrying out the process is specified.

## 28—SUGAR, STARCH AND GUMS

J. K. DALE

Economies in sugar technology. J. HAMOUS. *Listy Cukrovar.* 47, 442(1929).—A discussion. FRANK MARESH

Manufacture of sugar according to the New Oxford Process. ODON VAJDA. *J. fabr. suc.* No. 49(1928).—A review. E. A. FIEGER

The presence of zinc in the products of sugar manufacture. O. SPENGLER AND K. ZABLINSKY. *Z. Ver. deut. Zuckerind.* 79, 251-42(1929).—The Zn content of sugar products is very much less than that of other food products, though it is present in most sugar-factory products. The zinc content of the beet itself is the source. Zinc-coated surfaces are very resistant to sugar liquors while tin-coated iron surfaces are impractical because they rust readily, darken the liquors and cause development of acidity. With Zn the  $p_H$  change was small. From this evidence it seems futile to forbid the use of zinc-coated app. in refineries. F. CAMPS-CAMPINS

Final reports 1928 of mill control and fuel control. ANON. *Arch. Suikerind.* III, *Mededeel. Proefsta. Java-Suikerind.* 1929, 137-230. P. R. PEKELHARING

Sugar-house and refinery raw sugars and massecuites. J. BERGÉ. *Chimie & industrie Special No.*, 641-7(Feb., 1929).—Refined sugar with a min. sucrose content of 99.50% can be obtained directly from raw sugar or massecuite by means of centrifugal force approaching 40,000 times gravity (1200-2500 times being normally employed). In certain exceptional cases, where concn. has been carried too far, the residual mother liquor forms a sort of a lacquer around the sugar, but by exposing to suitable atm. conditions the product may absorb sufficient moisture to permit of refining by centrifuging as above. Though the process has not yet reached the stage of industrial application and will first require further improvements, its commercial application is considered as assured. The merits of the process are briefly discussed. A. P.-C.

The use of the rotary tubular Lafeuille apparatus for the crystallization of sugar. M. LAFEUILLE. *Bull. assoc. chim. suc. dist.* 46, 155-9(1929).—The operating results of the rotary tubular Lafeuille crystallizer, and of the crystallizer pan are reviewed. F. CAMPS-CAMPINS

Conductivity control of the products of centrifuged sugar. V. NETUKA. *Listy Cukrovar.* 46, 564-6(1928).—Prior to using the cond. method, N. tried a polarimeter method of controlling the centrifuging process. Without technical control 60% of products fell outside the stipulated limits; with the polarimeter for control only 13% exceeded the limits. Cond. methods will be tried for this control. F. M.

The influence of planting, harvesting and age on the sugar and cane production of 2878 POJ during crop 1928. G. BOOBERG. *Arch. Suikerind.* III, *Mededeel. Proefsta. Java-Suikerind.* 1929, 289-458. P. R. PEKELHARING

The application of decolorizing carbons in the cane-sugar industry. P. HONIG & J. F. BOGTSTRA. *Arch. Suikerind.* III, *Mededeel. Proefsta. Java-Suikerind.* 1929, 231-88.—A historical review is given of the results obtained in Java with decolorizing carbons. These were favorable only on remelted sugars. Expts. were carried out at Somobito, a carbonation mill, the object being to find out if the quality of the sugar was improved by graining the first strikes on a soln. of final sugar in thin juice which had been clarified and decolorized. A soln. of final sugar in thin juice at 60 Brix was treated with lime and  $CaHPO_4$  simultaneously to 7.2  $p_H$  and heated to  $75^{\circ}$ . Hyflo Supercel was added and the soln. filtered through Scheibler filters then through four Scheibler filters, charged with 38 kg. carboraffin each. Total decolorization amounted to 50-60%. The chem. clarification and prefiltration removed considerable more colloids than the carboraffin filtration. Sugar boiled from the latter was of ex-

cellent quality, but sugar boiled from the prefiltered soln. was of equal quality if sufficiently well washed. The expts. did not show a correlation between the color of the soln. and the coloring matter incorporated in the crystals boiled from that soln.

**A new method for purifying the juices of sugar beets.** A. I. LITZYAGA <sup>nn</sup> *Weissruth. Staatl. Akad. Landw. Gorky* 7, 315-21(1928).—L. presents the method of *skatelo* for clarifying diffusion juice by satn. of limed juice with  $MgSO_4$ . A complete sepn. of the org. and inorg. impurities takes place. This treatment brings into the sugar juice some  $CaSO_4$ , and in the sugar one may find as high as 0.4% gypsum. This time-saving process eliminates several steps in the satn. process. J. S. JOFFE

**Diffusion experiments with dried sliced beets.** V. STANEK AND K. SANDERA. *Listy Cukrovar.* 47, 407-14(1929).—Beets from the Eynsham district (Bohemia) were sliced and dried. Diffusion was carried out in batteries of cells of 1 l. capacity. A very complete analysis of the beets, liquor and residue permitted a detn. of the distribution of the products especially N compds. Albuminoid N remains in the beet residue; other forms of N compds. are distributed as in the diffusion of fresh undried beets. The diffusion liquor is very acid and contains 2.2 pts. invert sugar to every 100 of sucrose. Drying did not decompose the amides as they appear in large quantities in both the diffusion liquor and residue. FRANK MARESH

**Plant reproductive cells. III. Constituents of the pollen grains of the sugar beet.** A. KIESEL AND B. RUBIN. *Z. physiol. Chem.* 182, 241-50(1929).—Sugar-beet pollen collected during 2 seasons gave the following proximate analyses: Total N, 5.25, 5.61; protein N, 3.55, 4.15; non-protein N, 1.70, 1.46; free fat, 4.56, 4.33; total fat, 10.92, 10.92; lecithin, 2.87; glucose, 0.85, 0.80; sucrose, 4.83, 5.34; maltose, 4.03, 3.36; starch, dextrin and hemicelluloses, 7.63, 8.99; ash, 7.26, 6.02%. The ash contd. 4.82, 5.15%  $CaO$ ; 21.2, 21.1%  $K_2O$ ; 6.61, 7.31%  $MgO$ . From the  $H_2O$  ext. a hydrocarbon  $C_{12}H_{22}$ , m. 61.5-63.5°, was obtained in a yield corresponding to 2% of the dry pollen. Its function is evidently to render the grains impervious to  $H_2O$ . The  $H_2O$  ext. contained about 40% lecithin as judged from its P and N content. Adenine was isolated in 0.04% yield. A striking observation was the high betaine content which amounted to 2.96% of the dry pollen or  $1/5$  of the non-protein N.  $Me_3N$  was not present as such. The occurrence of  $Me_3N$  reported by Stift must have resulted from decomposition of betaine during the analysis. The mother liquor from the betaine contained a small amt. of choline, which was identified as the chloroplatinate. A. W. DOW

**A process for rendering harmless the waste waters from a beet-sugar factory.** H. BACH. *Z. Ver. deut. Zuckerind.* 79, 241-50(1929).—Waste waters of beet-sugar factories introduced into streams, may cause the death of fish since they contain substances which combine with the oxygen dissolved in the water. The waters also contain substances toxic to fish but in too great diln. to cause trouble. Only the water from the diffusion battery and the presses is harmful. A remedy is aeration of the waste waters either before or after introduction into the stream. F. C. C.

**The removal of condensed vapors from distillates, vacuum pans and heaters without the use of sieves.** FR. PAULIK. *Listy Cukrovar.* 47, 481-2(1929).—A plant arrangement is discussed. FRANK MARESH

**Saturation.** J. DEDEK. *Listy Cukrovar.* 47, 495-500(1929).—A discussion. FRANK MARESH

**Sectional vacuum-pan system of A. A. Shumilov, Yu. D. Lyubchenko and R. R. Krauss.** E. R. KRAEVSKII. *Zhur. Sakharnoi Prom.* I, 356-72(1927). V. E. B.

**The advantageous zone of  $p_H$  for refinery liquors.** M. I. NAKHMANOVICH. *Nauk. Zapiski Sakharnoi Prom.* 7, 265-81(1929).—Refinery liquors adjusted to  $p_H$  values within the limits of 5.9 to 9.3 were heated. Refinery liquor slightly alk. or neutral to phenolphthalein, ( $p_H \approx 8$ ) increased in color on heating for 1 hr. at 95° or 2 hrs. at 85°. The danger of producing color is less at  $p_H$  from 8.0 to 7.0. At  $p_H$  7.0 heating 3 hrs. at 95° had no effect on the liquor. Destruction of sugar begins below  $p_H$  7.0. According to the expts.,  $p_H$  7.0 to 7.5 is the most advantageous zone for filtering refinery beet-sugar liquors. V. E. BAIKOV

**Saccharification of wood by weak acids.** E. DESPARMET. *Chimie & Industrie Special No.*, 571-7(Feb., 1929).—In lab.-scale expts. sawdust was hydrolyzed with 3-5 parts of 2-4%  $H_2SO_4$ , a pressure of 4-12 kg. per sq. cm., and a period of 3-30 min. The rate of formation of reducing sugars (essentially dextrose) was extremely rapid, reaching a max. in 3 min. The rate of destruction of dextrose was also rapid. At high pressures (about 12 kg), sugar yield plotted against pressure gave a curve showing a 2nd max.; this is explained as follows: wood contains 2 groups of polysaccharides hydrolyzed at different rates; the rate of hydrolysis of the 1st polysaccharide group is

very high and is little affected by pressure or acid concn. while that of the 2nd group is appreciably lower and is distinctly influenced by pressure and acid concn. Three-min. hydrolysis with 3 vols. of 2%  $H_2SO_4$  at a pressure of 8 kg., washing with  $H_2O$ , followed by a 5-min. hydrolysis with 3.7 vols. of 4%  $H_2SO_4$  at 12 kg., gave a total yield of 36.5% reducing sugars, with a simultaneous loss in wt. of 47.6%. The hypothesis of the existence of 2 types of polysaccharides in wood is sustained by the fact that prolonged hydrolysis (30 min.) at low pressure (about 8 kg.) gives a residue resembling the original sawdust, while short hydrolysis (5 min.) at high pressure (12 kg.) leaves a fine powder of much smaller vol. and higher d. than the original sawdust.

A. PAPINEAU-COUTURE

The use of sugar-cane waste products as cheap and effective larvicides (RICKARD, *et al.*) 15. Spray drying (for molasses and sugar) (NYROP) 13. An apparatus for removing foams from samples of liquors (HERNYCH) 1. Factors in the estimation of starch by the I method (LEPIK) 7. Sulfonated carbohydrates (from starch) (Fr. pat. 657,204) 23. Carbohydrate (starch) derivatives (Fr. pat. 656,861) 23.

Apparatus for purifying starch-converted dextrose solutions by electrolysis and osmosis. CORN PRODUCTS REFINING Co. Brit. 302,375, Aug. 15, 1927. A cell is described in which colloids and metal hydroxides are sepd. at the cathode and acid radicals of the metallic compds. migrate to the anode, thus reducing acidity of the solu in the cathode compartment and promoting further coagulation of the colloids there present.

## 29—LEATHER AND GLUE

ALLEN ROGERS

Report of German Leather Industry Research Institute, 1928. PAESSLER. *Gerber* 55, 69-71, 80-2(1929).—Results of analyses of tanning materials and accessories are given

H. B. MERRILL

Histological structure of skin and its relations to the quality of the finished leather. I. Histological structure of skin. MADGE KAYE. *J. Intern. Soc. Leather Trades Chem* 13, 73-87(1929).—The general histology of skin is discussed, and the fibers are considered in detail. Collagen, elastin and reticulin fibers are distinguished. Reticulin fibers, very fine and delicate in form, have hitherto been classed either as elastin or as collagen. They can be distinguished from collagen and elastin by means of staining reactions, acid and alkaline swelling and selective enzyme digestion. Reticulin fibers permeate the whole of the fibrous portion of the skin, forming a very delicate connecting and supporting tissue. Reticulin is very resistant to the action of acid and alkali, but is readily attacked by bacteria and is gradually attacked by  $Na_2S$ . Reticulin fibers are destroyed by putrefaction and ruptured by drying or by excessive swelling of the skin. It is necessary to break down the reticular structure in order to produce a leather at once full and supple, but once this is done the stock must be treated with care to avoid loose leather. Relation of structure and arrangement of fibers to quality of leather. *Ibid* 118-54.—Factors considered are (1) type of "weaving," (2) internal structure of bundles, (3) packing and (4) uniformity. These differ in different parts of the skin, are interrelated, and may be good or bad depending upon the kind of leather to be produced.

H. B. MERRILL

Preservation of hides with brine and salt. MADGE KAYE. *J. Soc. Chem. Ind.* 48, 141-87(1929).—Pieces of oxhide cut within 15 min. of the death of the animal were kept in the air for from 0 min. to 8 days, then samples of each were brined with solns. contg 10-33%  $NaCl$ , or salted with dry  $NaCl$ . Microscopic examn. of samples before brining showed that delay of even .5 hrs. before brining caused noticeable changes. Changes occurring up to 8 days included progressive destruction of cell nuclei; loosening and destruction of epidermis; shrinking and destruction of fat and sweat glands; contraction, shrinkage and destruction of erector pili muscles; breaking away of follicles from hairs, beginning at roots; collapse of blood vessels; breaking away of elastin fibers from other tissues (fibers themselves were apparently not altered); increasing shrinkage, sepn. into fibrils, and straightening of collagen fiber bundles. All these effects except damage to muscles and elastin fibers are visible after 11 hrs. Treatment with solns. contg. 23%  $NaCl$  or more is sufficient to arrest damage, when the temp.

is 22°, but at higher temps. 27% NaCl is the lowest effective concn. The influence of the common denaturants used in continental Europe was studied; the best results were obtained with NaHF<sub>2</sub> or Na<sub>2</sub>CO<sub>3</sub>; K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> does not seem to produce permanent stains on hide, but CuSO<sub>4</sub> sometimes does. Defects in hides and leather traceable to improper salting preservation include "marbled" grain, pipiness, thin grain, tender and loose leather, veininess and greasiness (due to excessive absorptivity for oil).

H. B. MERRILL.

**Action of sodium chloride on hide and animal tissues.** A. PONTE. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* 7, 97-119(1929).—The employment of NaCl in the tannery and for preservation of foods is discussed and the theory of its action given. The changes in vol. occurring in hides when immersed in pure NaCl solns. of different concns. were detd. experimentally. Including the results obtained in former studies the vol. of hide corresponding to 100 g. of dermic substance dried at 100° was 70 cc., that of hide dried in air (12% H<sub>2</sub>O), 85 cc., of partially dehydrated hide (59 and 64% H<sub>2</sub>O, resp.), 214 and 247 cc., resp.; of hide in the normal state (79.5% H<sub>2</sub>O), 450 cc. Treatment with 5.8% NaCl soln. caused the vol. to increase to 464 cc., while treatment with solns. contg. 11.7, 17.5 and 23.4%, resp., of NaCl soln. brought about a reduction of the vol. to 347, 221 and 194 cc., resp.

**Studies on the disinfection of anthrax-infected hides. II. The sodium sulfide method.** G. BROTZU. *Boll. soc. ital. biol. sper.* 4, 154-6(1929); cf. C. A. 22, 2289. Normal solns. of various inorg. salts were added to equal parts of N NaOH and Na<sub>2</sub>S and the mixt. was tested for germicidal activity on anthrax-infected hides and on filter paper satd. with a strain of anthrax of medium resistance. K<sub>2</sub>AsO<sub>4</sub> was the most effective in strengthening the germicidal power of NaOH and Na<sub>2</sub>S. Anthrax-infected hides were completely freed of spores when treated by this mixt. The results with filter paper were irregular.

PETER MASUCCI

**Some studies of the science and practice of bating.** GEO. D. McLAUGHLIN, JOHN H. HIGHBERGER, FRED O'FLAHERTY AND E. KENNETH MOORE. *J. Am. Leather Chem. Assoc.* 24, 339-78(1929).—In beamhouse procedure corium gains more wt. than whole skin at every stage. Elastin from ligamentum nuchae of steer and calf gained wt on treatment with satd. Ca(OH)<sub>2</sub> soln. and lost wt. after treatment with oropon. Elongation under pull of 500 g. decreased on liming and increased on bating. Loss of N of elastin showed only negligible amts dissolved in bating for 4 hrs., compared to amts dissolved in soak and lime. Involuntary muscle from uterus of calf lost 2% N in soak, 14.6% in lime and 2% in oropon bate (24 hrs.). These findings indicate that digestion of elastin and erector pili muscles is not an important function of bate. Swelling (H<sub>2</sub>O-imbibition) was detd. for whole skin, involuntary muscle and elastin after soak, after lime, after bate and after resoaking in H<sub>2</sub>O at 50°F. following bating. Bating was done for 1 or 2 hrs. with either oropon, lactic acid or NH<sub>4</sub>Cl. Involuntary muscle swelled more than other tissues after liming; the difference was decreased by bating but reappeared on cold-water treatment. The decrease brought about by bating and the subsequent increase was the same for purely chemical and for enzyme bate. Swelling of erector pili muscles accounts for roughening of goat skins observed when they are plunged into cold H<sub>2</sub>O after bating. It is deduced from photomicrographs that reticular tissue is dissolved during bating. S and N contents are tabulated for calf hair, hair and scurf, epidermis, upper 15% of skin, corium, whole skin, keratose and metaprotein from lime liquor. Of total N dissolved in the beamhouse, about 25% is dissolved in the soak, about 50% in the lime and the rest in the washes and bate. Total N removed from skin in washes and bate increases only slightly with time of bating, and total S removed in washes and bate does not increase at all with time of bating. Increased time of bating causes relatively more of each material to be removed in the bate and relatively less in the subsequent wash. Slightly more N is removed up to 3 hrs. by the active bate, and no more S is removed by the active than by the inactive bate. Removal of keratose is not an important function of the bate, since keratose is rich in S. N removed up to 3 hrs. is ascribed to digestion of coagulable dissolved protein. At 3 hrs., rate of digestion of N by active bate increases sharply; this is attributed to digestion of collagen. Rate of soln. of N and S in bating is independent of whether skin was soaked in pure H<sub>2</sub>O or in 10% NaCl. Total N dissolved in beamhouse is greater when skins are soaked in salt solns. **Conclusions.**—Principal functions of bating

are removal of sol. coagulable protein (inter-fibrillary substance), and reticular tissue.

H. B. MERRILL

**Contribution from the institute of tannery science. IV. G. GRASSER AND H. NAKANISHI. *J. Faculty Agr. Hokkaido Imp. Univ.* 23, 87-90(1929). 1. Tanning action of alcoholic tannin solutions.** Plates of dry gelatin (0.5 g.) were placed in solns. contg. 5 g. dry tanning material in 50 cc. EtOH for 3 days. The following materials were employed: oak gall tannin, oak wood ext., quebracho ext., Neradol D, quinone, HCOOH (40% aq. soln.). The m. p. of the gelatin plates and wt. of H<sub>2</sub>O absorbed on swelling in 0.1 N NaOH and HCl were detd. before and after treatment. These tests showed that HCOOH had marked tanning action (the m. p. was raised from about 35° to 94.5°), quinone a very slight, and the other materials no tanning action in EtOH soln. The tanning action of HCOOH is accounted for by the H<sub>2</sub>O introduced in the 40% soln. employed. In a duplicate series, in which the gelatin was allowed to imbibe H<sub>2</sub>O before being placed in the EtOH soln., HCOOH and quinone raised the m. p. to a value higher than 100°; the other materials showed no tanning properties even in the presence of the small quantity of H<sub>2</sub>O introduced with the gelatin. 2. **Tanning action of complex chromium salts.** *Ibid* 90-3.—Strips of skin were tanned in solns. of Na dioxalato-diaquo-chromate to which was added Na<sub>2</sub>CO<sub>3</sub> to produce basicities of 53%-98%. On boiling, all the leathers shrank 62-72% of their original lengths. 3. **Effect of inert substances on alkaline swelling.** *Ibid* 93-110.—When 2 g. of unharmed and delimed skin is treated with 50 cc. of 0.01 N alkali or alk. salt, the swelling produced (judged from increase in wt. of skin) increases in the following order: Na<sub>2</sub>HPO<sub>4</sub>, Ca(OH)<sub>2</sub>, Na<sub>2</sub>CO<sub>3</sub>, NaOH, Na<sub>2</sub>S. The latter produces the most rapid as well as the greatest eventual swelling. On addn. of increasing amts. of neutral salts, swelling first increases, then decreases. Sugars decrease swelling and alcs. increase it. 4. **Chemistry of chrome salts.** G. GRASSER AND K. HIROSE. *Ibid* 110-25—(a) **Basic Cr salts.**—Na<sub>2</sub>CO<sub>3</sub> was added to solns. of Cr alum up to the pptn. point. Pptn. occurred when the % basicity was about 66. It is stated that this basicity forms the boundary line between crystalloid and colloid Cr salts, and that therefore "max tanning intensity" should be exhibited by a salt of the empirical formula [Cr<sub>6</sub>(SO<sub>4</sub>)<sub>2</sub>(OH)<sub>12</sub>]<sub>2</sub>. Hypothetical structural formulas of this and similar hypothetical compds. are given. (b) **Influence of age and temp. on acidity of Cr and Fe salts.**—Acidity is measured by the vol. of Na<sub>2</sub>CO<sub>3</sub> soln. required to produce a permanent turbidity when added to 10 cc. of the Cr or Fe salt soln. ("pptn. figure"). 0.125 M soln. of CrCl<sub>3</sub>, Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> and Cr alum were employed. Upon heating to 15-100°, the pptn. figure of CrCl<sub>3</sub> is const. up to 60°, then declines; that of Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> increases from 15° to 60°, then declines; that of Cr alum falls from 15-100°. On standing at room temp. for 42 days, the pptn. figure of CrCl<sub>3</sub> does not change; those of Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> and Cr alum fall slightly. On boiling for periods of from 1 min. to 48 hrs., pptn. figures for CrCl<sub>3</sub> and Cr alum vary irregularly; that of Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> increases markedly. Fe salt employed were FeCl<sub>3</sub> and FeSO<sub>4</sub>·(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>. The pptn. figure of each salt soln. falls with increasing temp., but is unaltered by standing at room temp. On boiling, both solns. pptd. without addn. of alkali.

H. B. M.

**Qualitative analysis of tanning materials by means of ultra-violet light. V. KUBELKA AND V. NEMEC. *J. Intern. Soc. Leather Trades Chem* 13, 113 7(1929).—The fluorescence of tanning materials dissolved in (Et<sub>2</sub>O, AcOEt or EtOH) is stronger and more characteristic than in H<sub>2</sub>O. For Et<sub>2</sub>O or AcOEt, shake 20 cc. analytical tannin soln. with 10 cc. solvent for 5 min., sep. the ethereal layer and exam. under quartz light (1) soln. as prepd., (2) after acidification, (3) after making alk., (4) after drying on cotton wadding. For EtOH soln., ext. the dry tanning material with 50% EtOH and proceed as above. Fluorescence colors of 13 natural tanning materials, 13 syntans and sulfite-cellulose ext., are tabulated. *Specific reaction for gambier.* Add 5 cc. EtOH to 5 cc. aq. tannin soln., shake 1 min., and place under the lamp. In presence of gambier a gray-violet fluorescence is produced. Make alk. with NaOH, add 10 cc. petroleum ether, shake well, sep. petroleum ether layer, and exam. under the lamp. A brilliant pale green fluorescence is produced even in the presence of very small amounts of gambier.**

H. B. MERRILL

**Methods employed for the determination of the pH value of tan liquors and lime purrs. WINNIFRED BERTHA PLEASS. *J. Soc. Chem. Ind.* 48, 152-6T(1929).—Three methods are compared: (1) colorimetric (a), comparator, (b) "capillator;" (2) electro-etric methods involving the direct measurement of e. m. f. between a soln. contg. ions and standard electrode, (a) H electrode, (b) quinhydrone electrode; (3) electro-etric method depending upon e. m. f. between an exptl. liquor and buffer soln. sep'd. by glass membrane. The capillator is considered simpler and better than the compara-**

tor. In the capillator method the soln. under examn. is mixed with an equal vol. of a standard indicator soln. and drawn into a capillary, and the color compared with the color of a standard indicator soln. in a sealed capillary. Salt error is considered negligible. The color of the liquor interferes, but can be lessened by diln. and compensated for by introducing a special cell filled with a 2-fold diln. of the unknown soln. between the standard capillary tube and the eye. The capillator method is thought to be accurate to about 0.3  $p_H$  units. The H-electrode method gives satisfactory results, except in the presence of sulfides and sulfites. The quinhydrone electrode is of no use for  $p_H$  values greater than 8. The glass membrane cell gives satisfactory results for all types of tan liquors and lime liquors. Comparison of results obtained with capillator, H electrode, and so-called glass electrode for tan and lime liquors, to which were added varying amts. of  $Na_2S$  or  $Na_2SO_3$ , showed that the capillator checked the glass electrode for all concns. of  $Na_2S$  and  $Na_2SO_3$  in tan liquors; the H electrode checked the glass electrode in tan liquors when  $Na_2S \leq 0.0003\%$  and  $Na_2SO_3 \leq 0.05\%$ ; in lime liquors when  $Na_2S \leq 0.1\%$ . The capillator is not adapted to lime liquors because of the lack of suitable indicators. H. B. MERRILL

**Proposed official method of the I. S. L. T. C. for analysis of one-bath chrome liquors.** R. FARADAY INNES. *J. Intern. Soc. Leather Trades Chem.* 13, 111-2 (1929).—Cr is detd. by oxidation with  $H_2O_2$ . Decompn. of  $H_2O_2$  is catalyzed by Fe, or alternately by  $KMnO_4$ . In either case, soln. is filtered and Cr detd. with  $Na_2S_2O_3$  as usual. Ppt. of  $CaO_2$  sometimes forms in old liquors, but is removed by filtration. Acidity is detd. as usual, and  $p_H$  value electrometrically. H. B. MERRILL

**Notes on tannery laboratory equipment.** C. H. SPIERS. *J. Intern. Soc. Leather Trades Chem.* 13, 8-10 (1929).—S. suggests the use of stainless-steel balance pans which are said not to react with tan liquor, pipets of special sizes and other labor-saving devices. A simple comparator is described. H. B. MERRILL

**Some phenomena in vegetable tanning.** CESARE SCHIAPARELLI AND GIOVANNI BUSSINO. *Cuir tech.* 18, 147-51 (1929).—See C. A. 23, 1301. J. G. NIEDERCORN

**The wattle-bark industry.** ANON. *Bull. Imp. Inst.* 27, 169-83 (1929).—An account of the attempts which have been made to utilize the by-products of the wattle bark industry, with a discussion of the bearing of the question on the future of the wattle-bark industry in countries of the British Empire. A. PAPINEAU-COUTURE

**Tanniferous barks of Madagascar.** I. MIMOSA. A. DEFORGE, J. MAHIEU AND F. HEIM DE BALSAC. *Halle aux cuirs* 1929, 49-57, 84-92; cf. C. A. 23, 3592. Advantages of mimosa as a source of tannin to replace vanishing European supplies are (1) rapid growth (bark harvested at 8-12 yrs.), (2) high tannin content, (3) high tannin-non-tannin ratio in ext., (4) ease of extn., and (5) low fermentability of ext. Tanning properties are so similar to those of chesnut that direct substitution is often possible. The red color imparted to the leather can be avoided by admixt. with suitable materials, e. g., with myrobalams. Analyses of 5 samples are given. III. "Rotra" (*Eugenia* sp.). *Ibid* 175-83.—Analysis of the bark showed:  $H_2O$  13.7%, tannin 12.6%, non-tannin 12.2%, insol. matter 61.2%; the ext. is very turbid; reducing sugars are present only in traces; it contains both catechol and pyrogallol tannin. The high non-tannin content indicates that the material is little astringent, and highly fermentable. These properties may make it valuable as one constituent of a tanning liquor. H. B. M

**The synthetic tannins in chrome tanning.** ENRICO SIMONCINI. *Boll. ufficiale staz. sper. ind. pelli mat. concianti, Suppl. tec.* 4, 51-6, 79-84 (1929).—S. distinguishes between "mild" and "strong" synthetic tannins. The "strong" synthetic tannins, among which figure the cresol derivs. (I), are of instantaneous action, while the "mild" synthetic tannins, whose type is represented by the naphthol derivs. (II), have a slow action. With I the intensity of the reaction between synthetic tannin and hide diminishes with decreasing acidity of the bath, while with II a change in the degree of acidity is of little influence on the velocity of the reaction. When samples of cow hide were given a treatment with II before the chroming, the quality of the resulting leather improved considerably. With I the results were less favorable. The concn. of the syntans influenced the amt. of  $Cr_2O_3$  absorbed during chroming, the absorbed  $Cr_2O_3$  decreasing with increased concn. of the syntans. G. SCHWACH

**Formaldehyde tannage.** B. ZIROULSKY. *Halle aux cuirs* 1929, 163-70.—Hide powder samples were digested with solns. of  $HCOOH$  under varying conditions of time, concn., and acidity or alkali. The decrease in  $HCOOH$  concn. of the soln. during the expt. was assumed to be a measure of the  $HCOOH$  taken up by the hide. Results

indicated that equil. is established in about 5 hrs., and that absorption increases with concn. of  $\text{HCOOH}$  and with concn. of  $\text{Na}_2\text{CO}_3$ , but decreases with concn. of  $\text{H}_2\text{SO}_4$ .

H. B. MERRILL

**Effect of nitrate oxygen upon tannery effluent.** EDWIN R. THEIS AND JOHN A. LUTZ. *Ind. Eng. Chem.* 21, 763-6(1929).—Soak-water from steer hides was treated with varying amts. of  $\text{NaNO}_3$  for varying periods, and amt. of reduction, vol. and compn. of gas evolved, and pressure produced was measured. Large vols. of  $\text{N}_2$ , with some  $\text{CO}_2$ , and a little  $\text{O}_2$  are produced; the %  $\text{N}_2$  in the gas increases with time.

**Colloid chemistry in the leather industry.** GEORGES GÉNIN. *Halle aux cuirs* 1929, 44-7, 71-5, 115-8, 139-43, 184-8.—A review.

H. B. MERRILL

**Effect of heat on wetted vegetable-tanned leather.** III. W. J. CHATER. *J. Intern. Soc. Leather Trades Chem.* 13, 24-36(1929); cf. *C. A.* 23, 2596.—Strips of leather or pelt were variously treated, and their expansion and contraction curves upon heating in  $\text{H}_2\text{O}$  were detd. by the method previously described. The effect of borax stripping of vegetable leather is to increase the expansion up to shrinkage temp. and to lower the temp. of shrinkage. The effect becomes more marked the longer the leather is exposed to the borax. The effect of increasing the time that calf pelt is limed in satd.  $\text{Ca(OH)}_2$  soln. is to decrease the expansion up to shrinkage temp., and to lower the temp. of shrinkage. When strips of calf pelt are soaked in buffer solns. of various  $p_{\text{H}}$  values, the temp. of shrinkage is a max. when the soaking is done at  $p_{\text{H}}$  10, and decreases when  $p_{\text{H}}$  of the soak is either increased or decreased.

H. B. MERRILL

**Some present-day problems with special reference to measurement of properties of sole leather and effect of sulfuric acid.** D. BURTON. *J. Intern. Soc. Leather Trades Chem.* 13, 178-91(1929).—Recent work on the following topics is discussed: (1) measurement of properties of sole leather; (2) significance of sp. gr. of leather, (3) degree of tannage, (4)  $\text{H}_2\text{SO}_4$  in leather, (5) influence of method and degree of liming on yield of sole leather, (6) method for sterilizing anthrax-infected hides, (7) methods for analyzing bate liquors, (8) methods of preventing deposits from myrobalsams ext., (9) relation between constants of fats and oils and the properties they impart to leather, (10) difference between tanning liquors made from exts. and by leaching.

H. B. MERRILL

**Sulfuric acid in vegetable-tanned leather.** R. FARADAY INNES. *J. Soc. Chem. Ind.* 48, 149-52T(1929); cf. *C. A.* 22, 4003.—Hide was tanned in a vegetable tan liquor until partly struck through; it was then suspended in dil.  $\text{H}_2\text{SO}_4$  ( $p_{\text{H}}$  1.6) and tannage was completed in a series of vegetable-tan liquors. After acid treatment, before further tanning, the untanned portions of the skin contained more acid than the tanned portions, and as tanning progressed the acid content of the leather became less and less, showing that tannin hinders the taking up of  $\text{H}_2\text{SO}_4$  by collagen, and displaces that previously taken up. When  $\text{H}_2\text{SO}_4$  is added to solns. of chesnut, myrobalsams or mimosa, the liquor manifests a considerable neutralizing power for acid, sometimes in excess of that corresponding to the alk. of the liquor ash. Collagen sulfate (*i. e.*, skin contg. about 4%  $\text{H}_2\text{SO}_4$ ) is not damaged on storage up to 7 years, and on heating is not decompd. up to  $180^\circ$ . Vegetable-tanned leather contg. only half as much acid is decompd. on heating to  $140^\circ$ . The difference is that in pelt the acid is combined, while in leather it is free or readily hydrolyzable. The kind of tannin seems to be a factor in the decompn. of leather by acid. Conclusion: Treatment of skins with  $\text{H}_2\text{SO}_4$  before or during tanning does not damage the resulting leather; treatment after tanning may do so.

H. B. MERRILL

**Acidity control of chrome leather.** J. S. MUDD AND P. L. PEBODY. *J. Intern. Soc. Leather Trades Chem.* 13, 205-14(1929).—Samples of chrome leather were neutralized with varying amts. of borax and fat-liquored with sulfonated oil. The fat content of the leather decreased with increasing neutralization up to 2 parts borax per 100 leather; on further increasing the proportion of borax, % fat absorbed increased slightly. Samples of defatted leathers were boiled with  $\text{H}_2\text{O}$  for varying periods, and  $p_{\text{H}}$  value and titratable acid of ext. detd. Equil. is established in 45 min. or less. The  $p_{\text{H}}$  value of ext. increases with increasing degree of neutralization, and is characteristic of the acidity of the leather. Ionogenic  $\text{SO}_4$  detd. by extn. with 4% aq. pyridine, decreases with increasing neutralization, but complexly bound  $\text{SO}_4$  detd. by extg. with  $\text{NaOH}$  after pyridine extn., is not much diminished until excess of borax is very large. Basicity of leather increases with increasing neutralization, but basicity of Cr complex is not altered unless borax is used in large excess.  $\text{NaOH}$  and  $\text{Na}_2\text{CO}_3$  have the same effect as equiv. amts. of borax, but "sodium phosphate" (basicity not stated)

has a smaller displacing effect on sulfate than the other neutralizing agents used.

**Moisture in leather.** H. BRADLEY, A. T. MCKAY AND B. WORSWICK. *J. Intern. Soc. Leather Trades Chem.* 13, 10-24, 87-106(1929).—In the equation  $a = (\alpha p T / 273x) / (1 - \beta p T / 273x)$ ,  $a$  = amt.  $H_2O$  vapor taken up,  $p$  = % relative humidity,  $T$  = °K,  $x$  = 2 or a multiple of 2, and  $\alpha$  and  $\beta$  are consts. with respect to  $a$  and  $p$ , but vary with  $T$ . The equation agrees well with the exptly. detd. curves for various leathers over "quite a considerable range of humidity." Values of  $\alpha$  and  $\beta$  are given for 7 kinds of leather as well as for wood, cotton and wool.  $\beta$  is nearly constant for all these materials, and hence  $\alpha$  is a measure of absorptive power. Values for  $\alpha$  varied from 1.5 for a sole leather to 0.5 for a curried vegetable split. In general,  $\alpha$  decreases with increasing fat content. At high relative humidities leather gives up and takes on water at approx. the same rate, but at low relative humidities it gives up water very slowly and takes it on again very rapidly. No difference was observed in rate of diffusion of water through sole leather from grain side towards flesh side and *vice versa*. Values of  $H_2O$  vapor cond. const. are tabulated for 20 leathers. For the absorption of liquid  $H_2O$  is derived the equation  $Q/Q_m = 1 - (8/\pi^2)(e^{-\pi^2 kt/4a^2} + 1/9e^{-\pi^2 9kt/4a^2} + \dots)$ , where  $Q$  = quantity of water in leather at time  $t$  and  $Q_m$  = quantity at satn. This equation fits exptly. detd. absorption-time curves for leather remarkably well, proving that absorption may be regarded as a pure diffusion process.  $Q_m$  is not so important a criterion of water-proofness as the time,  $\tau$ , required to produce practically complete satn. When  $Q(\text{initial}) = 0$ ,  $\tau = (\text{Thickness})^2 / \text{Diffusivity}$ . Values for diffusion const. and for  $\tau$  are given for numerous leathers.

**Determination of fat in leather.** FINI G. A. ENNA. *J. Intern. Soc. Leather Trades Chem.* 13, 37-8(1929).—E. advocates drying the leather in an atm. of  $CO_2$  prior to extn.

**The manufacture of glazed kid.** GEORGES POUTZKARNIK. *Cuir tech.* 18, 73-7, 94-101(1929).—A description.

Chlorination of waters for industrial use [especially tannery water] (AUERBACH) 14. Methods and applications of photomicrography (WIGHTMAN, TRIVELLI) 5. The reduction of dichromate to basic chromic salts (GRASSER, NAGAHAMA) 6. Tanning of fishing nets (DURANT) 25. By-products in manufacturing abietic essential oils. Abietic extracts [for tanning industry] (BOBROV) 27. Sulfonated oils [for leather industry] (Fr. pat. 657,220) 25.

**Removal of wool from skins without attacking the wool or hair.** SOCIÉTÉ INDUSTRIELLE DES APPLICATIONS CHIMIQUES "INDAC." Belg. 355,180, Nov. 30, 1928. The skins are immersed in an unhairing bath through which is passed air or an inert gas to prevent packing of the skins and effect circulation of the bath. Cf. C. A. 23, 2066.

**Rapid tanning.** P. PAWLOWITSCH. Brit. 302,408, Sept. 20, 1927. The hide is first treated with a vegetable tanning ext. in soln. of a  $pH$  of 6 to 12 and then with a soln. of  $pH$  of 2 to 5 (suitably at a temp. of 30-37°). The concn. is varied somewhat according to the nature of the tanning material which may be derived from quebracho, chestnut oak, pine bark, etc., and in the second stage acids or acid synthetic tanning substance may be added gradually.

**Tanning agents.** MICHAEL MELAMID. Ger. 478,272, June 17, 1923. Humic acid or other humous substance is heated with aq.  $HCl$  or  $H_2SO_4$  and then sulfonated with fuming  $H_2SO_4$ .

**Products for effecting emulsifications and for use in tanning, foaming, etc.** I. G. FARBENIND. A.-G. Brit. 302,666, Dec. 19, 1927. Substances such as condensation

highly concd. solns. of sulfonic acids of aromatic or hydroaromatic or condensation products of such acids. The products may be used in tanning, as foaming or emulsifying agents, in dyeing, fungicides, insecticides, etc. Several examples with details of procedure are given.

**Tanning and wetting agents, etc.** I. G. FARBENIND. A.-G. Brit. 302,938, Dec. 23, 1927. In a modification of the process described in Brit. 302,666 (preceding abstract) there are employed, instead of the aromatic compds. with OH in the nucleus or condensation products of such compds., mixts. of such compds. with substances of high mol. wt. such as resins, oils, waxes, fats or fatty acids. Several examples with details are given.

**Diastasic products.** CHARLES J. M. M. LE PETIT. Fr. 656,770, Nov. 16, 1927. Plasmolyzing salts are added to mold cultures to liberate rapidly the diastases. A dehydrating agent may also be added to obtain a dry powder. An example is given in which *Aspergillus oryzae* is mixed with  $\text{Na}_2\text{SO}_4$  and a little  $\text{NaHCO}_3$  and  $\text{H}_3\text{BO}_3$ . The products are used in tanning.

**Coating leather, hides, skins, etc.** J. R. C. JORGENSEN. Brit. 301,554, July 6, 1927. A highly viscous or highly concd. and easily solidifying cellulose ester or ether soln. such as a soln. of cellulose acetate 12 in acetone 79 parts is applied to the material in regulated thickness to give the final desired thickness of coating. Various details and modifications are given.

**Treating leather for shoes with solutions of resin and nitrocellulose.** C. BERGER. Brit. 302,627, Sept. 15, 1927. Details of applying coatings for patent leather shoes are described.

**Stiffening insole leather with sodium silicate solution.** W. E. IANE. U. S. 1,720,223, July 9. The tanned leather is dipped in a dil. aq. soln. of the silicate.

**"Artificial leather" (coated fabric).** W. PLINATUS (to Compagnie française d'exploitation des procédés Plinatus). Brit. 301,759, Dec. 3, 1927. An app. is described for uniting sheets of textile fabric or paper with thin rolled sheets which may be formed of cellulose esters or ethers together with softening and gelatinizing agents, etc. Various details of manuf. are given.

### 30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

**Professional saturnism in the rubber industry.** F. HEIM DE BALSAC, F. AGASSE-LAFONT AND A. FEIL. *Chimie & industrie Special No.*, 739(Feb., 1929).—Investigations carried out in 2 plants showed that danger of saturnism exists in the rubber industry, but that it can be prevented by the usual prophylactic measures. A. P.-C.

**Plasticity determinations in crude rubber. VII. Relation between structure and plasticity of rubber prepared in different ways.** O. DE VRIES AND N. BEUMÉE-NIEUWLAND. *Arch. Rubbercultuur* 13, 283-353(1929). (In shorter form in English 354-70.)—Numerous papers in recent years on the relation between the structure of raw rubber and its plasticity have contained interesting hypotheses dealing with the structure of the globules, but have not been supported by exptl. data. On the other hand the investigations of de V. and his collaborators have dealt with the influence of the non-rubber substances and with different methods of coagulation and prepn. These latter investigations have been recently reviewed (cf. *C. A.* 22, 2077; *India Rubber J.* 75, 511(1928)), while the present paper is also a crit. review and discussion in amplified form, with tables of quant. data, and with numerous references. This long discussion leads to certain general conclusions. The sol. serum substances have a marked effect on plasticity, rubber with a high content of serum substances becoming harder during storage, whereas rubber with a low content sometimes becomes softer on storage, and when creped is softer even when fresh. The substances which are pptd. from the serum during coagulation (the network of proteins) have little influence on plasticity. Centrifuging and washing the cream gives a plastic rubber which has no tendency to become tacky or to deteriorate on storage, so that this seems one of the few practical ways of obtaining a more plastic raw rubber. Swelling with org. solvents, such as  $\text{C}_6\text{H}_6$  and  $\text{PhMe}$ , which causes fusion of the rubber globules and union into large units, has an unexpectedly little influence on plasticity, not only when latex is treated with the solvent but also when rubber is dissolved in the solvent and recovered by evapn. This phenomenon is worthy of further study because of its importance in explaining the relation between the structure of rubber and its plasticity. C. C. DAVIS

**Importance of temperature and humidity control in rubber testing. II. Resistance to abrasion.** W. A. GIBBONS, et al. *Ind. Eng. Chem., Anal. Ed.*, 1, 174-80(1929); cf. Partenheimer, *C. A.* 22, 511; 23, 1306.—The earlier investigation was continued with a study of the influence of the temp. and of the relative humidity between mixing and curing on the resistance to abrasion. Four different types of mixts. were tested on two different abrasion machines. The results, which are recorded in tabular and graphical form, and are discussed in detail, admit of certain general conclusions. In detg. resistance to abrasion, the temp. should be controlled within  $1^\circ$  to avoid significant errors from this cause. The relative humidity at which either an uncured or cured mixt. is maintained need not be considered in comparative tests, though when the relative

humidity varies over an abnormally great range, greater precision may be attained by conditioning uncured and cured mixts. The temp. at which vulcanizates are ordinarily stored has little effect on their resistance to abrasion. C. C. DAVIS

**The influence of the temperature on the strength of fabrics.** L. STOLL. *Gummi-Ztg.* 43, 2218-21(1929).—The results are of importance in rubber manuf. because of the heating which fabrics undergo during vulcanization. Samples of a fabric cord were heated at 60°, 80°, 100°, 110°, 140°, 150°, 170°, 200° and 220° for 0.25, 2, 4, 6, 8 and 15 hrs. and the elongation and breaking strength before and after the heating detd. The exptl. results, which are recorded in tables and graphs, admit of certain general conclusions. The higher the temp. and the longer the time of heating the greater is the loss in breaking strength and in elongation. Even after 15 min. of heating, there was a considerable loss of strength, viz., around 4% at 100°, 12% at 150° and 20% at 200°. Up to 110° the loss in elongation and strength may be considered relatively small, while at 140-150° the loss of strength becomes considerable, e. g., around 15% after 2 hrs. C. C. DAVIS

**The action of sulfammonium on rubber.** R. FRIC. *Chimie & industrie Special No.*, 538-9(Feb., 1929).—NH<sub>3</sub> was condensed on S at -80°, a strip of rubber was introduced into the tube, which was then sealed; after 48 hrs. the tip of the tube was broken and during the rapid evapn. of NH<sub>3</sub> the rubber gradually swelled till it practically filled the tube, its surface became coated with pulverulent S, and as the NH<sub>3</sub> escaped by diffusion it gradually regained approx. its original size, though still retaining a notable deformation. The feel, detn. of combined S, swelling in benzine and mech. strength tests indicated it had undergone at least a slight partial vulcanization, which F. attributes to the action of the nascent S liberated in the decompn. of sulfammonium

A. PAPINEAU-COUTURE

**The influence of sunlight on the color of rubber mixtures.** H. RIMPEL AND P. HERRMANN. *Gummi-Ztg.* 43, 2270(1929).—The exptl. facts described by DRIES and Naunton (C. A. 23, 2068) were also discovered by R. and H. and are incorporated in a patent, in which they are utilized for the production of pictures or designs on rubber goods (cf. German Patent 448,972). Evidence is given to prove that D. and N. are incorrect in believing that the initial effect of the irradiation is a surface vulcanization and that the discoloration is a result of over-vulcanization on the surface of the vulcanizate. Designs are formed on rubber not only by heating or by vulcanization after exposure, but also by treatment with strong reducing agents, as with light-sensitive AgBr-gelatin. If the reducing agent is mixed into the rubber, it is possible to form designs or pictures directly by exposure to light. When 4 mixts., each contg. rubber, lithopone and ZnO, and the 1st also S, the 2nd accelerator, the 3rd S and accelerator, and the 4th no addn., were exposed to sunlight for 3 hrs. and were then heated at 143° for 30 min., the 1st and 4th mixts. remained unchanged, whereas the 2nd and 3rd mixts. became discolored to an equal extent. This indicates that such discoloration depends only upon the accelerator and that it has no direct relation to the state of cure. The accelerator thus behaves like the reducing agents described in the patent of R. and H. (*loc. cit.*), and the phenomenon is similar to that of a AgBr photographic plate. C. C. DAVIS

**Colloidchemical changes in rubber and fatty oils.** LASZLO AUER. *Trans. Inst. Rubber Ind.* 4, 499-520(1929).—A crit. review and discussion of present knowledge, with certain new points of view and new data. From a colloidal point of view, raw rubber may be regarded as a jelly,  $\beta$ -rubber being the gel skeleton and  $\alpha$ -rubber the dispersion medium.  $\beta$ -Rubber therefore corresponds to metastyrene and  $\alpha$ -rubber to liquid styrene.  $\beta$ -Rubber is probably only a more concd. soln. of the disperse phase itself, whereas  $\alpha$ -rubber is more concd. with respect to the dispersion medium of the jelly than is  $\beta$ -rubber, but it is not the dispersion medium itself. In expts by Pummerer (cf. C. A. 22, 885, 4873) a better agent than Et<sub>2</sub>O could not be found for their sepn., and so in the expts. of P. probably the only result was the concn. of one of the two phases of the jelly, the pure phase not being isolated at all. X-ray investigations agree with this (cf. Bary and Hauser, C. A. 22, 4005), diagrams of frozen rubber indicating an increase in  $\beta$ -rubber at the expense of  $\alpha$ -rubber. That coagulating agents aggregate rubber and solvents disaggregate it is supported by unpublished expts. of Stamberger, who has found that when org. solvents, e. g., CCl<sub>4</sub> or Et<sub>2</sub>O, are added to latex, and the water and solvent are then evapd., the film has not its usual solid character but is a very sticky paste. After a few days this stickiness disappears and the film acquires a normal condition. In this case the disaggregating agent probably retards the aggregation by air. A discussion of the drying of fatty oils and the extensive expts. of A. in this field, which led to the gas coagulation theory of drying.

(cf. C. A. 20, 3827; 21, 3475, 3789; 22, 1695; 23, 2089) led to the conclusion that the coagulation of latex on exposure to air is caused by the coagulating action of O. In prep. Para rubber, the gases in the smoke cause coagulation and aggregation, and the smoking process for smoked sheets involves a similar action. Rubber jelly has a smaller adsorptive power toward coagulating gases than the jelly of fatty oil films, hence the better aging of rubber. Rubber may be considered as a jelly composed of 2 phys. different phases of the hydrocarbon, the structure thus being like a gelatin hydrogel, plasticizing of rubber being like the mech. working of other jellies. Ions act as coagulants, and in gas coagulation gaseous ions are the active agent. Ultra-violet rays ionize gases and their action on fatty oils may be due to the ionization of dissolved O. Just below the b. p. of an oil the gas is evolved and the friction may change the gas electrically and so alter the colloidal structure of the system. In expts. on the *bodying of oils in vacuo*, large proportions (12–61% of the total acids obtained by hydrolysis) of acids insol. in petr. ether were formed, whereas before heating the proportion was small. This shows that the change from sol. to insol. acids is not a result of oxidation. The *mastication of rubber* may be explained by the 2-phase theory, but possibly gas peptization assists the mech. working, *i. e.*, the latter may cause gas peptization. The jelly contains adsorbed O which may be ionized by the friction. This agrees well with facts observed by Fry and Porritt (C. A. 22, 4870). Gases other than O can also cause peptization, but longer times are required (cf. Pummerer and Pahl, C. A. 22, 885). When rubber mixts. contg. considerable C black are stored before curing, the plasticity disappears and the mixt. acquires some of the properties of vulcanized rubber. When sep. layers are plied and cured under pressure the layers do not unite because a thin film on each surface is formed as a result of coagulation by adsorbed gases. The impossibility of extg. all S from vulcanized rubber does not necessarily signify a chem. combination. Removal of an adsorbed substance can be accomplished by (1) a substance which is more readily adsorbed by the adsorbing product than is the previously adsorbed substance (S), or (2) a solvent with a higher affinity for the adsorbed substance (S) than has the isocolloidal rubber or fatty oil. In each the agent must come into intimate contact with the adsorbed substance (S). S is enclosed in an aggregated system and the agent must also be a disaggregating agent. Therefore so-called combined S has not been removed except by such agents as  $\text{PhNH}_2 + \text{K}$  and by concd. HCl. Moreover, the adsorptive power of some systems is stoichiometrical, so even if an apparent limiting value of "combined" S has been found by most investigators (cf., however, Stevens, C. A. 23, 3596) it may signify merely a satn. of the adsorptive power. Bacon (cf. C. A. 22, 3804) did not necessarily wet the aggregated rubber with his desulfurizing agents. His fractional peptization expts. are difficult to reconcile with the chem. combination theory, and finally his limit of 0.5% combined S represents the threshold value of S adsorbed during the aggregation of rubber contg. an accelerator. A discussion of the two most satisfactory theories of *vulcanization*, *viz.*, the S coagulation or aggregation theory and the chem. theory (cf. Stevens, C. A. 22, 1703), points to the former as the more probable, with the accelerator playing the part of a sensitizer of coagulation by S, like the sensitizing action of Co linoleate on  $\text{HCO}_2\text{H}$  in the coagulation of fatty oils (cf. A., C. A. 21, 3789). When rubber is heated for a long time *in vacuo* at  $250^\circ$  it fuses to a viscous liquid, which on cooling does not revert to the original condition. The loss of wt. is only about 1% and no chem. decompn. can be detected. This *disaggregated rubber* resembles viscous heat-bodied stand oils, and can be vulcanized to products similar to the latter. Both this aggregated rubber and vulcanized rubber have corresponding types in fatty oil derivs., and the new solidified oil derivs. contg. electrolytes are the initial attempts to obtain *oil products resembling raw rubber*. In vulcanized form, these solidified oils have properties more nearly like rubber than any previously known oil product. Data show the *tensile strengths and elongations of rubber mixts. contg. vulcanized solidified oils* compared with those of the corresponding mixts. contg. ordinary vulcanized oils (factice). *Vulcanized solidified oils* are excellent ingredients; *e. g.*, when 50 parts are added to 100 parts of rubber, the vulcanizates have tensile strengths as high as, or even higher than, the corresponding vulcanizates contg. no such addn. of oil product, in contrast to ordinary vulcanized oils, which greatly lower the tensile strength of vulcanized rubber. The jelly system of solidified fatty oils can be further aggregated. S aggregates solidified fatty oils as it does rubber and raw oils. The solidified oils require less S than raw oils and in *varnishes* they require less O than raw oils. Accordingly *varnishes* contg. solidified oils dry more rapidly than the corresponding *varnishes* contg. raw oils, with correspondingly smaller adsorption of O. The latter fact explains the better aging of solidified oils. When

electrolytes are milled into raw rubber and the mixts. are then heated, products resembling the thermoplastic rubber products of Fisher (cf. C. A. 22, 887) are obtained. The latter were regarded as simply isomerization products, and the fact was overlooked that they were polydisperse systems in which the presence of the reagents or their decomposition reagents are necessary to the resulting properties. The excess reagent used by F. can be washed out, leaving the essential adsorbed part. The case is therefore analogous to the vulcanization of rubber with S partly extractable by acetone. The reactions of F. are also analogous to the action of electrolytes on fatty oils, in each case the dispersed phase being increased. The white powders pptd. by acetone from solns. of thermoplastic rubber products are probably the gel skeletons of the original jellies. Both with thermoplastic rubber products and with solidified oils, the aggregating action of the reagents is more limited than that of S or of gases, and both products may be further aggregated by S or by gases. The increased solv. of thermoplastic rubber products in org. solvents corresponds to the property of solidified oils of being readily emulsified in water. This probably does not depend upon a lower degree of aggregation of the jelly, but because the adsorbed reagent has a higher affinity for the solvent than for the jelly in which it is adsorbed. The solvents may, however, be disaggregating agents.

C. C. DAVIS

**Preparation and properties of aqueous rubber dispersions.** H. L. TRUMBULL, *Colloid Symposium Monograph* 6, 215-24 (1928).—Aq. dispersions of rubber can be obtained by masticating rubber or reclaim with protective colloids like glue, Na resinate, gum arabic, gluten, Na alginate blood albumin and casein (see U. S. P. 1,498,581). Such dispersions differ from latex in being free from pear-shaped particles, giving a dried film different in texture, tackiness and strength and being under control of the maker.

JEROME ALEXANDER

**The reduction of rubber stress-strain determination.** W. B. WIEGAND AND H. A. BRAENDLE, *Ind. Eng. Chem., Anal. Ed.* 1, 113 7 (1929).—The aim of the work was to find a means of eliminating the personal equation in interpreting stress-strain data. Reduction of 95 tests of an inner tube by statistical methods showed that the stress-strain data did not obey strictly the law of accidental error, the skew being neg. for the values at rupture and pos. at intermediate points. The true values are not therefore the arithmetic means but the modes, which in every case differed from the arithmetic means to an extent greatly exceeding the probable error of such means. By using these true values and dividing the 95 tests into groups of 5, these groups were weighted by 4 empirical methods and the results compared with the modal values. The method of choosing the highest 3 elongations out of 5, with the corresponding tensile strengths, approached most closely the modal values. This method is accordingly suggested as a starting point for a *standardized method of interpreting tests of rubber*. The work is in part a confirmation of expts. on the same subject by Fric (cf. C. A. 23, 4098).

C. C. DAVIS

**The use of a group of performance tests for evaluating rubber compounds that must withstand repeated compression.** HARLAN A. DEPEW AND E. G. SNYDER, *Proc. Am. Soc. Testing Materials* 1929 (preprint) No. 87, 11 pp.—Specifically the present paper gives data on the comparative resistance to abrasion and to pounding of 2 solid tires cured with different proportions of S. The underlying object is, however, to show that by a properly chosen set of lab. tests it is possible to judge the performance of rubber products in actual service. It may be necessary to include with the standard tests an addnl. test which is specially adapted to the particular product which is being developed. The solid tires, which serve as an example, were tested for tensile strength and ultimate elongation, for their hardness and for their resistance to tear, to abrasion and to pounding at different cures. They were also aged in a Geer oven to correlate the phys. properties mentioned above with the uniformity of cure and state of cur at different points in the tires. In the pounding test which is described and illustrated, the samples are subjected to very rapid impacts of high force, and the increases in temp. ascertained. The comparative tests of the 2 tires indicate that a low proportion of S minimizes variability of cure, that the proportion of S does not affect the uniformity of cure throughout the tire when sufficiently long cures are used, and that a high S content tends to low temps. in the tire in service.

C. C. DAVIS

**Rubber equipment for the chemical industry.** ANON. *Ind. Chemist* 5, 229-30 (1929).—An illustrated description of mfg. operations at the plant of Macinlop, Ltd (Manchester, England), including rubber-lined tanks, rubber-covered rolls for the paper, bleaching and dye industries, rubber hose, acid valves, acid-proof hose, rubber-lined pumps, fans and ball mills and conveyor belting, with the lab. control of the various processes.

C. C. DAVIS

**Instrument for reading the hardness or plasticity of rubber optically.** R. FRIC. *Caoutchouc & Industrie Special No.*, 536-7 (Feb., 1929).—The hardness of vulcanized rubber is detd. by placing on the rubber a ball of given diameter, attached to a vertical rod which in turn is connected to a balanced lever arm, and then weighting the end of the arm as required. The deflection of the lever (which depends on the depth to which the ball has penetrated into the rubber) is read by means of an optical device that greatly magnifies the displacement. To det. the plasticity of soft rubber, the same device is used to det. the rate of penetration of a cylinder of given diam. A. P.-C.

**French rubber sponges.** H. DE POIX AND F. DE POIX. *India Rubber World* 80, No. 5, 69-70 (1929).—A general description of present developments, with typical formulas. C. C. DAVIS

**Who was the first to utilize rubber for erasing? A needed correction.** MAX SPETER. *Gummi-Ztg.* 43, 2270-1 (1929).—Historical. Original references are cited to show that neither Priestley nor Magchaens was the originator of the idea of using rubber for erasing pencil marks. The credit should go to Nairne, a maker of mathematical instruments of London, who devised the eraser before 1770. C. C. DAVIS

**The rational use of scrap and reclaimed rubber.** H. BAUFARON. *Rev. gén. caoutchouc* 6, No. 52, 14 (1929).—Four formulas are suggested for molded products contg. scrap and reclaims. C. C. DAVIS

**An inquiry into the use of reclaimed rubber.** WALTER HUTCHINSON. *Déchets et régénères* 1, No. 1, 5 (1929).—The first of a series of articles to deal with the relative value of reclaimed and new rubber, the future of reclaimed rubber and the desirable properties of reclaimed rubber, and to give representative mixts. in which reclaimed rubber is of special advantage. These points are covered briefly. C. D. DAVIS

**Aging of rubber.** B. V. BIZOV. *Zhur. Prikladnoi Khim* 1, 6-11 (1928).—Soft gray rubber was cured in steam at 35 lb. per sq. in. for 10-60 min. and then aged at 70° for 24-96 hrs. The modulus of elasticity, the hysteresis, the product of these 2 quantities (or the "working capacity") and the swelling in AcOAm were detd. for individual samples and served to judge the degree of aging. The results obtained by these different methods were often contradictory. Properly vulcanized rubber undergoes smaller changes on aging than undercured rubber. The changes are probably due to a continuation of the vulcanizing process at the elevated temp. used in artificial aging tests. Artificial aging produces changes in rubber which are different from those observed in natural aging, and new accelerated testing methods must be developed which do not require an elevated temp. V. KALICHEVSKY

**Laboratory apparatus for studying the aging and the vulcanization of rubber.** R. FRIC. *Rev. gén. caoutchouc* 6, No. 52, 9-10 (1929); cf. C. A. 22, 4876.—An app. for the O-bomb aging test and an app. for vulcanizing lab. samples are described and illustrated. The chief feature is the manner of heating, utilizing induced (Foucault) currents with the attendant hysteresis effects, the principle being the same as the Ribaud high-frequency method of heating furnaces. The cost of operation is economical and a sufficiently precise control of temp. is claimed. C. C. DAVIS

**The outlook for synthetic rubber.** OSCAR L. BRAUER. *J. Chem. Education* 6, 1286-92 (1929). E. H.

**Organic accelerators of vulcanization.** HAN TANAKA AND YOSHIYUKI HARA. *Repts. Imp. Ind. Research Inst. Osaka Japan* 10, No. 1, 29 pp. (1929).—To make a comparative study of org. accelerators of vulcanization the authors tested the following: PhNISCNlPh (I), PhN:C(NHPh)<sub>2</sub> (II), *p*-NOC<sub>6</sub>H<sub>4</sub>NMe<sub>2</sub> (III), aldehyde-ammonia (IV), *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> (V), (CH<sub>2</sub>)<sub>6</sub>N<sub>4</sub> (VI), HN:C(NHPh)<sub>2</sub> (VII) and C<sub>8</sub>H<sub>10</sub>NCSSH.C<sub>6</sub>H<sub>5</sub>N (VIII). The accelerator was mixed in the proportions of 0.25, 0.5, 0.75, 1.0, 2.0, 3.0, 4.0 and 5.0 per 100 of rubber mixt. The accelerating powers were in the order: VIII (0.25-0.5) (the figure indicates the amt. of accelerator used per 100 rubber mixt.), III (0.25-1.0), VII (0.5-2.0), V (0.5-3.0), VI (0.5-4.0), II (0.5-4.0), IV (0.75-4.0) and I (1.0-4.0). VIII is an ideal accelerator but needs careful attention in its treatment. VII is the best of all accelerators studied. F. I. NAKAMURA

**The mode of action of organic accelerators of vulcanization.** L. PAUL BARY. *Rev. gén. caoutchouc* 6, No. 52, 3-8 (1929).—An historical review and discussion of different types of org. accelerators. Tables giving the trade name, chem. compn., phys. state, odor, activity and manufacturers of 24 aldehyde-amines, 14 salts of thio acids, guanidines and 10 miscellaneous classified compds. are included. C. C. D.

**Action of adipic esters (Sipaline) on accelerators of vulcanization.** Vulkan colors and rubber antioxidants. RUDOLF DITMAR WITH ALF. MATHIESEN AND KARL H. REUSSE. *Caoutchouc & gutta-percha* 26, 14618-20 (1929); cf. C. A. 23, 4098.—Tables

show the soly. of various accelerators, Vulkan colors and antioxidants in isopropyl methyladipate, in dimethylcyclohexyl methyladipate and in methylcyclohexyl adipate and the characteristic fluorescent colors of Vulkan colors in ultra-violet light. C. C. D

**The influence of various accelerators on the surface vulcanization of rubber by ultra-violet radiation.** RUDOLF DITMAR. *Gummi-Ztg.* 43, 2325(1929).—By continuing expts. (cf. C. A. 23, 2602) it is shown that when ordinary activators are omitted from accelerated rubber mixts., ultra-violet radiation has itself an activating effect. This activation is accompanied by oxidation of the rubber, and this oxidation is more effective than the vulcanization, so that from a practical point of view satisfactory vulcanization is possible only when a red or a yellow protective pigment, e. g., Se red, is added. With an activator like ZnO present in an accelerated mixt., ultra-violet radiation brings about vulcanization in a short time, so that the time must be carefully controlled to prevent oxidation, undercuring or overcuring. Ultra-violet radiation has the most favorable effect on rubber mixts. accelerated by tetramethylthiuram disulfide and contg. an activator. Surface vulcanization is complete in 45 min. without oxidation even in the absence of a protective red pigment. C. C. D

**The activating effect of various metallic oxides on the accelerating system piperidine pentamethylenedithiocarbamate and cyclohexylethylamine dithiocarbamate in the vulcanization of rubber in air.** RUDOLF DITMAR AND ALF MATHIESEN. *Chem.-Ztg.* 53, 479(1929).—The expts. are part of a study of the effect of metallic oxides on individual accelerators and on combinations of accelerators. From mixts. of pale crepe 100, colloidal S 3.5, piperidine pentamethylenedithiocarbamate 0.7, cyclohexylethylamine dithiocarbamate 0.7, "Agerite" 0.2 and metallic oxide or other compd. 10, in C<sub>6</sub>H<sub>6</sub>, films were prepd. by dipping and drying. These films were then cured in air with a rise of 30 min. to 100° and 60 min. at 100°. The following data give the oxide or other compd., its activating effect, the appearance of the vulcanizate, and the condition of the vulcanizate, resp.: CaO, strong, transparent, very good (the best of all); Ca stearate, none, transparent, tacky; SrO, strong, transparent, supple and very good; Sr stearate, none, transparent, tacky; SrCO<sub>3</sub>, none, milky, tacky; SrS, none, gray, tacky; SrO + Sb<sub>2</sub>O<sub>3</sub> + wax, none, milky, tacky; BaO, considerable, transparent, good but somewhat tacky; MgO, none, opaque, tacky; ZnO, strong, opal, very good and tight; ZnS, none, transparent, tacky; ZnSO<sub>4</sub> 5NH<sub>3</sub>, strong, almost transparent, very good; CdO, considerable, brown-red, very supple and good; CdS, none, yellow, tacky; HgS, none, red, tacky; BeO, none, transparent, tacky; Al<sub>2</sub>O<sub>3</sub>, none, transparent, tacky; Fe<sub>2</sub>O<sub>3</sub>, hardly any, red-brown, tacky; Ni<sub>2</sub>O<sub>3</sub>, none, approaching transparency, tacky; Co<sub>2</sub>O<sub>3</sub>, none, black, tacky; MoO<sub>3</sub>, none, opaque, tacky; SnO<sub>2</sub>, somewhat, milky—glass-like, tacky; SnS<sub>2</sub>, none, yellow-brown, tacky; Bi<sub>2</sub>O<sub>3</sub>, none, milky, tacky; Bi<sub>2</sub>S<sub>3</sub>, none, transparent, tacky; As<sub>2</sub>O<sub>3</sub>, considerable, transparent, good, Sb<sub>2</sub>O<sub>3</sub>, strong, orange-yellow, very good; Sb<sub>2</sub>S<sub>3</sub>, none, red, tacky; stearic acid, none, transparent, not vulcanized. It is considered that for this type of mixt., cured in air and required to be transparent, CaO and SrO are the best activators. C. C. DAVIS

**The consumption of accelerator during vulcanization.** L. v. WISTINGHAUSEN. *Rubber Age* (N. Y.) 25, 261-4, 319-21(1929).—An English version of C. A. 23, 3597. C. C. DAVIS

**Spray drying [in rubber preparation] (NYROP) 13. Method of preparation of artificial petroleum and of carboniferous decolorizing substances from raw rubber scrap or vulcanized scrap (NISHIDA) 22. Emulsions of rubber (Brit. pat. 301,805) 22. Rubber-bonded dry molding compositions (Brit. pat. 302,151) 18. Thermostat suitable for use with die blocks for molding rubber (U. S. pat. 1,720,837) 1. Plastic compositions [resembling hard or soft rubber] (Brit. pat. 302,270) 18.**

**Encyclopedie du caoutchouc et des industries qui s'y rattachent.** Edited by the SYNDICAT DU CAOUTCHOUC ET DES INDUSTRIES QUI S'Y RATTACHENT. Paris, 18 Rue Duphot: La revue générale du caoutchouc. 500 pp. Reviewed in *Rubber Chem. Tech.* 2, 1x(1929).

**KIRCHHOF, F.: Les progrès de la technologie du caoutchouc.** Paris: Ch. Berger. 259 pp. F. 55.

**Cellular rubber.** YVES CORNIC. Fr. 657,147, July 7, 1928. Substances capable of liberating CO<sub>2</sub>, NH<sub>3</sub>, or CH<sub>4</sub> are added to latex, which is then coagulated and vulcanized.

**Rubber articles.** ISTVÁN DOROGI, LAJOS DOROGI and DOROGI ES TARSÁ GUMMÓYAR R. T. Fr. 656,661, Jan. 27, 1928. Articles having thin walls are composed

one or more layers of rubber or the like and one or more layers of cellulose derivs. adhering to the rubber.

**Rubber articles.** SOC. ITALIANA PIRELLI. Fr 656,473, June 26, 1928. Rubber articles are made direct from latex by the addn. to the latex of oxides or hydroxides of bi- or ter-valent metals such as Zn, Mg, Ca, Al, assocd. with  $\text{NH}_4$  salts. Cf. C. A. 23, 3828.

**Deposition of rubber.** THE ANODE RUBBER CO. (ENGLAND), LTD. Fr. 657,364, Feb. 21, 1928. Deposition of rubber-contg. liquid dispersion prepd. with vulcanized rubber such as rubber regenerated from waste rubber or like substitutes of natural rubber is obtained on permanent supports. The deposition may be carried out according to any of the processes described in Fr. 574,552, 638,504, 619,649, 632,144, 619,682, 628,296, 647,413 (C. A. 23, 2603) or 647,232 (C. A. 23, 2603).

**Electrodeposition of rubber goods.** PAUL KLEIN and ANDREW SZEGVARI (to Anode Rubber Co., Ltd.). U. S. 1,719,984, July 9. In effecting electrodeposition of solids from an aq. rubber dispersion on to a depositing backing such as a gypsum-coated anode, liquids are removed from the dispersion concurrently with the deposition of solids from it and modification of the effectiveness of the electro-osmotic action is effected by varying the relative pressures to which the dispersion and removed liquids, resp., are subjected. An app. is described.

**Forming rubber tire tubes, etc., by deposition of superposed layers from thickened latex on a mandrel.** W. B. WESCOTT (to Rubber Latex Research Corp.). Brit. 302,182, Dec. 10, 1927. Each layer is dried before the next is applied. An app. is described.

**Crepe-rubber soles made from latex and containing an abrasive substance.** SOC. FINANCIÈRE DES CAOUTCHOUCS. Brit. 301,900, Dec. 9, 1927. Different methods are described of forming shoe soles or tread material from latex and finely divided materials such as silica, pumice or carborundum.

**Coating metals with rubber.** A. JENNY. Brit. 302,250, Dec. 12, 1927. Metals such as Al, Zn, Fe or their alloys are coated by use of an alk. dispersion of rubber such as latex and an alk. soln. of stick lac or shellac, in an electrophoretic deposition process. Vulcanizing agents may be added to the dispersion.

**Sheeting, strips and coatings of rubber.** DUNLOP RUBBER CO., LTD., D. F. TWISS and E. A. MURPHY. Brit. 302,201, Aug. 12, 1927. A concd. unvulcanized rubber latex compn. in the form of a cream is spread upon a moving surface and subjected to heat to effect setting or gelling as quickly as possible (the setting in the case of manuf. of coated fabrics occurring before the water in the dispersion penetrates the fabric to any substantial extent). Compns. as described in Brit. 290,313 (C. A. 23, 1012) or Brit. 219,635 (C. A. 19, 750) may be used, with or without various specified fillers and compounding and auxiliary ingredients.

**Bundle dipping process for coloring rubber bladders or toy balloons.** JOHN C. GIBSON (to Pioneer Rubber Co.). U. S. 1,720,594, July 9. Mech. features.

**Bonding rubber to metal surfaces.** HAROLD GRAY (to B. F. Goodrich Co.). U. S. 1,719,930, July 9. Previous to assocn. of a rubber compn. with a metal surface such as steel and vulcanization of the rubber under pressure, the metal is pretreated with substances such as  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , selenic acid, Se oxychloride,  $\text{SbCl}_5$ ,  $\text{SbBr}_3$ ,  $\text{Cu}_2\text{Cl}_2$ ,  $\text{FeF}_3$ , Pb chromate,  $\text{HgCl}_2$ , Ni chloride,  $\text{POCl}_3$ ,  $\text{PCl}_5$ ,  $\text{PCl}_3$ ,  $\text{AlCl}_3$ ,  $\text{FeCl}_3$ , chlorosulfonic acid,  $\text{TiCl}_4$ , Co chloride,  $\text{CuCl}_2$ ,  $\text{Me}_2\text{SO}_4$ ,  $\text{Et}_2\text{SO}_4$ ,  $\text{C}_2\text{Cl}_6$ ,  $\text{C}_2\text{HCl}_6$ , benzotrichloride, benzyl chloride,  $\text{CHI}_3$ , naphthalene tetrachloride, benzenesulfonylchloride, or *p*-nitrobenzoyl chloride, which serve to promote good adhesion between the metal and rubber. Cf. C. A. 23, 309.

**Coating iron or other metal surfaces with rubber.** F. AHNENS and HARZER ACHSENWERKE GES. Brit. 302,935, Dec. 21, 1927. The metal surface is first etched with a strong acid and there is then applied (repeatedly if necessary) a soln. of rubber  $\text{AmOAc}$  with or without  $\text{CCl}_4$ , to which swelling agents may be added, and a sheet of rubber is finally pressed on to the prepd. surface and, if not already vulcanized, may be vulcanized *in situ*.

**Rubber with variegated colorations.** GUMMI-UND BALATAWERKE MATADOR A.-G. and F. GREG. Brit. 302,102, April 2, 1928. Marbled, veined or streaked sheet material is formed by rolling or otherwise suitably working together portions of differently colored primary masses to which graded proportions of gas-forming and softening substances have been previously added. The primary materials may be partially vulcanized in order to secure sharper definition between the colors when they are combined.

**Adhesive rubber composition.** MERWYN C. TEAGUE (to General Rubber Co.). U. S. 1,719,948, July 9. See Can. 280,523 (C. A. 22, 2856).

**Preserving rubber.** A. M. CLIFFORD (to Goodyear Tire & Rubber Co.). Brit. 302,271, Dec. 13, 1927. Aging qualities of rubber are improved by addn. of compds. such as  $\beta$ , $\beta$ -dinaphthylamine or  $\alpha$ , $\beta$ -dinaphthylamine or other suitable secondary amines in which hydrocarbon radicals (preferably aryl) are of the same series. Details are given of the manuf. of the 2 compds. mentioned.

**Preserving rubber.** A. M. CLIFFORD (to Goodyear Tire and Rubber Co.). Brit. 302,144, Dec. 10, 1927. The "aging qualities" of rubber are improved by the addn. to the reaction product of an aromatic amine and an aliphatic acid or ester of such an acid, such as formnaphthalide,  $\beta$ -naphthylaminoaceto- $\beta$ -naphthalide, naphthylmonoformamide of ethylenediamine or the reaction product of  $\alpha$ - or  $\beta$ -naphthylamine and Et acetoacetate. Brit. 302,147 specifies the use of substances such as  $\alpha$ -chloro- $\beta$ -naphthol or  $\alpha$ -amino- $\beta$ -naphthol. Cf. C. A. 23, 3828.

**Preserving jelutong.** BEECHNUT PACKING CO. Brit. 302,850, March 29, 1928. Coagulated jelutong is preserved from oxidation by treating it with Na or  $\text{NH}_4$  primary or secondary phosphates or (less suitably) with  $\text{NH}_4$  tartrate, sulfate, chloride or acetate.

**Apparatus for stirring up dispersions particularly of rubber in water.** THE ANON. RUBBER CO. (ENGLAND), LTD. Fr. 656,660, Jan. 16, 1928.

**Vulcanization accelerators.** IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 657,177, July 9, 1928. Dithiocarbamates and thiuram sulfides of morpholine and its C-substituted derivs. which are used as vulcanization accelerators are prepd. by treating morpholine or its C-substituted derivs. with  $\text{CS}_2$ .

**Vulcanizing rubber.** CLAYTON W. BEDFORD (to B. F. Goodrich Co.). U. S. 1,719,920, July 9. A polysulfide of a thioamine such as *N*-dithioaniline is used as a vulcanizing agent or an accelerator. Cf. C. A. 23, 698.

**Vulcanizing rubber.** J. TEPPEMA (to Goodyear Tire and Rubber Co.) Brit. 302,142, Dec. 10, 1927. Vulcanization is accelerated by use of the reaction product of a 2-halobenzothiazole such as 2-chlorobenzothiazole and a dithiocarbamate such as Na diethyldithiocarbamate. The prepn. of the reaction product of 6-nitro 2-chlorobenzothiazole and Na diethyldithiocarbamate is also described and salts of piperidyl- and benzyldithiocarbamates, etc., also are referred to. Brit. 302,143 specifies the use as an accelerator of the reaction product of a benzoylnitrophenylsulfur halide such as 2-benzoyl-4-nitrophenylsulfur bromide and an alkali salt of an org. sulfide such as Na diethyldithiocarbamate. Cf. C. A. 23, 4103.

**Rubber vulcanization.** S. M. CADWELL (to Naugatuck Chemical Co.) Brit. 302,176, Nov. 1, 1926. An accelerator is used comprising a hydrolyzed halogen-free deriv. of aldehydeamine condensation products from an aldehyde having a plurality of C atoms in open chain such as the condensation product from heptaldehyde and aniline. Cf. C. A. 23, 1309.

**Rubber vulcanization.** WINFIELD SCOTT (to E. I. DUPONT DE NEMOURS & Co.) U. S. 1,721,057, July 16. A ditolyguanidine is used as an accelerator.

**Rubber vulcanization.** A. VOSHAGE. Brit. 301,802, Dec. 5, 1927. Vulcanizing molds are treated (suitably by spraying) with a soln. such as sugar and dextrin, to clean them and prevent formation of crust or scale.

**Synthetic rubber.** J. BAER. Brit. 302,399, Sept. 16, 1927. An elastic rubber-like product is obtained by the action of sulfides of  $\text{NH}_4$  or alkalis or alk. earths as polymerization agents on satd. halogenated hydrocarbons such as methylene or ethylene dichlorides, dibromides or diiodides. Cf. C. A. 23, 3376.

**Synthetic rubber.** I. G. FARBENIND. A.-G. Brit. 302,733, Dec. 21, 1927. A mixt. is formed of various polymerization products of the same hydrocarbon of the butadiene type, such as various polymerization products of isoprene. Cf. C. A. 23, 2324.

# CHEMICAL ABSTRACTS

Vol. 23.

SEPTEMBER 20, 1929

No. 18

## 1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

"New filter cylinders" for filtration apparatus. K. WAGENMANN. *Chem.-Ztg.* 53, 490(1929).—An upright glass tube attached to a horizontal flat disk, with a suitable opening, is inserted through a cork into a filter flask so that the disk forms a platform above. On these suction platforms are placed the "new" glass filter cups. These are interchangeable and of different sizes.

Simple extraction apparatus for liquids. H. BACH. *Chem.-Ztg.* 53, 517(1929).—An improved Baas and Bosmann app. (*Pharm. Weekblad* 9 (1893)) has a cock in the bottom of the extractor and a horizontal side-arm overflow connected into the vapor tube from the boiling flask to the top of the extractor and into the cooler. J. H. M. RUSSELL C. ERB

New bubble towers from old stills by use of special trays. PAUL TIESDELL. *Natl. Petroleum News* 21, No. 30, 65-8(1929). J. L. ESSEX

A pycnometer for viscous liquids. E. H. RIESENFELD AND T. HAMBURG. *Chem.-Ztg.* 53, 547(1929).—A shallow, thick-walled, glass vessel, of about 1.7-cc. capacity, is provided with a flat, ground-glass cover a little larger in diam. than the vessel. The pycnometer is filled so that the liquid to be examd. reaches a little above the edge. Then the cover is slipped on in such a way as to exclude air bubbles and the outside is wiped with filter paper. The cover will remain in position even if the pycnometer is inverted.

E. H.

A new differential pressure gage. A. R. OLSEN AND L. L. HIRST. *J. Am. Chem. Soc.* 51, 2378-9(1929).—The gage is simple and accurate and permits the study of very slow gas reactions at any pressure, even where an all-glass gage is needed. J. H. M.

Rapid-indicating continuous-reading vacuum and pressure gages. H. G. ANDERSON. *Ind. Eng. Chem.* 21, 795-7(1929).—The basic principles, the design, calibration and applications are given for 2 hot-wire gages which require no manipulation in the range from atm. pressure to 0.25 micron or less.

J. H. MOORE

[Apparatus for] experimental crystal structure analysis. A. GELLER. *Schweiz. mineral. petrog. Mitt.* 7, 219(1927). B. C. A.

Apparatus for incinerating plants for microscopical examination of the ash. O. WERNER. *Mikrochemie* 7, 110-5(1929).—The material to be ashed is placed between 2 perforated Al disks which fit into a thin cylindrical framework so as to leave a space between the disks. The framework is carried on an asbestos-covered iron gauze stretched on a rectangular framework over Teclu burners. The ash is mounted for microscopical examn. in fused phenol between two cover glasses joined around their circumferences with paraffin wax. For permanent mounting Canada balsam is used in place of phenol.

B. C. A.

Standard valves for chlorine containers. ROBERT T. BALDWIN. *Chem. Markets* 25, 169, 171, 173(1929); cf. *C. A.* 23, 3763-4. E. H.

Electrical measuring instruments for use in teaching electrochemistry. HENRY C. PARKER. *Met. Ind.* (London) 35, 55-8(1929); cf. *C. A.* 23, 2890. E. H.

An inexpensive Pyrex conductivity cell. W. BOYD CAMPBELL. *J. Am. Chem. Soc.* 51, 2419-20(1929).—An easily constructed cell, gas-tight at 5-atm. pressure, is described.

J. H. MOORE

A hydrogen microelectrode. R. WERNICKE AND F. MODERN. *Compt. rend. soc. biol.* 100, 133-5(1929).—An electrode vessel whose vol. is 0.4 cc. and whose design permits the measurement of 0.05-0.4 cc. is described. Loss of CO<sub>2</sub> is not prevented.

B. C. BRUNSTETTER

A quinhydrone microelectrode. L. BOËZ. *Compt. rend. soc. biol.* 101, 524-6(1929).—The microelectrode consists essentially of a Pt sheet in contact with quinhydrone between 2 cover-glasses, held fast by 2-3 drops of the liquid to be examd.

B. C. BRUNSTETTER

An improvement in thermostats with electric heating (remarks on P. Van Campen's

article of same title). L. HOCK AND C. L. NOTTEBOHM. *Z. Elektrochem.* **35**, 458 (1929).—Duane and Lory's app. (*Z. phys. Chem.* **36**, 613(1901); *Am. J. Science*, **9**, 179-82(1900)) has been improved so that a 50 l. thermostat may be held for hrs. at a temp. const. of  $1.10^{-1}$ . Cf. *C. A.* **23**, 3603.

A thermostat constant to one-thousandth of a degree centigrade. F. R. WINTON. *J. Sci. Instruments* **6**, 214-7(1929).  
J. H. MOORE  
E. H.

The thermoclement Te-Bi and its practical applications (LEVITSKII, LUKOMSKII) 2. The measurement of gas temperatures up to  $1500^{\circ}$  in radiation fields of changing anisotropy (SCHMIDT) 2.

**Thermometer.** WILLIAM G. ZIEGLER (to Consolidated Ashcroft Hancock Co., Inc.). U. S. 1,722,619, July 30. Structural features.

**Viscometer (of the rotating body resistance type).** I. G. FARBERIND. A.-G. Brit. 303,853, Jan. 11, 1928. Structural features.

**Filters.** SOC. ANON. DES PROCÉDÉS R. AUDUBERT. Fr. 657,693, Dec. 2, 1927. Forms of filters of the type having a network of fibers lying in the direction of filtration are described.

**Suction filter.** GEORGE H. DEAN. U. S. 1,722,626, July 30.

**Rotary filter for liquids.** H. A. VALLEZ. Brit. 303,707, April 23, 1928. Structural features.

**Laminated filter device.** V. R. HEFTLER. Brit. 303,153, Dec. 30, 1927. Structural features.

**Filter for air.** O. STOTT and MATTHEWS & YATES, LTD. Brit. 303,961, Nov. 10, 1927. Structural features.

**Air filter for use with internal-combustion engines.** C. BROWN and BROWN & BARLOW, LTD. Brit. 303,763, Oct. 4, 1927. Structural features.

**Oil-coated fabric air filter for internal combustion engines.** H. G. KAMRATH (to AC Spark Plug Co.). Brit. 303,807, Jan. 9, 1928. Structural features.

**Air purifier with moistened corrugated plates carried on an endless chain.** A. SCHIRP. Brit. 303,740, Jan. 7, 1928. Structural features.

**Filter press.** JOHN P. FOSTER. U. S. 1,722,497, July 30.

**Fractionating condenser.** DAVID T. WILLIAMS. U. S. 1,723,637, Aug. 6. Structural features.

**Rotary spraying device for treating liquids.** N. BENDIXEN. Brit. 302,980, Sept. 24, 1927. A device is described suitable for use in such operations as aging, blending, sterilizing, homogenizing, emulsifying or treating liquids generally with gases, rays or chemical emanations.

**Spray desiccation of milk, soap solutions, latex, etc.** N. J. NIELSEN. Brit. 303,576, Oct. 10, 1927. An app. is described in which a mixt. of hot air and superheated steam is used for treating the material. Two "drying cyclones" in series are used.

**Apparatus and system of spray desiccation for materials containing vitamins or other liquids.** WILLIAM S. BOWEN. U. S. 1,722,175, July 23.

**Float device for controlling heating apparatus (to prevent milk or other liquids from boiling over when heated).** T. W. A. RUSCHE. Brit. 303,372, Dec. 31, 1927. Structural features.

**Liquid distribution system suitable for hot water supply systems.** ERNEST J. AUTREY (one-half to Russell M. Simmons). U. S. 1,722,884, July 30. Structural features.

**Crystallizing apparatus.** FERNAND LAFEUILLE. Fr. 657,663, Nov. 30, 1927.

**Apparatus for centrifugal purification of liquids such as oils.** WILLIAM R. CHADBURN (to DeLaval Separator Co.). U. S. 1,723,329, Aug. 6. Structural features are described including connections for exhausting atm. air and substituting a neutral gas such as  $\text{CO}_2$  or N in the app. in order to prevent changes in the oil. Boiler-feed water may be similarly freed from O. Cf. *C. A.* **23**, 2078.

**Apparatus for vacuum distillation of oils, etc.** C. R. BURCH, F. E. BANCROFT and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 303,078, Sept. 21, 1927. The material is distd. in a highly evacuated chamber and condensed on a surface so located that the distance travelled by a particle of vapor is commensurate with the mean free path of a mol. of vapor of the residual gas such as Hg in the chamber. Various details of app. and procedure are described. Brit. 303,079 relates to similar app.

**Vacuum drying and distilling apparatus.** Firm of E. Mæxck. Brit. 303,661, Jan. 21, 1928. A wax, fat, fatty acid or the like in molten condition is used in a sealing channel of an app. which is described.

**Vacuum evaporating apparatus suitable for evaporating milk, etc.** GUSTAVE A. ZEITLER. U. S. 1,721,760, July 23. Structural features.

**Detecting leaks in high-vacuum apparatus.** W. DÄLLENBACH. Brit. 303,512, Jan. 5, 1928. High-vacuum app. of metal or glass is tested for leaks, prior to evacuation, by introducing a chemically active gas under pressure and covering the exterior surface with an indicator for the gas used. The use of  $\text{NH}_3$  with Nessler's reagent and other examples are described.

**Producing high vacua.** HUGH S. COOPER (to Kemet Laboratories Co., Inc.). U. S. 1,721,544, July 23. In devices such as x-ray or radio tubes, a metal of the alk. earth group is liberated by a non-gas-forming reaction, *e. g.*, by reaction of  $\text{BaO}$  with  $\text{Mg}$  induced by eddy currents, so that it absorbs gases present and forms solid compds. with them.

**Switch contacts operating in vacuum.** SIEMENS-SCHUCKERTWERKE A.-G. Brit. 303,899, Jan. 12, 1928. Contacts are made of material of high heat and elec. cond. which can be thoroughly freed from gases and the vacuum employed is higher than that usually employed in incandescent lamps.  $\text{Cu}$  or  $\text{Cu}$  alloys such as bronze are suitable and the dissipation of heat from the contacts is assisted by use of  $\text{Pb}$  in conductors with large surfaces.  $\text{Mg}$  may be used in forming the vacuum.

**Anodes for x-ray tubes.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 657,755, July 10, 1928. Method of molding anodes from finely powd. refractory metals by agglomeration.

**Electron-discharge bulbs.** SOC. ANON. DES ÉTABLISSEMENTS GAIFFE-GALLOT ET PILON. Fr. 658,189, Dec. 7, 1927.

**Electron-discharge tubes.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 34,278, Aug. 26, 1927. Addn. to 629,840.

**Electron-discharge device.** L. F. PERROTT and J. J. FITZPATRICK (to British Thomson-Houston Co., Ltd.). Brit. 303,381, Dec. 31, 1927. A cathode, formed from a refractory metal such as  $\text{Ni}$ , a  $\text{Ni}$  alloy,  $\text{Mo}$ ,  $\text{W}$ , or  $\text{Pt}$ , is coated with a compd. of an alk. earth metal such as  $\text{BaCO}_3$  or a mixt. of such compds., and heated to above  $1050^\circ$  until the surface becomes shiny and metallic in appearance. Various details of construction and procedure are described.

**Electron-discharge device.** SOC. DES ÉTABLISSEMENTS INDUSTRIELS DE E. C. ET DE A. GRAMMONT. Brit. 303,369, Dec. 31, 1927. The cathode is formed of a metal such as  $\text{Pt}$  or  $\text{Pd}$  (or may be formed of  $\text{W}$  coated with  $\text{Pt}$  or  $\text{Pd}$ ) and is provided with highly emissive material by first rendering it porous, coating it with an emissive substance such as  $\text{Ba}$ ,  $\text{Th}$ ,  $\text{Cs}$  or their salts, and is then restored to its original condition. Various details of treatment are described.

**Electron-discharge device.** JAMES R. WILSON (to Western Electric Co.). U. S. 1,722,121, July 23. A cathode is used with a thermionically active coating such as oxides of  $\text{Ba}$  and  $\text{Sr}$ , an anode, and a grid which is coated with  $\text{Al}$  and  $\text{Al}_2\text{O}_3$  or other suitable material capable of combining with particles from the cathode to form a thermionically inactive compd. and capable of fixing gases evolved within the device.

**Electron-emitting apparatus.** LE MATÉRIEL TÉLÉPHONIQUE (S. A.). Fr. 658,058, July 25, 1928.

**Electron-emitting cathodes.** LA RADIOTECHNIQUE. Fr. 34,112, July 6, 1927. Addn. to 637,962 (C. A. 23, 6).

**Thermionic tubes.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 658,088, July 26, 1928.

**Thermionic valve.** W. S. SMITH and N. W. MCLACHLAN. Brit. 303,037, Aug. 26, 1927. Structural features.

**Thermionic valves.** MARCONI'S WIRELESS TELEGRAPH CO., LTD. Fr. 658,049, July 25, 1928.

**Photoelectric cell.** LEE DE FOREST (to General Talking Pictures Corp.). U. S. 1,722,280, July 30. Structural features.

**Furnaces.** LOUIS H. FOURNIEUX. Fr. 657,698, Apr. 7, 1928. Method of operating doors.

**Furnaces burning powdered coal.** GEORGE P. HAYNES. Fr. 657,850, July 20, 1928.

**Rotating muffle furnace.** GEWERKSCHAFT SACHTLEBEN and JOHANN KÜPPERS. Fr. 34,200, Oct. 3, 1927. Addn. to 629,222.

**Regenerative furnace.** GEORGE H. ISLEY (to Morgan Construction Co.). U. S. 1,721,735, July 23. Structural features.

**Regenerative furnace suitable for open hearth or soaking pit installations.** GEORGE E. ROSE. U. S. 1,721,885, July 23.

**Apparatus for reversing and controlling regenerative furnaces.** GEORGE H. ISLEY (to Morgan Construction Co.). U. S. 1,722,701, July 30.

**Furnace for treating articles of circular or elliptical cross-section.** ANCIENS ETABLISSEMENTS LOY ET AUBÉ. Brit. 303,830, Jan. 10, 1928. Structural features.

**Furnace linings.** D. F. CAMPBELL and ELECTRIC FURNACE Co., LTD. Brit. 303,574, April 16, 1928. In forming furnace linings *in situ* (from refractory materials such as sand, ganister, silica, alumina or MgO, with or without clay, powdered glass, Na silicate etc.) the lining material is placed around a plug of graphite, W, or other high m. p. cond. material and the plug is heated by elec. currents from a surrounding coil. The plug may be wrapped with paper, the charred residue of which facilitates sepn. of the plug at the conclusion of the process.

**Gas burner.** J. and C. S. BOLINDERS MEKANISKA VERKSTADS AKTIEBOLAG and K. R. WESTER. Brit. 303,696, March 26, 1928.

**Gas burner.** HARRY E. KERR (to Cleveland Gas Burner & Appliance Co.). U. S. 1,723,180, Aug. 6.

**Gas burner.** HARRY C. TABLER (to American Heater Corp.). U. S. 1,722,066, July 23.

**Bunsen burner.** ERICH BANDOLY and HERMAN P. SACHSE (to Central Scientific Co.). U. S. 1,723,002, Aug. 6.

**Burner construction and control for oxyacetylene welding and similar operations.** J. L. ANDERSON (to Air Reduction Co.). Brit. 303,896, Jan. 13, 1928.

**Heat-exchange apparatus suitable for use as a condenser, still, etc.** ERNEST J. AUTREY (one-half to Russell M. Simmons). U. S. 1,722,883, July 30. Structural features.

**Apparatus for heating water or other liquid by heat from mercury vapor.** A. R. SMITH (to British Thomson-Houston Co., Ltd.). Brit. 303,013, Dec. 24, 1927. Structural features.

**Pressure vessels for gas.** PAUL BENKWITZ. Fr. 658,051, July 25, 1928. See Brit. 294,943 (*C. A.* 23, 1785).

**Apparatus for catalytic exothermic gas reactions.** I. G. FARBERIND. A.-G. Brit. 303,192, Sept. 23, 1927. The catalyst is contained in a plurality of tubes closely packed together to form a bundle and the interspaces between the tubes are so restricted relatively to the cross-section of the tubes and to the d. of the catalyst within the tubes that the incoming gas, which passes first on the outside of the tubes, travels at a higher velocity than it does within the tubes. Various structural details are described.

**Gas indicator operating on the diffusion principle.** HERMANN SEWERIN. U. S. 1,721,977, July 23. Structural features are described of a device suitable for use in mines.

**Gas-washing apparatus.** JOHN C. HAYES, JR. (to Freyn Engineering Co.). U. S. 1,722,466, July 30. Structural features.

**Gas holder.** MASCHINENFABRIK AUGSBURG-NÜRNBERG A.-G. Brit. 303,471, Jan. 4, 1928. A thin continuous metal sealing closure ring which may be formed of Fe, Cu or Al strips welded or riveted together and which is of such thickness and resiliency as to conform with irregularities in the shape of the gas holder is pressed by levers against the holder wall and may be faced with felt or similar material. Various structural details are described.

**Ozonizer.** CHARLES J. V. FÉRY. Fr. 657,932, Dec. 7, 1927.

**Sealed joints between metal and glass.** SIEMENS-REINIGER-VEIPA GES. FÜR MEDIZINISCHE TECHNIK. Brit. 303,348, Dec. 31, 1927. An alloy of Ni and Cr (preferably contg. Ni 60-90%) is used at the place of sealing, in the *manuf. of vacuum tubes* or other articles.

**Apparatus for centrifugal casting or lining of pipes with metal or cement.** R. A. WHITSON. Brit. 303,829, Jan. 10, 1928. Structural features.

**Apparatus for handling crucibles such as those used in making metal castings.** HOLLEY G. WELLMAN. U. S. 1,722,777, July 30. Structural features.

**Upward-current apparatus for washing and classifying ores, coal, etc.** L. HOVOIS. Brit. 303,810, Jan. 9, 1928. Structural features.

**Apparatus for mixing, compacting, degassing or grinding viscid materials in thin layers.** ASBJORN SONSTHAGEN and GUDOLF M. PÖVERUD. U. S. 1,722,115, July 23. Structural features.

**Apparatus for mixing subdivided solids with liquids by jets of compressed air or gas.** P. HIRSCHFELDER (D. Stewart & Co., Ltd.). Brit. 303,839, July 11, 1928. Structural features.

**Apparatus for impregnating and drying sheet materials.** HORACE M. EATON (to Norman Edmunds). U. S. 1,723,336, Aug. 6.

**Apparatus for applying paraffin, resin, asphalt, or other waterproofing material to wet fibrous webs.** HAROLD L. LEVIN (to Flintkote Co.). U. S. 1,723,361, Aug. 6. Structural features.

**Penetrator apparatus for testing the hardness of various materials.** ROBERT K. BARRY and LEONARD BOWEN. U. S. 1,722,263, July 30. Structural features.

**Apparatus for testing the dielectric strength of insulating materials.** ARTHUR O. AUSTIN (to Ohio Brass Co.). U. S. 1,721,847, July 23.

**Control device for warning signals of buoys or other apparatus actuated by variations in light.** J. NEALE. Brit. 303,224, Oct. 12, 1927. Structural features of app. controlled by a light-sensitive cell.

**Acetylene generator of the carbide-feed type.** CLARENCE J. COBERLY, ROBERT G. WULFF and WALTER H. HOLLAND (to Union Carbide and Carbon Research Laboratories, Inc.). U. S. 1,723,679, Aug. 6. Structural features.

**Luminous electric discharge tubes.** REGNIER FRANCOITTE. U. S. 1,723,929, Aug. 6. Gases occluded in the electrodes are eliminated, during manuf., by exposure to elec. discharges in a sep. tube filled with N, at a regulated current intensity; the purified electrodes are mounted in end branches of the tubes, the branches are fused to the tubes and the luminous tube thus formed is purified by means of elec. discharges in a N filling with subsequent absorption of residual gases by an auxiliary electrode of Pd; the tube is emptied and filled with a purified rare gas such as He or Ne.

**Thermocouple apparatus for measuring superheat in boilers.** THOMAS R. HARRISON (to Brown Instrument Co.). U. S. 1,721,556, July 23. Structural and elec. features.

**Thermostatic control for water heaters.** EMIL HOWE. U. S. 1,723,239, Aug. 6. Structural features.

**Thermostatic control for electric circuits.** ALBERT E. WHITTIER. U. S. reissue 17,391, July 30. See original pat. 1,713,578 (C. A. 23, 3381).

**Thermostat for control of electric circuits.** EUGENE T. VINCENT. U. S. 1,722,186, July 23. Structural features.

**Thermostat with alternating current.** I. E. DMITRIEV. Russ. 5773, June 30, 1928.

## 2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

**The life of Sir Humphrey Davy.** J. MCCRAE. *J. Chem. Met. Mining Soc. S. Africa* 29, 244–53 (1929). E. H.

**Charles Moureu.** CAMILLE MATIGNON. *Chimie et industrie* 21, 1129–30; *Chemistry & Industry* 48, 735–6 (1929).—An obituary. A. PAPINEAU-COUTURE

**Eugène Risler (1828–1905).** His life and work. ALBERT BRUNO. *Bull. soc. ind. Mulhouse* 95, 209–16 (1929).—Biographical, with a bibliography of his principal publications. A. PAPINEAU-COUTURE

**Vladimir Efimovich Grum-Grzhimailo (1864–1928).** LÉON DLOUGATCH. *Rev. métal.* 26, 391–2 (1929).—Biographical, with portrait. A. PAPINEAU-COUTURE

**Memorial service for Edgar Fahs Smith.** The Provost of the University of Pennsylvania presiding. WILLIAM B. IRVINE. Auditorium University of Pennsylvania, December 4, 1928. Brochure, 62 pp.—Contains a portrait of Smith, a biographical summary, a bibliography of his publications and of Ph.D. theses prepd. under his direction, the invocation and benediction by Richard Montgomery, and memorial addresses by Francis Xavier Dercum, Marston Taylor Bogert and Josiah Harmar Penniman. JOSEPH S. HEPBURN

**The Kaiser Wilhelm Gesellschaft zur Foerderung der Wissenschaften.** EDOUARD VINCENT. *Chimie et industrie* 21, 1298–1304 (1929).—A brief outline of the origin and of the chem. activities of this society. A. PAPINEAU-COUTURE

**The Physical Institute of the Technische Hochschule at Munich.** J. ZEMNECK. *Physik. Z.* 30, 433–58 (1929).—The design and equipment of the institute are described. E. H.

**Bibliography of bibliographies on chemistry and chemical technology.** CLARENCE J. WEST and D. D. BEROLZHEIMER. *Natl. Research Council Bull.* 71, 161 pp. (1929). E. H.

**Discovery of the gas laws. II. Gay-Lussac's law.** W. S. JAMES. *Science Progress* 24, 57–71 (1929); cf. C. A. 22, 4284.—An account of the studies concerning the

influence of the temp. on the vol. of (a) air and (b) gaseous elements and compds., from the researches of Amontons (1699-1702) to those of Gay-Lussac (1802-1816), with a summary of the subsequent history of the law.

JOSEPH S. HEPBURN

**A rational method for balancing exceptional chemical equations.** BART PARK. *J. Chem. Education* 6, 1136-8(1929).—An extension of the method of balancing equations involving oxidation and reduction, using changes in valence of oxidizing agent and reducing agent to indicate how many mols. of each need be taken, demands additional algebraic assumptions if the processes are very complicated. Such processes are illustrated by equations like (a)  $2K_4Fe(CN)_6 + 24H_2SO_4 = 4K_2SO_4 + Fe_2(SO_4)_3 + 6(NH_4)_2SO_4 + 11SO_2 + 10CO_2 + 2CO$  and (b)  $2K_4Fe(CN)_6 + 12K_2S_2O_8 = 12KCNS + 9K_2SO_4 + K_2S + 2FeS$ , which are balanced step by step.

W. C. EBAUGH

**Nomography.** OTTO LIESCHKE. *Chem. Fabrik* 1929, 305-6.—A chart for heat loss due to incomplete combustion of flue gas. Cf. *C. A.* 23, 2552.

J. H. MOORE

**Vacuum contraction of density bulbs.** MARCEL BECKERS. *J. Am. Chem. Soc.* 51, 2042-51(1929).—A detailed description of the technic used in detg. contraction of evacuated flasks is given. It can be calcd. by means of the empirical equation  $\eta = KV/W$ , where  $\eta$  is the compressibility per l. and atm.,  $V$  the vol. in l.,  $W$  the wt. of the glass minus the stopcock in g. and  $K = 16$ . The accuracy is within a few percent. The contraction is a linear function of the pressure.

FRANK URBAN

**Note on the platinum thermometer temperature scale.** F. E. HOARE. *Phil. Mag.* [7], 7, 384-6(1929).—A useful expression is obtained for calcg. the difference coeff. for Pt thermometers. By using this expression temps. are obtained which are correct to  $0.1^\circ$ .

L. H. REYERSON

**Empirical formulas for platinum—90% platinum + 10% rhodium thermel.** MOTOTARO MATSUI. *J. Soc. Chem. Ind. (Japan)* 32, 33-8(1929); Suppl. binding 32, 12-4B.—Seven types of interpolation formulas for the thermels and convenient methods of computation are discussed. For the temp. range  $300^\circ$  to  $1200^\circ$  the best formulas are:  $e = -a + bt + ct^2$  and  $e = a + bt + ct^2 + dt^3$ . The formula  $t = a + be - ce^2$  is convenient for calcg. the temp. from the e. m. f. measured ( $e =$  e. m. f. in  $\mu V$  and  $t =$  temp. in degrees C. and  $a, b, c$  and  $d$  are consts.) For Pt—90% Pt + 10% Rh thermel of the first quality, the consts.  $a, b$  and  $c$  of the first and the last of the above formulas are always the same.

S. KONDO

**The measurement of the electromotive force of the thermel at the freezing point of standard pyrometric samples.** MOTOTARO MATSUI AND SEIZO OKA. *J. Soc. Chem. Ind. (Japan)* 32, 38-43(1929); Suppl. binding 32, 14-6B.—The e. m. fs. of Pt—90% Pt + 10% Rh thermels, supplied by Siemens-Halske and Leeds-Northrup, were measured at the f. ps. of standard pyrometric samples certified by the U. S. Bureau of Standards. The f. ps. of the pure metals of different origins were computed by the empirical formulas and compared with those fixed by the Physikalische-technische Reichsanstalt in 1924.

S. KONDO

**The thermoelement tellurium-bismuth and its practical applications.** M. A. LEVITSKII AND M. A. LUKOMSKII. *Physik. Z.* 30, 203-5(1929).—Since Te and Bi stand at the 2 extremes of the thermoelec. series, the pair should be the most sensitive for use as a thermocouple. Te has a transition point at  $354^\circ$  and its resistance and other elec. properties are variable after it has been heated. For small differences in temp., however, the metal can be used with Bi for temp. measurements after calibration. On account of its high resistance the contact should be made large and constantan wire used as the leads. Such a couple gives a current of 360 microvolts per degree, or about 3 times that of the Fe-constantan couple. It has been used for measuring the energy of radiation, including that of the H lines.

H. F. JOHNSTONE

**Chemical reactions of dried substances. I. Ammonia and phosphorus pentoxide.** LOUIS HARRIS AND CHARLES B. WOOSTER. *J. Am. Chem. Soc.* 51, 2121-6(1929).—Pure  $P_2O_5$  absorbs rapidly appreciable quantities of carefully dried  $NH_3$ . The reaction product apparently forms a protective film upon the  $P_2O_5$  and retards further absorption.

N. M. BOUDER

**Revision of the weight of a normal liter of carbon monoxide gas.** L. R. PIRE AND E. MOLES. *Anales soc. espñ. fis. quim.* 27, 267-72(1929).—Very pure CO, obtained by dehydration of  $HCOOH$  with  $H_2SO_4$ , purified and dried over KOH and concd.  $H_2SO_4$  and  $P_2O_5$ , was used. The mean value of 7 detns. agreeing well, with corrections, was  $1.25011 \pm 0.00005$ . With the most probable value for deviation from Avogadro's law  $1 + \lambda = 1.00050$  the at. wt. of C = 12.006, somewhat higher than the international value but agreeing with the latest Aston results.

E. M. SYMMES

**Atomic weight of phosphorus.** MOWBRAY RITCHIE. *Nature* 123, 838 (1929).—The normal d.  $L_0^{760}$  of phosphine is at 1 atm., 1.5317; at  $1/2$  atm., 1.5243. If the compressi-

bility factor is linear, the value of  $(1 + \lambda)$  is 1.0097, which, in conjunction with the normal d. of  $O_2$  of 1.4290 and  $(1 + \lambda) = 1.0009$ , leads to the mol. wt. of 34.00 (2) for  $PH_3$  and 30.97 (9) for the at. wt. of P. Some results obtained at  $1/4$  atm. give  $L_0^{760} = 1.5208$ , for which  $(1 + \lambda) = 1.0096$  and  $P = 30.98$  (2). The Sub-committee of the Chemical Society adopts the value  $P = 30.98$  (2) based on mass spectrographic analysis. (*J. Chem. Soc.* 1929, 216-7) while the German commission adheres to the older value 31.02, based mainly on gravimetric analysis.

**The atomic weight of copper.** W. M. HICKS. *Nature* 123, 83<sup>o</sup> (1929).—In connection with Richards and Phillips' detn. of the at. wt. of Cu as 63.557 (cf. *C. A.* 23, 1536) it is pointed out that the spectroscopic value of the at. wt. of Cu, depending on the doublet sepn. of the  $p(1)$  term, is  $63.5569 \pm 0.060$ .

**Para- and ortho-hydrogen.** K. F. BONHOEFFER AND P. HARTECK. *Z. physik. Chem.*, Abt. B, 4, 113-41 (1929); cf. *C. A.* 23, 2614.—A calcn. of the probability of transition of the symmetrical into the antisymmetrical hydrogen by spontaneous radiation is presented by Wigner. Spectral properties of parahydrogen are discussed. Ortho- and para-systems are forecast for  $C_2$ ,  $N_2$ ,  $F_2$ ,  $Cl_2$  and  $I_2$ . The ratio ortho/para for  $N_2$  is probably 2:1, for  $F_2$  it is 3:1.

**Report on the vapor pressure of solid and liquid neon and liquid helium.** J. E. VERSCHAFFELT. *Comm. Phys. Lab. Univ. Leiden*, Suppl. 64, 31-6 (1929).—Measured values for the vapor pressure of solid Ne (in atms.) from  $15.47^\circ$  to  $24.53^\circ K$ . may be expressed according to the equation  $\log_{10} p = -(112.8/T) + 4.22$ . For liquid Ne from  $24.58^\circ$  to  $44.43^\circ K$ . is given the equation  $T \log_{10} p = 28.100 + 3.600(T - 35) + 0.003333(T - 35)^2 + 0.000400(T - 35)^3 + 0.00002667(T - 35)^4$ . Combining the equations gives for the triple point  $T = 24.40^\circ K$ . and  $p = 0.394$  atm. The heat of vaporization of solid Ne is calcd. to be 25.7 cal. per g. Just how the vapor-pressure curve for He extends around abs. zero is not definitely known.

**Solid elements.** W. HERZ. *Z. anorg. allgem. Chem.* 180, 284-6 (1929); cf. *C. A.* 23, 2338.—Since  $S\sqrt{s} = K$  and  $S\sqrt{L} = K'$ , it follows that  $\sqrt{L}s = K''$ .  $S =$  entropy;  $s =$  sp. heat of the solid element;  $L =$  heat of vaporization. Use as alternatives to the law of Dulong and Petit is suggested.

**Boiling temperatures of magnesium, calcium, strontium, barium and lithium.** H. HARTMANN AND R. SCHNEIDER. *Z. anorg. allgem. Chem.* 180, 275-83 (1929).—The vapor pressure of each liquid metal was measured and the b. p. detd. by plotting  $\log p$  vs.  $1/T$  and extrapolating to atm. pressure. The following values were found: Mg  $1380^\circ \pm 5$ , Ca  $1712^\circ \pm 5$ , Sr  $1639^\circ \pm 5$ , Ba  $1810^\circ \pm 10$ , Li  $1609^\circ \pm 5$ . Values for the mean mol. heat of vaporization, the Trouton const., the chem. const. and the crit. point were calcd., for each metal.

**Comment on a paper by A. M. Berkenheim, entitled: New regularities in the series of ionic radii of elements.** V. M. GOLDSCHMIDT. *Z. physik. Chem.* Abt. A, 141, 451-2 (1929); cf. *C. A.* 23, 2860.—Polemic against the use of the present author's exptl. data on ionic radii in conjunction with Berkenheim's calcd. radii to discredit the values calcd. by Pauling and others. At present some of the calcd. values are preferred to the exptl. ones, and vice versa.

**Contribution to the anodic behavior of aluminum.** W. J. MÜLLER AND K. KONOPICKY. *Z. physik. Chem.*, Abt. A, 141, 343-77 (1929); cf. *C. A.* 22, 3090.—On the basis of exptl. data obtained from measurements on an Al anode in a rectifier, a cataphoretic theory of the rectifying action is developed. A quant. formula of the same form as that derived previously is found to be in good agreement with the exptl. results, and the cataphoretic theory confirmed.

**Magnetic properties of isolated atoms of cobalt.** F. W. CONSTANT. *Nature* 123, 943-4 (1929).—In alloys of 10 or 5% Co with 90 or 95% Pt, resp., it is assumed that the Co atoms are isolated by being surrounded by the non-ferromagnetic Pt atoms. These alloys are ferromagnetic with Curie points at  $249^\circ$  and  $49^\circ$ , resp. Between liquid-air temp. and the Curie point, the intensity of magnetization,  $I$ , at first increases with rise of temp. for low fields (i. e.,  $H$  less than 100 gauss), but for higher fields it decreases steadily with increase in temp. The greatest values for  $I$ , viz., 364 c. g. s. units for the 10% and 254 c. g. s. units for the 5% alloy, were obtained for  $H = 565$  gauss. These values correspond to magnetic moments for the Co atom greater by 25% and by 60%, resp., than that calcd. from the satn. value for pure Co. The hysteresis loops vary with the previous heat treatment. When hard-drawn, the 5% alloy gave the larger and more rectangular loops. After annealing, the hysteresis was greatly reduced and the coercive force for the 5% alloy was 20 gauss against 28 gauss for the 10%. This last result is in accord with Heisenberg's theory of ferromagnetism. W. W. STIFLER

Valence forces as calculated from specific heats and spectra. DONALD H. ANDREWS. *Chem. Reviews* 5, 533-48(1928).—A review of some applications of classical mechanics to the study of the chemical bond. W. W.

Magnetostriction and the phenomena of the Curie point. R. H. FOWLER AND P. KAPITZA. *Proc. Roy. Soc. (London)* 124A, 1-15(1929).—A summary is given of Heisenberg's theory of ferromagnetism, but in the calcn. of the partition function for a magnetized crystal certain terms are retained which were irrelevant in the primary investigation since they do not depend upon the applied magnetic field. The results of this calcn. are then applied to the general explanation of the nature of the Curie point, the changes in sp. heat and in size at the Curie temp. and magnetostriction. These fit satisfactorily into Heisenberg's theory, although at present only a rough quant. comparison is attempted. W. W. STIFLER

The two Curie points, ferromagnetic and paramagnetic. ROBERT FORRER. *Compt. rend.* 188, 1242-4(1929).—The temp. at which ferromagnetism disappears is called the ferromagnetic Curie point,  $\theta_F$ . The paramagnetic Curie point,  $\theta_P$ , is the temp. given by the Weiss law  $\chi(T - \theta) = C$ . As a rule  $\theta_P$  is from 15° to 40° higher than  $\theta_F$ . For Ni, the form of the cycle and the ratio of the remanent magnetization to the satn. value suggest the hypothesis that half of the elementary magnetic moments are parallel, and half perpendicular to the field. The crit. field is then the field necessary to reverse those parallel to the field. In the neighborhood of  $\theta_F$ , this crit. field is an almost linear function of the temp. and it has a definite finite value at  $\theta_P$ . When extrapolated, the curve cuts the temp. axis very nearly at  $\theta_P$ , 14° above  $\theta_F$ . The existence of the two Curie points reveals the simultaneous existence of two different properties: The region above  $\theta_P$  is characterized by the existence of a spontaneous orientation. But the region of hysteresis extends just to  $\theta_F$ . In this region the reversal of the magnetic moments requires a certain definite field. The reversal becomes spontaneous for  $\theta_P$  and the region above it. For Ni, Fe and Co,  $\theta_P$  is above  $\theta_F$  and this is considered the normal case. It is also true for most ferromagnetic alloys but for the ferrocobalt studied by Preuss,  $\theta_P$  lies below  $\theta_F$ . To obtain a spontaneous magnetization, the existence of a magnetic moment and a spontaneous orientation is not sufficient. Hysteresis also is necessary. Ferromagnetism does not exist except below the two Curie points. On the contrary, paramagnetism is limited uniquely by  $\theta_P$ . W. W. STIFLER

Magnetic properties of the sesquioxide of iron and of certain ferrites above their Curie point; conservation of the constant paramagnetism in these compounds. MILLE A. SERRRES. *Compt. rend.* 188, 1239-41(1929).—Measurements on 2 samples of  $Fe_2O_3$  at several temps. between 700° and 750° gave a mean value for the susceptibility of  $19.70 \times 10^{-6}$ , accurate to about 0.3%. This gives a susceptibility per g. of Fe of  $28.17 \times 10^{-6}$ . This value lies between the extremes of those given by various authors for  $\gamma Fe$ ; whence S. concludes that the paramagnetism of  $\gamma Fe$  is conserved in combination. Measurements on 4 ferrites ( $Fe_2O_3 \cdot NiO$ ,  $Fe_2O_3 \cdot PbO$ ,  $Fe_2O_3 \cdot CuO$ ,  $Fe_2O_3 \cdot MgO$ ) in the same temp. range did not give a linear relation between temp. and reciprocal of susceptibility. This is contrary to the results of Kopp on magnetite. But on correcting for the paramagnetism of the Fe, the relation becomes linear. Thus the hypothesis of a const. paramagnetism superimposed upon a variable paramagnetism is confirmed. W. W. STIFLER

Ferromagnetic properties of the ferrites. SUZANNE VEIL. *Compt. rend.* 188, 1293-4(1929).—Previous work has shown that the ppt. obtained by treating with soda a cold soln. of a ferric salt mixed with a nickelous or cobaltous salt of the same anion gives, when calcined, a ferromagnetic anhydride. This effect is particularly pronounced when the two salts are mixed in mol. proportions. The work is now extended to solns. in which Cu is substituted for the Ni or Co, with similar results. Although before calcination the hydroxides are paramagnetic, heating for some hrs. at 120° in sealed tubes renders them ferromagnetic. On substituting Ni or Co for Fe, the mixed ppts. do not exhibit ferromagnetism when heated to 120°. Also the increase in coeff. of magnetization on heating is comparatively slight and decidedly less than that shown by the Cu ferrite. It is therefore concluded that Fe is sharply distinguished, ferromagnetically, from Ni and Co. W. W. STIFLER

Diamagnetism and crystal structure. C. V. RAMAN. *Nature* 123, 945 (1929).—Ehrenfest has suggested that the high diamagnetic susceptibility of Bi may be due to

the existence in the crystal lattice of electron orbits of such large area as to include several atoms within their radius. R. applies this idea to explain the differences between the diamagnetic susceptibilities of graphite ( $-5.1 \times 10^{-6}$ ) and diamond ( $0-.49 \times 10^{-6}$ ). This hypothesis of electron orbits circulating around the plane hexagonal rings of C in the crystal lattice may also explain the observations of Honda and Owen that the susceptibility of graphite is several times as great in a direction normal to the planes of cleavage as it is parallel to them.

W. W. STIFLER

**Crystal structure and ferromagnetism.** W. SCHMIDT. *Physik. Z.* 30, 259-61 (1929).—When the temps. at which various transformations occur in Fe are expressed on the abs. scale, it is found that they can be expressed to a fair approximation by  $T = nT_c/m$ , in which  $T_c$  is the m. p. (for Fe =  $1803^\circ$  abs.);  $m = 14$ , and  $n$  is an integer between 1 and 13 inclusive. The values of  $T$  corresponding to values of  $n$  from 1 to 13 are tabulated and the corresponding phenomena are noted. No transformations are known corresponding to  $n = 1, 5$  and 6. In general, the agreement is only approx.; e. g., for  $n = 12$ ,  $T = 1545.6$ , while the Curie temp. =  $1553^\circ$ . The same equation can be applied to Sn.

W. W. STIFLER

**The fundamental law of paramagnetic magnetization of a crystal and the law of paramagnetic rotary dispersion.** JEAN BECQUEREL AND W. J. DE HAAS. *Compt. rend.* 188, 1156-8 (1929).—The paramagnetic rotary power of tysonite as a function of  $H/T$  is represented by a hyperbolic tangent law. ( $H$  = magnetic field;  $T$  = abs. temp.) Within the limits of error with which low temps. can be measured, this gives a magnetic moment of one Bohr magneton. B. and de H. apply Ladenburg's formula, neglecting the diamagnetic effect which is negligibly small in tysonite compared to the paramagnetic. The calcd. results are in excellent agreement with the exptl. The hyperbolic tangent law is concluded to be an indication of a reversal of sense of the magnetic moment. Certain theoretical conclusions follow.

W. W. STIFLER

**Magnetic behavior of organic crystals.** C. V. RAMAN. *Nature* 123, 605 (1929).—In general, the optical and magnetic characters of aromatic compds. are related. For naphthalene the axes of max. diamagnetic susceptibility and of min. optical dielec. const. are approx. coincident. For aliphatic crystals, however, the magnetic and optical characters are more varied. In  $\text{CH}_4$  the axes of max. magnetic susceptibility and optical dielec. const. are parallel, while in urea they are crossed.

H. F. JOHNSTONE

**Diamagnetism of certain binary halogen compounds.** R. HOCART. *Compt. rend.* 188, 1151-3 (1929).—Measurements by 2 different methods were made on solns. of NaCl, KCl and HCl, and on solid NaCl and KCl. Special precautions were taken to insure purity; the exptl. error is less than 0.5%. The mol. susceptibilities are: for HCl,  $-22.0 \times 10^{-6}$ ; for NaCl in aq. soln.,  $-30.8 \times 10^{-6}$ ; for solid NaCl,  $-30.1 \times 10^{-6}$ ; for KCl in aq. soln.,  $-39.60 \times 10^{-6}$ ; and for solid KCl,  $-39.1 \times 10^{-6}$ . The discrepancies between solid and soln. for NaCl and KCl are interpreted as indicating that the diamagnetism of the ions is not strictly additive. Susceptibilities for other compds., accurate to about 1%, are: KBr,  $-49.1 \times 10^{-6}$ ; KI,  $-63.8 \times 10^{-6}$ ;  $\text{MgCl}_2$ ,  $-47.4 \times 10^{-6}$ ;  $\text{CaCl}_2$ ,  $-54.4 \times 10^{-6}$ ;  $\text{SrCl}_2$ ,  $-63.0 \times 10^{-6}$ ;  $\text{BaCl}_2$ ,  $-72.6 \times 10^{-6}$ .

W. W. STIFLER

**Diamagnetism of the crystal of azoxyanisole and the Larmor precession.** G. FOËX. *Compt. rend.* 188, 1154-6 (1929).—Measurements on two crystals (monoclinic) of *p*-azoxyanisole gave, as the susceptibility along the axis of symmetry,  $\chi_1 = -6.65 \times 10^{-7}$  while in the plane of symmetry the values were  $\chi_2 = -6.34 \times 10^{-7}$  and  $\chi_3 = -4.08 \times 10^{-7}$ . Between room temp. and  $-79^\circ$ ,  $\chi_3$  is const. within 1%. From these data F. concludes that Larmor's theorem is not applicable to this crystal. He also calls attention to certain other possible theoretical deductions.

W. W. STIFLER

**The properties of dielectrics. II. The dielectric constant.** F. M. CLARK. *J. Franklin Inst.* 208, 17-44 (1929).—A review of the effect of temp., pressure, frequency and voltage on the dielec. strength of gases, liquids and solids.

ARTHUR FLEISCHER

**X-ray evidence for intermolecular forces in liquids.** J. A. PRINS. *Nature* 123, 908-9 (1929).—The diffraction pattern of liquids inside the principal halo is related only to the mutual arrangement of the mols. Small diffraction angles are a measure of the tendency to assocn. in a dynamic rather than a static sense. The x-ray affords an exceptionally sensitive method of studying intermol. forces.

I. J. PATTON

**Dehydration of benzene.** J. J. MANLEY. *Nature* 123, 907 (1929).—Measurements of the refractivity of  $\text{C}_6\text{H}_6$  in contact with  $\text{P}_2\text{O}_5$  show a curve with two distinct smooth portions, having different slopes, the first probably representing the rate of removal of mechanically admixed water, and the second the rate of withdrawal of combined water. The conclusion that  $\text{C}_6\text{H}_6$  forms one or more hydrates is strengthened by some expts. on the sp. vol. of  $\text{C}_6\text{H}_6$  in the presence of  $\text{P}_2\text{O}_5$ .

I. J. PATTON

**Optical properties of some salts of gluconic acid.** GEORGE L. KEENAN AND SAMUEL M. WEISBERG. *J. Phys. Chem.* 33, 791-4 (1929).—The  $\text{NH}_4$ , Na, K, Ba and Pb salts of gluconic acid as well as the gluconic  $\gamma$ -lactone were prepd. and their optical properties (refractive indices and effect of polarized light) studied so as to obtain data for their identification.

**The differences of potential between metals and air.** MARIE ANDAUER. *Z. physik. Chem., Abt. A*, 138, 357-68 (1928); cf. *C. A.* 21, 1400.—Metal plate was inserted under the opening in the bottom plate of an  $\alpha$ -electroscope. The air between the bottom plate and the inserted metal plate was ionized by means of Po, and the influence of the potential between the metal plate and the grounded electroscope upon the velocity of discharge was detd. Potentials thus found were: Al  $-0.83$  v., Zn  $-0.74$  v., Ni  $-0.32$  v., Fe  $-0.15$  v., Sb  $-0.16$  v., Sn plate  $-0.12$  v., brass  $-0.10$  v., Bi  $-0.07$  v., Cu  $+0.13$  v., Ag  $+0.16$  v., Pt  $+0.25$  v.

**The nomenclature of the thirty-two crystal classes.** FRIEDRICH RINNE. *Abhandl. math.-phys. Klasse sächs. Akad. Wiss.* 40, No. 5, 1-8 (1929). E. H.

**A new derivation and nomenclature of the 230 crystallographic space groups.** ERNST SCHIEBOLD. *Abhandl. math.-phys. Klasse sächs. Akad. Wiss.* 40, No. 5, 9-204 (1929).—The text is accompanied by an atlas, under sep. cover, of the 230 space-group projections. E. H.

**Crystal structure and chemical constitution.** V. M. GOLDSCHMIDT. *Trans. Faraday Soc.* 25, 253-83 (1929); cf. *C. A.* 23, 2618.—The fundamental law of cryst. chem. is defined by the statement that the structure of a crystal is detd. by the relative nos., by the relative sizes and by the polarization properties of atoms, atom groups and ions. The inductive method for detg. the laws of cryst. chem. is explained. The phenomena of *isomorphism*, *morphotropism* and *polymorphism* are taken up from the viewpoint of the above mentioned law. A classification of crystals according to coordination types rather than by macro-cryst. symmetry is used. Tables of coordination types, of ionic radii, of the radius quotient  $R_A:R_X$ , changes in atomic distances, etc., are included. Ionic and non-ionic crystals are used as examples in the discussion. Substances of the  $\text{AX}$ ,  $\text{AX}_2$ ,  $\text{A}_2\text{X}_3$ ,  $\text{ABX}_3$  types are taken up. Specific examples used are the fluorides, oxides and carbonates of Mg, Ca, Sr and Ba, titanates, sulfides, selenides, tellurides, iodides, etc. L. L. QUILL

**The crystal structure of solid methane.** J. C. McLENNAN AND W. G. PLUMMER. *Phil. Mag.* [7], 7, 761-74 (1929); cf. *C. A.* 23, 1029.—X-ray examn. of  $\text{CH}_4$  crystals gave close agreement between exptl. spacings and those calcd. for a face-centered cubic cell of edge 6.35 A. U. Calcn. shows 4 mols. per unit cell. The investigation confirms the conclusion that a cubic form of  $\text{CH}_4$  really exists and disproves the recently expressed view that it must be pyramidal. No evidence of the existence of a pyramidal modification was found, but its probable existence is not disputed. L. H. REYERSON

**Crystal structure of nickel films.** G. P. THOMSON. *Nature* 123, 912 (1929).—Films of Ni deposited on rock salt by spluttering, in residual gas or A, show hexagonal structure on removal from the rock salt and examn. by cathode ray diffraction. The values of the axes are:  $c = 4.06$  A. U.;  $a = 2.474$  A. U. ratio = 1.64, agreeing with the ratio 1.633 for closest packing. Ni thus resembles Co, in crystg. in both cubic and hexagonal closest packing. The calcd.  $d$  is 8.86, in agreement with that of the metal in bulk. I. J. PATTON

**Birefringence and dichroism of thin layers of iron obtained by distillation.** MARCEL CAU. *Compt. rend.* 188, 57-8, 246-9 (1929); cf. *C. A.* 22, 2705.—The previous results were confirmed on all samples. A positive rotation and positive ellipticity are obtained when the axis is parallel to the incident vibration. The dispersion in the region of the visible spectra is normal for the ellipticity and abnormal for the rotation. The effect increases when the thickness of the Fe layer increases or when the generating wire is brought closer to the film. The Faraday effect is not influenced within the limits of error by the optical effects. The effect on reflected light is the same as for the transmitted, but with the opposite sign. The formula  $E = (d/2 \sin 2A - d/2) h \sin 4A$  is derived.  $A$  = azimuth,  $d$  = relative delay suffered by the vibration parallel to the axis, and  $E$  = ellipticity. The data agree with the equation. ARTHUR FLEISCHER

**Simple method of obtaining a single crystal of zinc with approximately any desired orientation of its principal axis.** SHUVO ITO. *Mem. Coll. Sci. Kyoto Imp. Univ.* 12A, 97-105 (1929).—By welding a single crystal of Zn, with orientation of the principal axis known from the Laue photograph, to a Zn plate brought just to fusion and allowing the system to cool from the weld toward the other end a large single crystal is obtained with the principal axis oriented approx. in the same direction as the mother crystal. An asbestos-lined box is used as furnace in which welding and fusing are carried out by a Bunsen burner moved by hand. Crystals as large as 9 cm. in length, 7 cm. in breadth and

0.15 cm. in thickness were obtained. Axes other than the principal are not controlled by this method.

**Periodic and spiral forms of crystallization.** ERNEST S. HEDGES. *Nature* 123, 837-8(1929).—Crystn. in concentric rings takes place readily with benzil, benzoin, benzophenone, menthol, *m*-dinitrobenzene and acetanilide. A photograph is shown illustrating the spiral growth of crystals of  $K_2Cr_2O_7$  made by allowing a thin film of soln. to evap. on a warm microscope slide, crystn. having started from the periphery and traveled inward. The specimen of carborundum described by Menzies and Sloat (cf. C. A. 23, 4115) may have crystallized in this way.

**The relation between the lattice constant and the density of solid solutions.** SHINKITI SEKITO, *Science Repts. Tôhoku Imp. Univ.* 1st Ser. 18, 59-68(1929).—The lattice-const. of Cu solid solns. was detd. and found to follow the substitution law of Vegard. The d. of these alloys calcd. from the lattice const. agrees very well with that obtained by expt.

**New determinations of the lattice constants of potassium fluoride, cesium chloride and barium fluoride.** FINAR BROCH, IVAR OPTEDAL AND ADOLF PABST. *Z. physik. Chem., Abt. B*, 3, 209-14(1929).—Lattice const. calcd. from x-ray powder method measurements of especially purified salts were KF, 5.333 Å. U. with d. 2.5283; CsCl, 4.113 Å. U. with d. 3.9905; BaF<sub>2</sub>, 6.184 Å. U. with d. 4.8943.

**Is the lattice of tetragonal mercuric cyanide a molecular or radical lattice?** O. HASSEL. *Z. anorg. allgem. Chem.* 180, 370-3(1929); cf. C. A. 21, 1210.—Redetn. of Hg(CN)<sub>2</sub> lattice by the Bragg method checked H.'s previous work, which disagrees with Fricke and Havestadt (C. A. 22, 4019). R. FRICKE. *Ibid* 374-6.—A redetn. checked F.'s previous work. H.'s values, which check his own Bragg measurements are the mean of measurements which do not check as closely as the agreement. A. F.

**X-ray analysis of platinum deposited cathodically in the presence of helium.** R. SALVIA. *Anales soc. españ. fis. quim.* 27, 285-9(1929).—X-ray analysis of the deposit of Pt obtained by cathodic pulverization in a He atm. gave results both on the direct deposit and the fine powder. Calcn. of the planes on which selective reflection is produced shows that these planes belong to a cubic lattice with unmixed indices, characteristic of cubes centered on the faces or the characteristic structure of Pt. Calcn. shows also that taking into consideration dimensions of the elementary cube and the radius of the Pt atom, no space remains to introduce He atoms, so that it is not a matter of definite compds. of these 2 elements.

**X-ray studies on the nitrides of iron.** GUNNAR HÄGG. *Nature* 122, 962(1928); cf. C. A. 22, 4056, 4290.—All Fe-N preps. of max. N content (about 11% N) show certain split lines due to a new phase  $\eta$ . In this phase the Fe atoms form an orthorhombic lattice with the elementary dimensions  $a = 2.758$  Å. U.,  $b = 4.819$  Å. U. and  $c = 4.419$  Å. U. The limited homogeneity range of the  $\eta$ -phase indicates that it is probably Fe<sub>2</sub>N. Three Fe-N phases, therefore, exist in the concn. range now investigated; Fe<sub>2</sub>N with a cubic structure, the  $\epsilon$  phase with a hexagonal close-packed arrangement of Fe atoms, and the  $\eta$  phase. It has not been possible to det. the position of the N atom in the last two phases.

**General survey of the effects of pressure on the properties of matter.** P. W. BRIDGMAN. *Proc. Phys. Soc. (London)* 41, 341-60(1929).

**Contributions to the study of mesophases (intermediate states of aggregation).** I. The existence of mesophases. H. ZOCHER AND V. BIRSTEIN. *Z. physik. Chem., Abt. A*, 141, 413-23(1929).—Definitions are given of the terms to be employed in later papers, and the mechanical properties of the nematic and smectic mesophases are discussed. The authors point out the influence of mol. forces on the statistical uniformity in such phases, causing mol. grouping or "swarming." The possible existence of more than 2 mesophases is considered.

**The rectilinear diameter of density curves as a starting point of natural classification of pure elements or compounds.** E. MATHIAS. *Comm. Phys. Lab. Univ. Leiden*, Suppl. No. 64, 11-4(1929).—The parameter  $a$ , which characterizes the rectilinear diam., can be used to classify substances by arranging them in order of increasing values of  $a$ ; thus in homologous series  $a$  increases as mol. wt. increases.

**Comparison of nitrogen and oxygen according to the law of corresponding states.** G. P. NIJHOFF. *Comm. Phys. Lab. Univ. Leiden*, Suppl. No. 64, 49-52(1929).—Virial coeffs.,  $B$  and  $C$ , for the equation  $pv_A = A_A[1 + Bd_A + Cd_A^2 + \dots]$  are calcd. Substances with low crit. temps. have greater deviations from the law of corresponding states. O<sub>2</sub> and N<sub>2</sub> do not correspond in their deviations, contrary to results reported by other authors.

**The second virial coefficient of helium and hydrogen.** G. P. NIJHOFF. *Comm.*

*Phys. Lab. Univ. Leiden*, Suppl. No. 64, 17-27(1929).—Values are given for  $B$  in the equation  $p v_A = [A_A + B_A d_A + \dots]$  for both He and H<sub>2</sub>. Calcd. and measured values of  $B$  for H<sub>2</sub> agree at low temps., but at high temps. there are unexplained variations. Values of  $B$  for He agree more closely. E. G. VANDEN BOSCH

The measurement of gas temperatures up to 1500° in radiation fields of changing anisotropy. HERMANN SCHMIDT. *Arch. Eisenhüttenw.* 2, 293-9(1928).—Rapid changes in gas temps. are accurately measured by a resistance-heated and water-cooled gas pyrometer. A complete description and drawings are given. R. D. BUMBACHER

A new method for measuring the relative viscosity of gases and vapors. A. WEISSWEILER. *Physik. Z.* 30, 364-7(1929).—By suspending a quartz fiber in a tube sealed into a horizontal one through which a gas streams at known velocity, and measuring the deflection of the fiber by a telescope with micrometer eye-piece, the relative viscosities could be calcd. after calibrating with a gas of known viscosity. The precision is  $\pm 0.5\%$ . Full details of the app. and calibration are given. LOUIS WALDBAUR

Compressibility of carbon monoxide at 0°, at surrounding temperatures and at pressures between 50 and 130 atmospheres. SEVERIANO GOIG BOTELLA. *Anales soc. españ. fís. quim.* 27, 315-50(1929).—The compressibility of CO was detd. at pressures greater than 50 atm. at temps. of 0°, 12.44° and 20.22°, exceeding in each case the min.  $p v$  isotherm. In each isotherm values of  $p v$  and deviation coeffs. from the Boyle-Mariotte law referred to atm. pressure were obtained. The results are accurate to 0.02%. The compressibility of CO is normal; and the analogy between CO and N as regards phys. properties is confirmed. E. M. SYMMES

Microanalytical determination of vapor density. JOSEPH B. NIEDERL. *Z. anal. Chem.* 77, 169-74(1929).—The principle of the Victor Meyer and Hofmann methods is adapted to work with very small quantities of an org. substance. The app. and method of carrying out an analysis are described in detail. W. T. H

The vapor pressure of isopropyl acetate. CECIL J. HAGGERTY and JOSEPH P. WEILER. *J. Am. Chem. Soc.* 51, 1623-6(1929).—The vapor pressure of isopropyl acetate was measured over the range 0° to 90° by means of the isotenscope recommended by Smith and Menzies (*C. A.* 5, 232). The molal entropy of vaporization at the b. p. was 21.8 cal. per degree, in agreement with the value for a normal liquid. P. T. NEWSOME

The densities of coexisting liquid and gaseous nitrous oxide. ELTON L. QUINN and GRANT WERNIMONT. *J. Am. Chem. Soc.* 51, 2002-8(1929).—The d. of coexisting gaseous and liquid phases of N<sub>2</sub>O have been detd. over a temp. range from 30° to -50°. Values from 30° to 0° agree closely with those obtained by Villard over that range. The crit. d. is 0.459 and the mol. vol. at zero abs. 28.1 cc. when calcd. from Sugden's equation. N. M. BOUDER

Intensive drying of liquids. S. LENHER. *Nature* 123, 907-8(1929); cf. *C. A.* 23, 320.—The abnormal rise in b. p. observed by Baker and Smits with dried C<sub>6</sub>H<sub>6</sub> is due to superheating, since, by using their app. and procedure, similar results were obtained with ordinary C<sub>6</sub>H<sub>6</sub>. Conditioning factors are: (1) the use of a heating bath; (2) the immersion of the thermometer bulb in the liquid being investigated; (3) allowing a liquid to stand in contact with a flocculent solid; (4) distn. of the liquid into a clean flask before detg. the b. p. Repetition of Baker's work on the application of high d. c. potentials to C<sub>6</sub>H<sub>6</sub> indicates that the same source of error occurs in the rise of b. p. observed by him. I. J. PATTON

The relation of the internal pressure of fluids with some physicochemical properties. IONEL N. LONGINESCU. *Univ. of Paris. Thesis*, 108 pp.(1928); *J. chim. phys.* 26, 314-6(1929).—The force acting between mols. is represented by the expression  $K\mu/d^2$ ,  $\mu$  representing a quantity defined as the attractive mass;  $d$  is the distance. By introducing this quantity, neglecting the repulsive forces, into the classical equations for the internal pressure at the crit. temp. and pressure, an expression is derived in which  $x$  found by trial is 5.0 ( $4.5 < x < 5.5$ ). The attractive mass of a mol. is the sum of the attractive masses of its component atoms. The attractive mass of an atom depends upon its valence and chem. combination; for example, C with single, double and triple bonds has the values 0.18, 0.36 and 0.54, resp. The assocn. of a substance can be calcd. by taking the ratio of the attractive mass calcd. from exptl. data, and the ideal (non-assocd.) attractive masses calcd. by addn. of the known attractive masses of the atoms. The values calcd. for H<sub>2</sub>O, NH<sub>3</sub>, CH<sub>3</sub>OH, C<sub>2</sub>H<sub>5</sub>OH, etc., agree with Traub's values. By the use of the approx. fundamental formula  $0.360 (T_c)^{1/3} (V_c)^{1/3} = a_1 + a_2 + \dots \sum a_n$  G. G. Longinescu and Walker's empirical formulas are derived. Equations are derived for calcg.  $T_c$ , b. ps. and heats of vaporization. The values agree with exptl. values within 5%. Some new relations, such as  $T_c/p_c = A$ , proportionality between crit. values and the no. of atoms in a homologous org. series are pointed out. The mol. forces vary inversely

as the fifth power of the distance in the liquid phase, while they vary only as the fourth power in the gas phase. The difference is due to the change in the repulsive forces. For homologous nonassocd. org. series, the no. of electrons taking part in mol. attraction is equal to the square root of the total no. of electrons. The attractive mass at a const. temp. is proportional to the mol. surface. By making a comparison of external pressure (such as, the pressure of a gas) with internal pressure, L. deduces that  $P_e V$  is approx. const. *Avogadro's law* may be extended to liquids by the statement that at const. temp. two liquids at the same internal pressure have the same no. of mols. per unit vol. This gives a direct method of detg. the mol. wts. of liquids ARTHUR FLEISCHER

**Boiling points of hydrocarbons.** BORIS NEKRASOV. *Z. physik. Chem., Abt. A*, **141**, 378-86(1929); cf. *C. A.* **23**, 3390.—It was shown, on the basis of the empirical formula  $T_b = \text{const.} (M - \Sigma) / \sqrt{E}$ , (where  $T_b$  = abs. b. p.,  $M$  = mol. wt.,  $\Sigma$  = the sum of certain equiv. const. = 29.0) that the b. p. of hydrocarbons can be calcd. closely from their structural formulas. From the equivs. C = 2.00, H = 1.00 a double bond = 1.00, the b. p. of pinene calcd. to be 428° while the exptl. value is 429° abs. The formula was found to hold to within 5° for 260 out of 316 compds. LOUIS WALDBAUER

**Anomalies encountered in concentrated alcoholic solutions.** B. M. KOYALOVICH. *Zhur. Prikladnoi Khim.* **1**, 260-2(1928).—Density isotherms of mixts. of EtOH and water show a discontinuity at concs. close to 95% EtOH. V. KALICHEVSKY

**Recalculation of the densities of water-alcohol mixtures from the experimental data of Mendelyev.** A. N. GEORGIEVSKII. *Zhur. Prikladnoi Khim.* **1**, 207-19(1928).—The original data were cor. to the international H temp. scale and for the recently redtd. water. V. KALICHEVSKY

**Experimental data used by the Russian Bureau of Measures and Weights for calculating density tables of water-alcohol mixtures.** M. S. VREVSKII. *Zhur. Prikladnoi Khim.* **1**, 160-72(1928).—Exptl. data of Mendelyev are considered more accurate than those of the U. S. Bureau of Standards which are, however, close seconds and were used for mixts. contg. 0-35% EtOH and not measured by Mendelyev. For temps. below 0° exptl. data of Recknagel (*Sitzber. Bayer. Akad. Wissenschaft* 1866) are the most reliable, but more work is required for this region. V. KALICHEVSKY

**Densities of water-alcohol mixtures calculated in 1927 by the Russian Bureau of Measures and Weights.** B. M. KOYALOVICH. *Zhur. Prikladnoi Khim.* **1**, 219-60(1928).—Complete d. tables are given for the temp. range -25° - -30°. Methods used in calcg. are explained. V. KALICHEVSKY

**The density of molten metals and alloys.** YOSIHARU MATUYAMA. *Science Repts. Tohoku Imp. Univ.* 1st Ser. **18**, 19-46(1929).—The ds. of Sn, Cd, Bi, Pb and Zn and of the alloys, Sn-Cd, Sn-Bi, Bi-Pb, Sn-Zn, Bi-Cd, Cd-Pb, Cd-Zn, Sn-Bi-Cd, Bi-Cd-Pb, Sn-Bi-Pb, Sn-Cd-Pb, Sn-Cd-Zn and Cd-Pb-Zn were measured at different temps. by a method devised by the author. The expansion coeff. of molten metal is almost independent of temp., but has a slight tendency to decrease with rise of temp. The d. of molten metals at the m. p. as obtained by the extrapolation of the d.-temp. curve agrees very well with the value calcd. from the expansion coeff. of the solid metal and its change of vol. during melting. The at. vol. of molten alloys is greater than the mean of the at. vol. of the components, the amt. of the max. deviation being of the order of 1%. DOWNS SCHAAP

**Report on researches concerning the structure of substances in the solid and liquid states at low temperatures, carried out between the Fourth and the Fifth International Congress of Cold.** W. H. Keesom. *Comm. Phys. Lab. Univ. Leiden*, Suppl. No. **64**, 39-45(1929).—A report of the study, by means of x-rays, of the structure of substances which are either liquid or solid at ordinary temps. also of liquefied or solidified gases. A brief account of the work on polymorphic transformation of substances at low temps. also is given. E. G. VANDEN BOSCH

**A property of superconducting metals.** JAMES H. BARTLETT, JR. *Nature* **123**, 869-70(1929).—Polemical with Kapitza (*C. A.* **23**, 2860). Reply. P. KAPITZA. *Ibid* 870-1. J. B. AUSTIN

**Density of alkaline earth carbonates.** T. BATUECAS, A. RANCAÑO AND J. IBARZ. *Anales soc. españ. fis. quim.* **27**, 290-304(1929).—With the exception of calcite the literature on d. of alk. earth carbonates is old and inexact. The d. was detd. by pycnometer, using as counterpoise another receiver of the same shape and external vol. and as liquid pure toluene distd. over  $\text{CaCl}_2$ . Kahlbaum pptd.  $\text{CaCO}_3$  = 2.690; prepd. by igniting  $\text{CaC}_2\text{O}_4$ , purity detd. by spectroscopy, = 2.705; calcite = 2.713; aragonite = 2.929. The Kahlbaum sample was found to contain traces of Mg and was eliminated. Kahlbaum pptd.  $\text{SrCO}_3$  = 3.586; strontianite = 3.712; Kahlbaum pptd.  $\text{BaCO}_3$  = 4.290; witherite = 4.284. Except for pptd.  $\text{SrCO}_3$ , these values agree with those Wilson found

by x-ray methods. From these ds. calcn. gives for mol. vol. and contraction, resp., of aragonite 34.2, 0.55; of strontianite 39.8, 0.58; of witherite 46.1, 0.61. This shows that the contractions of alk. earth carbonates, instead of being const., as stated by Saslawsky, diminish with increase in at. wt. of the metal. E. M. SYMMES

The melting point of organic substances capable of being used as reference points at low temperatures. JEAN TIMMERMANS. *Comm. Phys. Lab. Univ. Leiden*, Suppl. No. 64, 3-8(1929).—The compds. studied were carefully prepd. and of highest purity. The compds. together with their m. ps. are:  $\text{CCl}_4$  —22.85°,  $\text{C}_6\text{H}_5\text{Cl}$  —45.35°,  $\text{CHCl}_3$  —63.5°,  $\text{EtOAc}$  —83.6°,  $\text{C}_6\text{H}_5\text{CH}_3$  —95.0°,  $\text{CS}_2$  —111.8°,  $\text{Et}_2\text{O}$  —123.3°, methylcyclohexane —126.85°, isopentane —160.0°. E. G. VANDEN BOSCHE

The molecular volume of organic components in complex salts. I. The space requirements of *o*-phenylenediamine in its compounds with metallic salts. WALTER HIEBER AND KARL RIES. *Z. anorg. allgem. Chem.* 180, 225-34(1929).—The mol. vol. of  $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$  increases in compds. with Cd salts in the order Cl, Br, I. The vol. of each mol. of diamine at 25° decreases with the no. combined with one mol. of metal salt. Ni salts are similar, except the bromide, which gives an abnormally small vol. for the  $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$ . With Co salts there is 1 exception, the vol. with 6 mols. of diamine with the chloride is greater than with 4 mols. With Zn salts the I compd. occupies less vol. than the Cl compd. In combination with sulfates the di  $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$  compds. have approx. the same vol. per mol. of diamine with Co, Ni, Cu and Zn. The vol. is less with Cd. The order of vols. is not the same with chlorides of these metals at —78° as at 25°. The min. vol. of  $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$  is estd. at about 80, a greater value than the *p*-compd. Factors influencing the vol. are the structure and kind of metal salt, and temp. Biltz' rule for ammoniates does not apply. Apparently the strength of the bond to the salt is a factor. FOSTER DRE SNELL

The form of the electrocapillary curves of soap solutions. D. TALMUD. *Kolloid-Z.* 48, 164-5(1929).—In the electrocapillary curves of solns. of K oleate in 0.1 *N* KCl soln. at concns. of 0.0003 *M* to 0.01 *M* there is observed a marked shifting of the max. In a 0.2 *M* soln. in water the shift is to the left, indicating a positive adsorption potential at the interface Hg soln. At increasing diln. the max. is shifted to the right (negative adsorption potential), and the appearance of the curves approaches that of electrolytes with an active anion. Similar results were obtained with a nonelectrolyte, *p*-toluidine, which indicates a reorientation of the mol. R. I. RUSH

Evaluation of adsorbents by thermal methods. E. V. ALEKSEVSKII. *Zhur. Prikladnoi Khim.* 1, 182-4(1928); cf. *C. A.* 20, 2609.—Animal C (*Carbo animalis purissimus* Merck) was mixed in a calorimeter with 19 org. substances and water and the temp. rises detd. The method of Berl and Andress (*C. A.* 17 1677) for estimating the relative powers of adsorbents is practical. V. KALICHEVSKY

The heat of adsorption of oxygen on charcoal. MELVILLE J. MARSHALL AND HAROLD E. BRAMSTON-COOK. *J. Am. Chem. Soc.* 51, 2019-29(1929).—The differential heat of adsorption of O on activated coconut C was measured. *Q*, the heat of adsorption per mol. of O, reached a max. of 89,600 cal. at the lowest concn. of O. The curve obtained by plotting *Q* against the concn. of O on the surface shows a tendency to flatten at 70,000 cal. and a sharp change in slope at 8000 cal. P. H. EMMETT

The influence of temperature upon the adsorption of gases. H. ZEISE. *Z. physik. Chem.*, Abt. A, 138, 289-99(1928).—The values of  $c_1$  and  $c_2$  in Langmuir's equation are functions of the temp. although not so indicated by the equation. Z. shows that the influence of the temp. upon  $c_1$  may be expressed by  $c_1 = a_1 - b_1T$  and upon  $c_2$  by  $c_2 = 10^{a_2/T^{b_2}}$ , wherein  $a$ ,  $b$ ,  $a_2$  and  $b_2$  are the neg. direction coeffs. in the system with the coordinates  $c_1$ ,  $T$  and  $\log c_2$ ,  $\log T$ , resp. EMIL KLARMANN

A case of reversal of adsorption. H. FREUNDLICH AND L. L. BURGESS. *Z. Elektrochem.* 35, 362-6(1929).—PbS, pptd. by the interaction of  $\text{Pb}(\text{OAc})_2$  and  $\text{Na}_2\text{S}$  under proper conditions will change its sp. surface as time progresses. A basic dye like rhodulin violet and an acid dye like fast acid violet, which are initially highly adsorbed from soln., are returned to the soln. This desorption takes place autocatalytically. The rate of desorption in the case of the true-acid violet was but slightly dependent on the dye concn., rapidity of stirring and temp. and thus the rate of crystn. of the PbS was measured. The rapidity of desorption in this case was greater than in the case of the rhodulin violet, which is explained by Marc's statement that a more highly adsorbed substance impedes the rate of crystn. more than a weakly adsorbed one. In older expts. on desorption, e. g., with HgS and S and basic dyes, not only the rate of crystn. but also the rate of pptn. of the sol was measured. I. J. PATTON

The adsorption of electrolytes by crystalline surfaces. II. L. DE BROUCKÈRE. *Bull. sci. acad. roy. Belg.* [5], 15, 170-82; *J. chim. phys.* 26, 250-75(1929); cf. *C. A.* 22,

2092; 23, 751.—The previous method of detg. the isotherm was applied to  $\text{CdCl}_2$ ,  $\text{HgCl}_2$ ,  $\text{LaCl}_3$  and  $\text{PbCl}_2$ . A new sample of  $\text{BaSO}_4$  was prepd. of which 1.41 g. was equal to 1 g. of the previous prepn. As previously found, the adsorption equil. was reached by either increasing or decreasing the concn. of the electrolyte. Capillary effects were too small to cause errors. Anions and cations are adsorbed in equiv. quantities. At satn., the isotherms are arranged with decreasing adsorption with increasing at. wt. The results for bivalent chlorides are in accord with a unimol. layer. Also in *Bull. soc. chim. belg.* 38, 212-22(1929). A. F.

**Adsorption of ions and the physical character of precipitates.** HARRY B. WEISER AND G. E. CUNNINGHAM. *Colloid Symposium Monograph* 6, 319-41(1928); *J. Phys. Chem.* 33, 301-16(1929).—Factors other than percentage supersatn. which influence the phys. character of ppts. are the sp. tendency of particles to adsorb the solvent, the shape of the particles and the effect of adsorbed ions. The phys. character of pptd. S varies more or less continuously from gelatinous and reversible to plastic and completely non-reversible when thrown down in the presence of the lyotropic series of ions from Li to Cs and from Mg to Ba. Ultramicroscopic observations of the change taking place when a highly hydrated cation is removed from a gelatinous S clump by displacing with a less hydrated, more strongly adsorbed cation, shows a very marked shrinkage as the result of the loss of adsorbed  $\text{H}_2\text{O}$  and the coalescence of the particles. Motion pictures were made of the process. A reversible ppt. of any substance will be obtained when a sol is neutralized under such conditions as to prevent coalescence (a) by the intervention of a film of adsorbed solvent or (b) by preventing collision of the neutralized particles. In either case the adsorption of the neutralizing ion must be sufficiently weak to permit its removal by washing. The fundamental nature of pptd. S clumps depends upon whether or not the conditions under which pptn. is carried out favor the coalescence of the ultra-microns, which in turn depends upon the nature and hydration of the adsorbed ions. H. B. WEISER

**Brownian movement apparatus.** HARRY C. DOANE AND WM. A. DOW. *J. Chem. Education* 6, 1099(1929).—A beam of light is projected just below the surface of a colloidal soln. of  $\text{As}_2\text{S}_3$ . The Brownian movement is observed against a dark field by a microscope at 100  $\times$  magnification. The soln. is prepd. by adding a satd. soln. of  $\text{H}_2\text{S}$  drop by drop to a dil. soln. of  $\text{H}_3\text{AsO}_3$  till, by shaking, a slight yellow color appears. The  $\text{H}_3\text{AsO}_3$  is prepd. by refluxing 2 g.  $\text{As}_2\text{O}_3$  with 100 cc. distd.  $\text{H}_2\text{O}$  till dissolved, then dilg. with 9 vols. distd.  $\text{H}_2\text{O}$ . C. Z. ROSECRANS

**Changes in physicochemical properties in the transition region between colloidal and molecular dispersed systems. I.** WO. OSTWALD AND ALFRED QUAST. *Kolloid-Z.* 48, 83-95(1929).—Diffusion coeffs. of purified dyestuffs in alc.-water mixts. of varying compn. were detd. by the method of Auerbach. From these the relative particle size was calcd. according to A. Einstein. All dyestuffs examd. (night blue, crystal violet, Congo red, benzopurpurin, Nerol, sulfocyanine, new fuchsin, brilliant green) showed a max. degree of dispersion in a mixt. contg. 40-60% alc. The radii calcd. according to Einstein varied in the ratio 1:100, depending upon the compn. of the dispersion medium. II. *Ibid* 156-64.—B.-p. elevations of night blue and crystal violet in  $\text{H}_2\text{O}$ -alc. mixts. show a max. particle size in 40-60% alc. The surface tension of water-alc. mixts. after addn. of these dyestuffs is practically independent of the compn. of the mixt., except at high water concns. A min. sp. viscosity and max. foaming are observed in the intermediate region of water-alc. mixts. contg. these dyestuffs. FRANK URBAN

**The theory of the change in charge of colloidal particles.** A. EUCKEN. *Z. physik. Chem., Abt. B*, 1, 375-8(1928).—The change in charge of colloidal particles on adding electrolytes to sols is explained by the aid of the Debye theory of strong electrolytes instead of by the assumption of selective adsorption of ions. The Debye-ion atmosphere runs parallel with the elec. double layer which exists at a solid-liquid interface, e. g., the surface of colloidal particles. Changing the ion atmosphere changes the distribution of the charge on the double layer, thereby altering the charge on the colloidal particles. HARRY B. WEISER

**Cataphoresis of lead sulfate.** EUGENE L. JEWETT. *J. Phys. Chem.* 33, 1024-6(1929).—Cataphoresis expts. show colloidal  $\text{PbSO}_4$  to be positively or negatively charged depending upon the method of prepn. When  $\text{H}_2\text{SO}_4$  is electrolyzed between Pb plates,  $\text{PbSO}_4$  is formed and held to the plate more strongly by cataphoresis than by adsorption. The use of a. c., causes pptn. of  $\text{PbSO}_4$  at each electrode. Slow reversal of the current minimizes the cataphoretic effect and increases that of adsorption. Cataphoresis may explain the theory of the electrolytic prepn. of insol. salts and the detn. of Pb. F. W. LAIRD

**Plastometric studies of the formation of boundary layers.** A. DE WAELE AND G.

L. LEWIS. *Kolloid-Z.* 43, 126-41(1929).—Plastometric studies were made of carbon black in oxidized linseed oil, in mineral oil with and without added polar mineral oil, of violet lake in oxidized linseed oil and in mineral oil, of wool grease-water emulsions, mineral oil-dil. sulfonated oil emulsions, aq. suspensions of china clay and bentonite suspensions of ultramarine in blown rapeseed oil, and nitrocellulose in AcOAm. The existence of a pseudo-solid or "bound" layer enveloping the dispersed particles of such systems is shown. The calcd. ratio of the thickness of this boundary layer to the av. radius of the dispersed particles may be used for characterizing a colloidal system. It is closely related to the plastic flow and the general colloidal properties. The value for the ratio depends on the size of the dispersed particles, is inversely proportional to the degree of dispersion and is const. for a given solid-liquid system over a wide range of concns. The viscosity of the liquid directly adjacent to the "bound" layer of liquid is very great. If a solid dispersing agent is added to a liquid contg. a dispersed material, the dispersing agent is adsorbed on the surface of the particles already present. From a thermodynamic point of view, the plastic flow of solid-liquid and liquid-liquid systems is not directly related to the lyotropic state, or the formation of a pseudo-solid layer.

CORNELIA T. SNELL

Peptization of dyestuffs by neutral salts. WO. OSTWALD. *Ber.* 62B, 1194-6 (1929).—Free Congo red dye acid may be rendered sol. in water by addn. of 0.5 N KCl or  $MgCl_2$ . A blue Congo acid sol turns red upon addn. of neutral chlorides, iodides, bromides, chlorates, nitrates, sulfates, etc., of univalent and multivalent cations. Flocculation takes place at higher concns. Ammonium salts, however, cause a bathochromic color displacement. Absorption curves were detd. before and after addn. of NaCl. These show the enormous hypsochromic displacement of the absorption max. F. U.

The flocculation of colloidal solutions. A. BOUTARIC. *J. pharm. chim.* 7, 395-401, 456-67(1928).—A comprehensive résumé. Cf. *C. A.* 19, 2291, 2292, 2767; 20, 3257; 22, 3080; 23, 1040.

S. WALDBOTT

The flocculation of hydrosols of gold. A. BOUTARIC AND Mlle. M. DUPIN. *Bull. soc. chim.* 45, 28-9(1929).—When the time required for flocculation of an  $As_2S_3$  sol. or a  $Fe(OH)_3$  sol is plotted against the quantity of coagulating electrolyte added, the graph asymptotically approaches a line representing the min. concn. of electrolyte which will produce flocculation. In the case of a Au hydrosol, there are three significant concns. of multivalent electrolyte such as  $AlCl_3$ ,  $FeCl_3$  and Th chloride, *a*, *b* and *c*. Concns. of electrolytes between *a* and *b* produce red gelatinous flocculations. Concns. between *b* and *c* produce a change of charge on the colloid. Concns. above *c* produce blue granular particles which are positively charged.

F. E. BROWN

Oxidation of colloidal sulfides of arsenic, antimony and copper. M. SWIDER-KA, W. KOSTANECKA AND P. WARSZAWSKA. *Roczniki Chem.* 9, 411-6(416-7 German)(1929).—The oxidation of  $As_2S_3$ ,  $Sb_2S_3$  and CuS in colloidal soln. by air was measured. After prolonged action of air  $As_2S_3$  gives  $H_3AsO_3$ ,  $H_2SO_4$  and free S. After the oxidation of  $Sb_2S_3$  with air, only  $H_2SO_4$  is found in the filtrate; no S is in the ppt. of unchanged  $Sb_2S_3$ . In the presence of  $H_2S$  CuS gives only free S, the amt. of which increases with the time of the action of air. Only after all  $H_2S$  has been expelled from the soln. do Cu ions appear in the filtrate. The free oxidation of sulfides renders all detns. doubtful when they are performed in the presence of air with considerable amts. of colloidal sulfides, particularly of  $As_2S_3$ .

J. KUČERA

Colloidal sulfur. M. LORA Y TAMAYO. *Anales soc. españ. fís. quím. (sec. tercia)* 27, 110-2(1929).—S hydrosol of sufficient stability to be used for injection is obtained by pouring 100 cc. of a hot soln. of S in alc. gradually into 100 cc. of a 1% aq. gelatin soln. prepd. according to Wo. Ostwald. The mixt. is then heated under reduced pressure to remove half the alc. The hydrosol does not deposit within 7 days, and after that agitation is sufficient to disperse it again.

E. M. SYMMES

Formations obtained by desiccation of colloidal solutions of alumina and chromium oxide. PAUL BARY AND JOSÉ V. RUBIO. *Anales soc. españ. fís. quím.* 27, 273-84 (1929).—Attempts were made to reproduce with  $Al_2O_3$  and  $Cr_2O_3$  the same phenomena noted previously with  $Fe_2O_3$  (*C. A.* 22, 3080). Results obtained confirmed the former, but were less pronounced. It is concluded that metallic sesquioxides in soln. are formed of a mixt. of 2 oxides of like compn. but unequally hydrated, 1 being a hydrophilic suspension of the other, protecting it. Aging of colloidal solns. of this type causes slow transformation of the hydrophilic to the hydrophobe colloid. Formations obtained on glass by desiccation of solns. cannot in this case be explained by the Weimarn theory.

E. M. SYMMES

Jellies and gels. F. KIRCHHOF. *Kautschuk* 5, 100-3, 140-2(1929).—A review. C. C. DAVIS

**Calcium acetate gels.** I. P. C. L. THORNE AND C. G. SMITH. *Kolloid-Z.* **48**, 113-25(1929).—By pouring varying amts. of a satd. soln. of anhyd.  $\text{Ca}(\text{OAc})_2$  into 95% alc., gelatinous ppts. and gels may be obtained. The characteristics of these gels depend on the salt concn. and on the total  $\text{H}_2\text{O}$  content of the mixt. If the latter is 12% or more, sols and not gels, are formed. The viscosity of the sols reaches a max. when the acetate soln. is 50% of the total vol. No sharp change in viscosity occurs with a change from sol to gel. The stability of the gels varies from a few hrs. to a few days, after which they gradually soften and  $(\text{AcO})_2\text{Ca}$  ppts. in small clusters. If the gel contains much  $\text{H}_2\text{O}$ , needle-like crystals radiate from the nuclei. The addn. of  $\text{Me}_2\text{O}$ , glycerol, Na, K or Fe oleate, stearin or oleic acid, stabilizes the gels for periods up to 6 months. The fibrous structure of these gels may be seen with the naked eye. The addn. of Na oleate causes syneresis. Gels contg. K or ferric oleate shrink slowly. Materials such as  $\text{CHCl}_3$  and  $\text{CCl}_4$  have little influence on the stability. Acids and alkalis cause the gels to set more slowly and shorten the period of stability. Salts vary in their effects; bivalent cations retard the speed of gel formation more than univalent cations. The temp. of prepn. does not affect the stability of the gels. The gel retains its form for a long time on drying, becoming more and more turbid. The alc. evaps., and after 4-6 weeks, the  $(\text{AcO})_2\text{Ca}$  dissolves in the remaining  $\text{H}_2\text{O}$ . CORNELIA T. SNELL

The thixotropy of dispersions of low concentration. E. A. HAUSER. *Kolloid-Z.* **48**, 57-62(1929).—The term thixotropy, first used by Peterfi, refers to an isothermal, reversible gel-sol transformation by means of shaking or other mechanical influences. The thixotropy of a bentonite (aluminum silicate) dispersion depends on the diam. of the container, as well as on the concn. of the dispersed substance. Thixotropic properties of native bentonite disappeared after dialysis, but could be restored by addn. of electrolytes. Ultramicroscopic examn. of dialyzed bentonite dispersions of low concn. showed that addn. of electrolytes first removed the translational, next the rotational component of Brownian motion. Further addn. caused aggregation and coagulation. Thixotropic  $\text{Fe}_2\text{O}_3$  sols also were studied, as well as the influence of other colloidal dispersions on thixotropic sols. An attempt is made to explain thixotropy by hydration, and orientation of the mols. of the dispersion medium. FRANK URBAN

Studies on adsorption and swelling. V. KUBELKA AND J. WAGNER. *Cuir tech.* **17**, 514 20(1928); cf. *C. A.* **23**, 1038. J. G. NIEDERCORN

The combination of gelatin with hydrochloric acid. II. New determinations of the isoelectric point and combining capacity of a purified gelatin. DAVID I. HITCHCOCK. *J. Gen. Physiol.* **12**, 495-509(1929); cf. *C. A.* **16**, 3672; **17**, 1252, 3682; **18**, 696—A com. gelatin purified according to Northrop and Kunitz (*C. A.* **22**, 2699), and isoelec. at  $\text{pH}$  5.05 as detd. from osmotic pressure and max. opacity measurements, was used in these expts. From H-electrode measurements with KCl-agar junctions, coned. titrations and e. m. f. measurements with the cell  $\text{Ag}, \text{AgCl}, \text{HCl} + \text{gelatin}, \text{H}_2$ , without liquid junction, it is concluded that this gelatin combines with approx.  $9.4 \times 10^{-4}$  equivs. of  $\text{H}^+$  and  $1.7 \times 10^{-4}$  equivs. of  $\text{Cl}^-$  per g. gelatin. C. H. RICHARDSON

The change of surface tension of gelatin with changing  $\text{pH}$  and at low electrolyte concentrations. N. YERMOLENKO. *Kolloid-Z.* **48**, 141-6(1929).—The surface tension of 0.1% gelatin sol showed a min. at  $\text{pH}$  4.7 and max. at  $\text{pH}$  2.85 and at 8.3. The  $\text{pH}$  was detd. colorimetrically. The gelatin contained 0.83% ash. At electrolyte concns. of less than  $10^{-12}$  N no influence on the properties of the reversible colloid was noticed. FRANK URBAN

The structure of gelatin solutions. N. MARINESCO. *Compt. rend.* **188**, 1163-5 (1929); cf. *C. A.* **23**, 3614.—The sp. inductive capacity of aq. solns. of gelatin increases rapidly and linearly as the concn. increases until a sharp max. is reached at dielec. const. 108 and concn. 0.6%, after which it falls off sharply again. The max. coincides with the min. concn. at which gelation is possible. At concns. below this critical point the solns. are optically empty, do not exhibit viscosimetric rigidity, and are powerful protective agents for hydrophobe colloids. It is concluded that gelatin mols. are very highly polar—more so than  $\text{H}_2\text{O}$  mols.—and that below 0.6% concn. they exist in soln. as single mols. Above 0.6% concn. the gelatin mols. unite in aggregates having zero elec. moment. F. L. BROWNE

Orientation and pseudo crystallization resulting from the action of traction in colloidal gels. JEAN J. TRILLAT. *Compt. rend.* **188**, 1246-8(1929).—Films of cellulose nitrates and acetates were subjected to traction by stretching them in one direction and the resulting changes in x-ray patterns observed. The unstretched films showed the halos characteristic of amorphous material. Stretching gave rise to patterns which prove that the long chain-like mols. become oriented parallel to the direction of stretch-

ing. The effect increased as the stretching was increased. Eventually a pseudo cryst. state was reached in which there still remained some residual amorphous material.

F. L. BROWN

**The formation of the secondary system of Liesegang's layers.** II. M. S. DUNIN AND F. M. SHEMYAKIN. *Kolloid-Z.* **48**, 167-70(1929); cf. *C. A.* **21**, 1738-9.—A tube of gelatin gel to which a soln. of  $\text{AgNO}_3$  was added was allowed to stand in a dark room for about a year and a half. Five supermacroscopic layers were observed, the width of the layers and the space between being alternately large and small. Also 5 supermacroscopic layers of  $\text{Ag}_2\text{Cr}_2\text{O}_7$  and 9 of  $\text{PbI}_2$  were obtained, and the phenomenon of complex periodicity is plainly recognized. Microscopic layers of  $\text{Ag}_2\text{Cr}_2\text{O}_7$  and  $\text{Ag}_3\text{PO}_4$ ,  $\text{Ca}_3(\text{PO}_4)_2$ ,  $\text{PbI}_2$  and  $\text{Cu}_2\text{Fe}(\text{CN})_6$  cyanide have the same appearance and obviously are united to form macroscopic layers. In the case of  $\text{Ag}_3\text{PO}_4$  and also of  $\text{PbI}_2$  microscopic, macroscopic, and supermacroscopic layers were observed. The transition of layers of one class into another is possible through a series of external factors. It is postulated that there are three concns. corresponding to the formation of the three kinds of rings. The analogy between the phenomenon of complex periodicity and the so called "zones of silence" or "death zones" is pointed out.

R. I. RUSH

**Studies on permeability of membranes.** VII. Conductivity of electrolytes within the membrane. ARDA A. GREEN, A. A. WEECH AND L. MICHAELIS. *J. Gen. Physiol.* **12**, 473-85(1929); cf. *C. A.* **23**, 1655.—The elec. cond. of dried collodion membranes in contact with electrolyte solns. of various concns. was measured by two methods. Each membrane with each electrolyte showed a max. level of resistance at a certain electrolyte concn. which was probably detd. by the collodion rather than by the electrolyte soln. In relatively concd. solns., cond. was approx. proportional to concn. With different electrolytes at the same concn. conductivities varied much more than in simple solns. without a membrane and followed the order  $\text{HCl} > \text{KCl} > \text{NaCl} > \text{LiCl}$ . A membrane satd. with either  $\text{HCl}$  or  $\text{KCl}$  (0.5 *N*) had nearly the same total content of electrolyte, whereas the same membrane in contact with  $\text{LiCl}$  contained only one-half the quantity. Two factors probably cause the divergent conductivities obtained with different electrolytes: (1) the quantity of electrolyte that can enter the pores of the membrane which depends upon pore size and the vol. of the larger of the two hydrated ions of the electrolyte; (2) differences in the mobility of the various cations within the membrane due to friction between ions and pore walls. The difference in cond. between  $\text{KCl}$  and  $\text{LiCl}$  is largely detd. by (1); that between  $\text{KCl}$  and  $\text{HCl}$  is explained by (2). A method for detg. the electrolyte content of a membrane in contact with different chloride solns. is described. VIII. The behavior of the dried collodion membrane toward bivalent cations. A. A. WEECH AND L. MICHAELIS. *Ibid* 487-93(1929).—A study of the behavior of dried collodion membranes toward  $\text{Ca}$  ion shows: (1) that a p. d. is not established across a membrane sepg. two  $\text{CaCl}_2$  solns. of 0.1 and 0.01 *N* concns.; (2) that the transfer nos. of  $\text{Cl}^-$  and  $\text{Ca}^{2+}$  are both approx. 0.5; (3) that the membrane in equil. with a soln. of  $\text{CaCl}_2$  has an elec. resistance which is much higher than is produced by solns. of any of the univalent chlorides; (4) that the total electrolyte content of a membrane in equil. with  $\text{CaCl}_2$  soln. was only 20% of that obtained with  $\text{LiCl}$  soln. and 10% of that for  $\text{KCl}$  soln. These results are probably due to the inability of the  $\text{Ca}$  ion to penetrate any but the largest of the pores in the collodion membrane.

C. H. R

**The permeability of dry collodion membranes.** II. JOHN H. NORTHRUP. *J. Gen. Physiol.* **12**, 435-61(1929); cf. *C. A.* **22**, 1513.—The rates of penetration and solubilities of  $\text{H}_2\text{O}$ ,  $\text{N}$ ,  $\text{NH}_3$ ,  $\text{H}_2\text{O}$ ,  $\text{HCl}$  gas,  $\text{CO}_2$ ,  $\text{HCOOH}$ ,  $\text{AcOH}$ ,  $\text{CH}_2\text{ClCOOH}$ ,  $\text{CHCl}_2\text{COOH}$ , glycerol,  $\text{C}_6\text{H}_5\text{OH}$  and  $\text{HgCl}_2$  in dry collodion membranes were measured. The rate of penetration of  $\text{H}$  and  $\text{CO}_2$  is the same whether the gas passes through the dry membrane or whether the membrane is immersed in water. The soly. of  $\text{CO}_2$ ,  $\text{AcOH}$ ,  $\text{C}_6\text{H}_5\text{OH}$  and water in collodion is reversible and proportional to the concn. or vapor pressure in low concns. and independent of the surface of the collodion. The results obtained by calcn. of pore size from the vapor pressure of water and from the rate of flow of water through the membrane do not agree and are not consistent with the observed rates of penetration. The rates of penetration bear no relation to the density of the gas. When the results are expressed as diffusion coeffs. in collodion they show that the diffusion coeff. increases rapidly with the decrease in mol. wt.

C. H. RICHARDSON

**An explanation of the "electrocapillary" Becquerel phenomenon.** H. FREUNDLICH AND K. SÖLLNER. *Z. physik. Chem.*, Abt. A, **138**, 349-56(1928).—Becquerel's phenomenon depends upon the pptn. of metal on a porous membrane sepg. the soln. of a metal salt from the soln. of another salt which forms an insol. ppt. with it; the metal is always deposited on the side which faces the soln. of the metal salt. F. and K. find that this phenomenon is observed only when the insol. ppt. deposited in the pores of the membrane

is capable of "metallic" or at least "semimetallic" cond. Moreover the potential of the concn. chain between the soln. of the metal salt which contains the high concn. of metal ions and the other soln. with a very low concn. must be greater than the decompn. voltage required to deposit the metal. While in Becquerel's work the soln. of the metal salt was allowed to react with a  $\text{Na}_2\text{S}$  soln., even better results are obtained with  $\text{Na}_2\text{Se}$ . In systems such as  $\text{AgNO}_3\text{--KOH}$  or  $\text{CuSO}_4\text{--KOH}$  the metal is deposited only upon addn. of an anodic depolarizer which is capable of lowering the decompn. voltage sufficiently. No deposition of metal occurs in the system  $\text{CuSO}_4\text{--K}_4\text{Fe}(\text{CN})_6$ ; this is explained by the fact that the ppt. of  $\text{Cu}_2\text{Fe}(\text{CN})_6$  does not show the property of "metallic" cond.

EMIL KLARMANN

**Flotation and  $p_H$ .** I. Flotation ability of hydrophobe powders and  $p_H$ . D. TALMUD. *Kolloid-Z.* 48, 165-6(1929).—The flotation of electrode C is detd. at various  $p_H$  values, with the standard buffer solns. of Sørensen (borate citrate and phosphate) to control the  $p_H$ , and purified kerosene and benzene as the flotation reagents. A max. is obtained near the neutral region. Very slight impurities in the reagents change the form of the curve completely. Similar results were obtained with S crystals. In the case of S flowers the relation is complicated by the oxidation of S. These results seem to substantiate the theory that there is a potential difference at the interface hydrophobe powder-soln. whose magnitude depends on the  $p_H$  of the soln. R. I. RUSH

**Radioactive methods in physical chemistry.** J. EßTERMANN. *Z. Elektrochem.* 35, 368-73(1929).—A brief summary of the use of radioactive elements in measurements of soly., diffusion, ionic phenomena, etc.

I. J. PATTON

**Solubility in a mixture of solvents.** II. The solubility of a substance which is miscible in all proportions with one of the solvents. F. ANGELESCU. *Z. physik. Chem.*, Abt. A, 138, 300-10(1928); cf. *C.* 4, 22, 1885.—The equation  $S_0 - S_\infty = KC^p$  which was previously derived holds also in this case where the dissolved substance (PhOH) is miscible with one of the components of the system dihydroxybenzene- $\text{H}_2\text{O}$ . Resorcinol, pyrocatechol and quinol were used.

EMIL KLARMANN

**Solubility of calcium carbonate (calcite) in certain aqueous solutions at 25°.** G. L. FREAR and JOHN JOHNSTON. *J. Am. Chem. Soc.* 51, 2082-93(1929).—Data are given for the soly. of  $\text{CaCO}_3$  in  $\text{H}_2\text{O}$  at 25° under partial pressure of  $\text{CO}_2$  from 0.00032 to 10 atm. The relation between  $r$  (the ratio of the soly. at  $t^\circ$  to that at 25°) and  $T$  is  $\log r = 830/T - 2.78$ . Data for soly. of solns. satd. with both  $\text{CaCO}_3$  and  $\text{CaSO}_4$  are given for partial pressures of  $\text{CO}_2$  from 0.121 to 0.962 atm. The soly. of  $\text{CaCO}_3$  in  $\text{NaCl}$  solns. is given for  $\text{CO}_2$  pressures from 0.965 to 0.968 atm. The soly. product const. of calcite at 25° in terms of the activities is  $4.8 \times 10^{-9}$ . No indications were found of a change in the nature of the solid phases  $\text{CaCO}_3$  and  $\text{CaSO}_4$ . Activity coeffs. of  $\text{Ca}(\text{HCO}_3)_2$  were calcd. from soly. measurements.

A. J. MONACK

**Solubility of magnesium carbonate (nesquehonite) in water at 25° and pressures of carbon dioxide up to one atmosphere.** WALTER D. KLINE. *J. Am. Chem. Soc.* 51, 2093-7(1929).—The methods of Walker, Bray and Johnston (*C.* 21, 2214) were employed. Data are given for the observed mean molalities of solns. in equil. with a series of pressures of  $\text{CO}_2$  at 25° ranging from 0.000107 atm. to 0.9684 atm.

A. J. M.

**The solubility of ammonium bicarbonate in water up to the melting point.** E. JÄNECKE. *Z. Elektrochem.* 35, 332-4(1929).—To avoid decompn. of the salt the soly. was detd. by placing known mixts. of salt and water in a sealed tube in a thermostat with suitable slaking. The temp. at which the last trace of salt disappeared was detd. Values are given for the cryohydric point,  $-3.9^\circ$ , to the m. p.,  $107.5^\circ$ . At lower temps. agreement with previously published results is excellent but differences of almost 100% from values (extrapolated) of Terres and Weiser appear at  $100^\circ$ .

H. G. W.

**The mutual salting-out of ions.** J. A. V. BUTLER. *J. Phys. Chem.* 33, 1015-23 (1929).—The effect of the forces exerted by the elec. field of an ion on the solvent molts., on the distribution of other ions in its vicinity, is discussed. An expression for the salting-out of substances by electrolytes is developed and shown to be equiv. to that obtained by Debye and McCauley on a different basis. The result is applied to the mutual salting-out of ions. The effect may be of prime importance in detg.  $B$  in the equation  $\log f = -A\sqrt{\mu} + B\mu$ .

**Exceptional mobility of the hydrogen and hydroxyl ions in aqueous solutions.** M. S. SKANAVI-GRIGOR'YEVA. *Z. anorg. allgem. Chem.* 181, 337-46(1929).—See *C.* A. 23, 3843.

E. J. C.

**The measurement of change in volume on solution.** E. ROGER WASHBURN. *J. Chem. Education* 6, 1144-6(1929).—An expt. that has proved of value with students of elementary phys. chem., requiring about 3-4 hrs. for completion, is described. A series of solns. is prepd. contg. the same components in different proportions, the change

in vol. noted, brought to room or thermostat temp., the ds. detd. and the change in vol. calcd. from the original vols. and the measured ds. by (a) change in d., (b) change in vol. or (c) on the basis of sp. vol. Results are plotted.

W. C. EBAUGH

The transportation of carbon dioxide by paraffin oil and some other substances. SAMUEL E. HILL. *Proc. Soc. Exptl. Biol. Med.* 26, 590-2(1929).—The time in hrs. required for 1 atm. of  $\text{CO}_2$  to diffuse through the test substance and decolorize 1 cm. of phenolphthalein in NaOH agar was used for comparison. The passage of  $\text{CO}_2$  through lighter paraffin oils is greatly decreased by preventing convection currents. This was accomplished by placing disks of blotting paper or tightly packed cotton in the oil layer. Substances found impermeable or relatively so to  $\text{O}_2$  were also impermeable to  $\text{CO}_2$ ; the most striking differences were with rubber and dry collodion, through which  $\text{O}_2$  passes with difficulty and  $\text{CO}_2$  with the greatest ease.

C. V. BAILEY

Cryoscopic determination of the molecular equilibria of resorcinol in aqueous solutions of sodium chloride. F. BOURION AND CH. TURTLE. *Compt. rend.* 188, 1496-8 (1929); cf. *C. A.* 22, 3337; 23, 3395.—The equil. const. for the change  $n \text{ C}_6\text{H}_3\text{O}_2 \rightleftharpoons (\text{C}_6\text{H}_3\text{O}_2)_n$  in NaCl solns. was studied. In the NaCl solns. studied  $n = 2$  up to 0.6 M in resorcinol and  $n = 3$  from 0.9 to 2.0 M. In 0.5 M solns. of NaCl the equil. const.  $K_2 = 0.98$ ,  $K_3 = 1.63$ . In 1.225 M solns.  $K_2 = 1.05$  and  $K_3 = 1.50$ . The cryoscopic const. for water is 18.4 for 0.5 M solns. of NaCl, 23.4, for 1.225 M solns., 28.0. It is less for KCl. The assocn. of resorcinol is more marked in chloride solns. than in water. By thermodynamic reasoning alkali chloride solns. should have cryoscopic consts. about the same as water. The divergence is explained by assuming adsorption of water by the salt. The degree of this hydration was calcd. and found to be between 11 and 23 mols. of water per mol. of alkali chloride. Also in *J. chim. phys.* 26, 291-311(1929).

A. C. HIGGINS

Ebullioscopic determination of the molecular equilibrium of resorcinol in solutions of lithium chloride. F. BOURION AND E. ROUYER. *Compt. rend.* 188, 626-8(1929); cf. *C. A.* 22, 1082, 1712.—In aq. LiCl solns., there is an equil. between single and triple resorcinol mols. at concns. below 1.75 M. In solns. above 1.75 M in resorcinol the equil. is between single and quadruple mols. There are differences between consts. found in solns. of KCl, of NaCl and of LiCl which can be explained by assuming that the ions of these alkali metals are unequally hydrated and that the hydration varies in the same order as the ionic activities.

F. E. BROWN

Newer conceptions of electrolytes. NIELS BJERRUM. *Ber.* 62B, 1091-1103 (1929).—An address.

FRANK URBAN

Law of equilibrium of electrolytes and hydration of ions. K. JABLONCZYŃSKI AND C. SEIDENGART. *Roczniki Chem.* 9, 418-30(430 French)(1929).—Cryoscopic measurements were made with KCl,  $\text{NH}_4\text{Cl}$ , NaCl, LiCl and HCl separately and then with their mixts. The mol. wts. of urea and mannitol were detd. by the cryoscopic method in the solns. of the same electrolytes having various concns. The exptl. results permit complete verification of the equation of equil. established by Jablonczyński and Wisniewski (*C. A.* 23, 3390) as well as the hydration of the ions.

JAROSLAV KUČERA

The number of water and alcohol molecules bound to the silver ion. GERHARD C. SCHMIDT AND MECHTILD KELLER. *Z. physik. Chem., Abt. A*, 141, 331-42(1929).—On the addn. of  $\text{NH}_3$  or  $\text{C}_6\text{H}_5\text{N}$  to  $\text{AgNO}_3$  soln., the complex ions  $\text{Ag}(\text{NH}_3)_2$  and  $\text{Ag}(\text{C}_6\text{H}_5\text{N})_2$  are formed; these are more stable in MeOH than in  $\text{H}_2\text{O}$ . It seems probable that these ions are not hydrated. From the change in transference velocity of the Ag ion on the addn. of  $\text{NH}_3$  and of  $\text{C}_6\text{H}_5\text{N}$ , the authors conclude that two mols. of solvent are combined with the Ag ion. In aq. soln. an equil. exists between  $\text{Ag}$ ,  $\text{Ag}(\text{H}_2\text{O})$  and  $\text{Ag}(\text{H}_2\text{O})_2$  ions, and an analogous one exists in alc. solns.

V. E. B.

**The use of decinormal hydrochloric acid for standardizing electrometric  $p_H$  measurements.** NOEL F. MACLAGAN. *Biochem. J.* 23, 309-18(1929).—Some of the factors influencing the p. d. at the liquid junction 0.1 N HCl | satd. KCl were investigated and a method of forming the junction, as well as a new type of flowing junction, is described.

**Polarographic studies with the dropping mercuric cathode.** I. The amphoteric nature of ferrous hydroxide. B. SCHRAGER. *Collection Czechoslov. Chem. Comm.* 1, 275-81; *Chem. News* 138, 354-6(1929); cf. *C. A.* 19, 2905.—By the polarograph, previously described, the alkali hydroxides have been found to dissolve  $Fe(OH)_2$  according to the equation  $Fe(OH)_2 + OH^- \longrightarrow Fe(OH)_3^-$ . In N soln. this is  $5 \times 10^{-8}$  g. equiv. per l. The deposition of iron occurs at  $-1.50$  volts from the calomel electrode.  $[Fe^{++}][OH^-]^2 = 7 \times 10^{-18}$  and  $[Fe(OH)_3^-] + [OH^-] = 5 \times 10^{-8}$  and  $[Fe(OH)_3^-] + [Fe^{++}][OH^-]^2 = 7 \times 10^{-17}$ . Cobalt and manganese behave similarly. V. F. H.

**Volume changes during neutralization.** I. I. ZASLAVSKII, E. G. STANDEL AND V. V. TOVAROV. *Z. anorg. allgem. Chem.* 180, 241-51(1929).—The vol. changes during neutralization have been measured at various concns. for the following systems: KOH - HOAc, NaOH - HOAc, NaOH - HNO<sub>3</sub>, NH<sub>3</sub> - HNO<sub>3</sub>, NaOH - H<sub>2</sub>SO<sub>4</sub>. In every case the max. vol. change occurred at the point of neutral-salt formation; the formation of intermediate salts could also be detected. NH<sub>3</sub> solns. showed a contraction, the amt. of which was approx. proportional to the concn. At high concns. the HOAc system showed a small contraction at the beginning of neutralization but later showed an expansion. The other systems showed an expansion. J. B. AUSTIN

**The temporary change of surface tension in solutions of some univalent chlorides.** ERNST O. SEITZ. *Ann. Physik* [5], 1, 1099-108(1929).—A temporary change in surface tension is observed in salt solns. in which complex mols. or ions are formed by polymerization or solvation. On a fresh surface these complex mols. are present in the same concn. as in the interior of the soln., but, having a greater mol. energy than the simple mols., when they travel into the body of the liquid the surface tension is lowered. In the present work surface tensions were measured by capillary rise in various solns. of HCl, NaCl, KCl and LiCl at 5°, 10°, 15°, 20°, 28° and 35°. Fresh surfaces were obtained by an air stream. The non-volatile salts exhibited a linear increase in the final static value of the surface tension with increasing concn. at const. temp., while HCl showed a linear decrease. In all cases the initial surface tension was greater than the final. The period during which the surface tension changes ( $\tau$ ) decreases with rise in temp. The ratio of  $\tau$  for pure water to  $\tau$  for the salt solns. agrees with the Kohlrausch degree of dissocn. at the various temps. The temp. coeff. of  $\tau$  is compared with the temp. coeffs. of inner friction and ionic mobilities. R. H. FERGUSON

**The kinetics of the hydrogenation of ethylene on a copper catalyst of measured surface area.** F. HURN CONSTABLE. *Z. Elektrochem.* 35, 105-10(1929).—The proportions of adsorbed H<sub>2</sub> and C<sub>2</sub>H<sub>4</sub>, the activity of the catalyst and the area of its surface changed with repeated oxidation and reduction. The compn. of the gas mixt. showing max reaction rate changed as the reaction temp. increased, approaching stoichiometric proportions at the higher temps. The total surface was sufficient to accommodate almost a unimol. layer of adsorbed H<sub>2</sub> at 0°, and considerably more than a unimol. layer of C<sub>2</sub>H<sub>4</sub>. It was concluded that at 0° part of the surface was completely free from adsorbed H<sub>2</sub> and that the C<sub>2</sub>H<sub>4</sub> covered a larger part of the available surface. R. L. DODGE

**Kinetics of the oxidation of iodide ion by acid dichromate solutions in presence of a neutral salt.** RALPH F. BEARD AND NELSON W. TAYLOR. *J. Am. Chem. Soc.* 51, 1973-85(1929).—The velocity of the reaction,  $Cr_2O_7^{--} + 6I^- + 14H^+ \longrightarrow 2Cr^{+++} + 7H_2O + 3I_2$ , was measured at 25° with various concns. and in presence and absence of NaCl. For 1.5 M NaCl soln., the results confirm Brønsted's theory that reactions which ordinarily give anomalous reaction nos. may give integrals in the presence of a neutral salt. Two simultaneous reactions are proposed:  $H^+ + I^- + Cr_2O_7^{--} \longrightarrow HI \cdot Cr_2O_7^{--}$ ; and  $2H^+ + 2I^- + Cr_2O_7^{--} \longrightarrow (HI)_2 \cdot Cr_2O_7^{--}$ . The observed velocity const. is  $14.6 [H^+][I^-] + 53,000 [H^+]^2[I^-]^2$ . J. H. REEDY

**Rate of recombination of atomic hydrogen.** HUGH M. SMALLWOOD. *J. Am. Chem. Soc.* 51, 1985-99(1929).—At. H from a Wood tube was passed through a straight tube, and the degree of dissocn. at various points was detd. by measuring the heat effect on Pt foil. The rate of recombination was detd. for a range of 0.5-0.9 mm. of Hg, and was found to conform to the three-body mechanism for exothermic binary reactions. One-sixth to one-fifth of the at. H, under the conditions of the expt. reacted with S, while NO catalyzed the recombination of the at. H. J. H. REEDY

**The ketonic decomposition of  $\beta$ -ketocarboxylic acids.** KAI J. PEDERSEN. *J. Am. Chem. Soc.* 51, 2098-107(1929).—From expts. on the decompn. of  $\alpha$ ,  $\alpha$ -dimethylace-

toacetic acid (I) in HCl solns., the velocity const. for the decompn. in water of the undissocd. acid is found to be 0.000723 at 18°. Measurement of the velocity in glycolate and acetate buffer gives a velocity const. of 0.000004 for the decompn. of the dimethyl-acetoacetate ion. The dissocn. const. at 18° for I is 0.000314. NaCl and undissocd. glycolic acid catalyze the decompn. slightly, while aniline has a great accelerating effect. Undissocd. I decomposes 4.5 times as fast as undissocd. acetoacetic acid. The keto form of  $\beta$ -keto acids is unstable.

ARTHUR FLEISCHER

**Action of hydrochloric acid on alcohol. Effect of electrolytes on the reaction velocity.** S. KILPI. *Z. physik. Chem., Abt. A*, **141**, 424-50 (1929).—The equil. coeff. of the previously developed velocity equations for the action of HCl on EtOH were detd. in aq. mixts. contg. 25 and 50 mol. % of EtOH, and calcd. to temps. of 96.5° and 110°. Measurements were made also in solns. to which had been added KCl and NaCl. The value of the equil. coeff.  $c_2/c_1$  increased with the concn. of the electrolyte (0.05-0.8 *M*), more slowly as the concn. became higher. Since  $c_2$  was shown to be independent of the concn. of the electrolyte, at the concns. used, the value of the velocity coeff.  $c_1$  for the action of HCl on EtOH must decrease as the concn. rises. With the concns. employed, no difference was observed in the action of HCl alone and HCl with NaCl or KCl. An attempt was made to explain the relation between reaction velocity and concn. of electrolyte with the aid of the theories of Brønsted and of Debye and Hückel. In the D and H formula  $A'\sqrt{C}/(1 + \alpha'\sqrt{C})$ ,  $A'$  and  $\alpha'$  were calcd. from the measurements and the value of the coeff. found to agree with the theoretical value. It appears that the velocity of reaction of HCl on EtOH varies with the concn. of electrolyte proportionally to the product of the electrometrically measured activities of H ion and Cl ion. I. J. P.

**Calculation of the water-gas equilibrium by means of the exact Nernst heat equation.** ED MAURER AND W. BISCHOF. *Z. anorg. allgem. Chem.* **178**, 371-80 (1929).—From vant Hoff's isochore by the method of least squares the water-gas equil. was calcd. The values, at 200° intervals from 327° to 1717°, are given and compared with the values given by Luggin, by Hahn, by Haber and Richards, by Engels, by Reinders and by Neuman and Kohler. Log  $K$ , as calcd., is greater than the reported values below 1000° and lies near the value reported by Engels at higher temps. F. E. BROWN

**The velocity of saponification of methyl acetate by sodium hydroxide at 25°.** W. T. GOOCH AND ETHEL M. TERRY. *J. Am. Chem. Soc.* **51**, 1959-65 (1929); cf. *C. A.* **21**, 3526; **22**, 2307, 2703.—MeOAc from three different sources in concns. of 0.008 and 0.016 *M* was hydrolyzed by 0.01 and 0.02 *M* NaOH, resp., at temps. near 25°.  $K$  was calcd. by the equation,  $K = [2.303/(t_2 - t_1)(B - E)] [\log (B - X_1)(E - X_2) / (B - X_2)(E - X_1)]$  where  $E$  = initial concn. of ester,  $B$  of base,  $X$  = concn. of either used up at time  $t$ .  $K_{25,000}$  was found to be  $11.67 \pm 1\%$ , in good agreement with Walker's value 11.7 by the cond. method (*Proc. Roy. Soc. (London)* **A78**, 158 (1906)).  $dK/dT$  was found to be 0.0087 per 0.01°. No difference for  $K$  was found in diffuse daylight and in abs. darkness. An app. is described for shaking a soln. during titration; also one for the rapid measurement of solns. without exposure to air.

F. H. RATHMANN

**Catalysis and atomic physics.** LUDWIG KAUL. *Metallbörse* **18**, 734-5, 846 (1928).—K. attempts to bring observations of Moureu on autoxidation to the support of his own unconventional theories of catalysis.

T. H. CHILTON

**Remarks on the theory of catalysis.** A. BERTHOUD. *J. chim. phys.* **26**, 120-4 (1929).—Dubrisay (*C. A.* **23**, 2093) revives Arrhenius' doctrine of active and inactive mols. Even if such a condition did exist, the introduction of a small amt. of a foreign substance into the system could not effect a change in their concns. J. H. REEDY

**Contact catalysis on metals.** GEORGE B. KISTIAKOWSKY. *Metallwirtschaft* **7**, 676-9 (1928).—General review of catalysis and its industrial application with particular attention to the prevailing theories of the mechanism of the action of metallic catalysts, the effect of promoters and poisons.

R. L. DODGE

**The retarding action of catalysts on the decomposition of hydrogen peroxide.** S. A. DUNAIEV. *Farm. Zhur.* **1928**, No. 3 23-4.—From the 8 catalysts tested, luminal, quinine sulfate, veronal, phenacetin, acetanilide, aspirin, benzoic and salicylic acids, the first two (in additions of 0.02:100.0) gave the best results in tests extending over a period of six months.

E. BIELOUSS

**Action of benzyl bromide and chloropicrin vapors on smooth metallic surfaces.** E. V. ALEKSEEVSKI AND N. S. ALEKSEEV. *Zhur. Prikladnoi Khim.* **1**, 194-200 (1928).—At room temp.  $\text{PhCH}_2\text{Br}$  is less destructive than  $\text{CCl}_3\text{NO}_2$ .  $\text{PhCH}_2\text{Br}$  is more active in dry atm., while  $\text{CCl}_3\text{NO}_2$  is more active in humid atm.  $\text{CCl}_3\text{NO}_2$  in dry atm. and  $\text{PhCH}_2\text{Br}$  in either dry or humid atm. do not destroy metals completely as metals gradually acquire passivity. In presence of moisture  $\text{CCl}_3\text{NO}_2$  completely destroys metals. Vola-

tile compds. are sometimes formed (action of  $\text{CCl}_3\text{NO}_2$  on Zn and Sn in dry atm.). Curves of the reaction rates show that the process is of a very complicated nature.

V. KALICHEVSKY

The catalysis of the reaction between persulfate and iodide ion. II. Remarks on Saal's article "The velocity of ionic reactions. III." A. v. KISS. *Rec. trav. chim.* 48, 508-16(1929); cf. C. A. 21, 2593; 22, 4322.—New data are presented which support the author's earlier interpretation of the mechanism of the reaction between persulfate and iodide ions when catalyzed by ferric ions. An error in Saal's calcs. is indicated. The velocity of the ferric ion-iodide-ion reaction was measured in dil. soln. T. H. C.

A more general statement of the phase rule. PAUL KUBELKA. *Z. Elektrochem.* 35, 335-7(1929).—New terms are introduced into the statement of the phase rule to take care of the independent concns. and energy potentials which may be present in a complicated system. The applicability to a galvanic element is shown in which all other terms are known and the new terms thereby detd. HELEN GILLETTE WEIR

Equilibrium between metals and salts in fusion mixtures. XII. Displacement of the equilibrium in fusions of  $\text{Cd} + \text{PbCl}_2 \rightleftharpoons \text{Pb} + \text{CdCl}_2$  by the addition of a metal phase. RICHARD LORENZ AND MARGARETE HERING. *Z. anorg. allgem. Chem.* 177, 1-12(1929); cf. C. A. 22, 3337.—The effect of adding an indifferent metal phase to the equil.  $\text{Cd} + \text{PbCl}_2 \rightleftharpoons \text{Pb} + \text{CdCl}_2$  is found to be two-fold: (1) One of the original metal phases is ennobled as compared to the other. (2) The equil. isotherms approach the ideal mass-action law and tend to take on the form of a symmetrical hyperbola. Nine ratios of Cd to  $\text{PbCl}_2$  were used and five different amts. of Sb were added. With increase in the amt. of Sb added, the reaction is displaced toward the left, Cd becoming more noble as compared to Pb. Antimony forms compds. with Cd, but this is not the explanation, because Bi forms no compds. with either Cd or Pb and yet it displaces the equil. in the same direction as Sb. ANELLA WIEBEN

Equilibrium between metals and salts in fusion. XIII. The displacement of the equilibrium in fusions of  $\text{Cd} + \text{PbCl}_2 \rightleftharpoons \text{Pb} + \text{CdCl}_2$  by the addition of a salt phase. RICHARD LORENZ AND MARGARETE HERING. *Z. anorg. allgem. Chem.* 178, 33-9(1929); cf. preceding abstract.—The ratios of  $\text{PbCl}_2$  to Cd were 3:1, 2:1, 3:2, 5:4, 1:1, 4:5, 2:3, 1:2 and 1:3. A mixt. of KCl and NaCl in equimolar proportions was added. The molar ratios of total salt (KCl + NaCl) to  $\text{PbCl}_2$  were  $1/2$ , 1, 2, 3 and 4. Nine tables of data and two graphs show that the addition of the salt mixt. always ennobles the Pb as compared to Cd. XIV. Displacement of the equilibrium in fusions of  $\text{Cd} + \text{PbCl}_2 \rightleftharpoons \text{Pb} + \text{CdCl}_2$  by the addition to both phases simultaneously. *Ibid.* 40-8.—The addn. of mixts. of KCl and NaCl shifts the equil. from left to right. The addn. of Sb shifts the equil. from right to left. When equimolar parts of the salts and of Sb are added simultaneously the equil. is shifted from left to right throughout the range of ratios between Pb and Cd except when Pb is very large. F. E. BROWN

Equilibrium between metals and salts in fusion mixtures. XV. The displacement of the point of equivalence in the equilibrium  $\text{Cd} + \text{PbCl}_2 \rightleftharpoons \text{Pb} + \text{CdCl}_2$ . RICHARD LORENZ AND MARGARETE HERING. *Z. anorg. allgem. Chem.* 178, 337-45(1929); cf. preceding abstract.—By point of equivalence is meant that point in the equil. isotherm which results when equiv. amts. of the substances are added, as 1 atom Cd and 1 mol.  $\text{PbCl}_2$ . Addn. to the metal phase displaces equil. to the left; addition of salt (NaCl + KCl) to the salt phase displaces equil. to the right. When equiv. addn. is made to both phases simultaneously, addn. to the salt phase brings about a stronger displacement than the addn. of Sb to the metal phase and still stronger than the addn. of Bi to the metal phase. ANELLA WIEBEN

Determination of transition point by the dilatometric method. MOTOTARO MATSUI, SUTSUO OGURI, HEISCHICHI ISHIKAWA AND SHIRO ISHIDA. *J. Soc. Chem. Ind. (Japan)* 32, 48-54(1929); Suppl. binding 32, 19-23B.—Mathematical development of the theory of the method. S. KONDO

The two crystalline forms of beryllium hydroxide and the system  $\text{BeO}-\text{Na}_2\text{O}-\text{H}_2\text{O}$ . R. FRICKE AND H. HUMME. *Z. anorg. allgem. Chem.* 178, 400-10(1929).— $\text{Be}(\text{OH})_2$  crystallizes in two forms, both having the compn.  $\text{BeO} \cdot \text{H}_2\text{O}$ , but differing in cryst. structure. By aging  $\text{Be}(\text{OH})_2$  gel in cold dil. soln. the metastable form is obtained. This on prolonged shaking with various concns. of NaOH at  $30^\circ$ , or on hydrolyzing  $\text{Na}_2\text{BeO}_2$  or recrystg. from hot, concd. alkali, gives the stable form. The stable form is less sol. in NaOH than the metastable. The soly. of crystd.  $\text{Be}(\text{OH})_2$  in NaOH is independent of the relative amts. of the undissolved phase. At  $30^\circ$ , BeO and NaOH are practically in the ratio 1:1 at equil. When the concn. of NaOH is high, the undissolved phase consists of fine needles easily sol. in  $\text{H}_2\text{O}$  and having the compn.  $\text{BeO} \cdot \text{NaOH} \cdot \text{H}_2\text{O}$ . When

the concn. of NaOH is lower, the undissolved phase consists of stable cryst.  $\text{Be}(\text{OH})_2$ .

ANELLA WIEBEN

**Equilibrium studies concerning the system calcium-sulfur-oxygen.** I. RUDOLF SCHENCK AND KARL JORDAN. *Z. anorg. allgem. Chem.* **178**, 389-99(1929).—Birnbaum and Wittich (*Ber.* **13**, 651(1880)) found indications that at  $500^\circ$ ,  $4\text{CaO} + 4\text{SO}_2 \rightleftharpoons 3\text{CaSO}_4 + \text{CaS}$  (1). It is now found that at  $600^\circ$ , CaO and  $\text{SO}_2$  do not unite mol for mol. Since a deposit of S was observed,  $4\text{CaO} + 6\text{SO}_2 \rightleftharpoons 4\text{CaSO}_4 + \text{S}_2$ . Sestini (*Ber.* **7**, 1295(1874)) reported  $\text{CaSO}_4 + \text{S}_2 \rightleftharpoons \text{CaS} + 2\text{SO}_2$  (2). It is concluded, therefore, that the reaction of CaO and  $\text{SO}_2$  takes place in the two steps (1) and (2). An attempt was made to det. the equil. pressure at the univariant point and to explain and evaluate the equations on the basis of the phase rule and the mass-action equation. It is suggested that the presence in nature of S deposits together with gypsum in the neighborhood of  $\text{CaCO}_3$  may be explained by  $4\text{CaCO}_3 + 6\text{SO}_2 \rightleftharpoons 4\text{CaSO}_4 + \text{S}_2 + 4\text{CO}_2$ .

ANELLA WIEBEN

**The system ferric nitrate-nitric acid-water at  $25^\circ$ .** G. MALQUORI. *Atti accad. Lincei* [6], **9**, 324-5(1929); cf. *C. A.* **22**, 191.—In prepn. for a study of the system  $\text{Fe}(\text{NO}_3)_3 \cdot \text{KNO}_3 \cdot \text{H}_2\text{O}$ , M. studied the above equil. Equil. curves are shown.  $\text{Fe}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$  is prepd. by the action of  $\text{N}_2\text{O}_5$  on the satd. soln. of the  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  in  $\text{HNO}_3$  (d. 1.52). The solid phase was analyzed after pressing out all the liquid between porous plates.

A. W. CONTEMI

**The system:  $\text{MgSO}_4\text{-Na}_2\text{SO}_4\text{-H}_2\text{O}$ .** W. FROELICH. *Z. angew. Chem.* **42**, 660-2(1929).—A critical discussion of both older and more recent data on the system  $\text{MgSO}_4\text{-Na}_2\text{SO}_4\text{-H}_2\text{O}$ , with tables, phase diagram and bibliography. W. C. EBAUGH

**The heat of decomposition of hydrazoic acid.** W. A. ROTH AND FR. MUEHLER. *Ber.* **62B**, 1188-94(1929).—The heat of decompn. of pure liquid hydrazoic acid was obtained by subtracting the heat equivalents of the groups  $\text{C}_6\text{H}_5$  and  $\text{CH}_3\text{COOC}_2\text{H}_5$  from the heats of combustion of phenyl azide and Et azidoacetate. It was found to be 67 cal.  $\pm$  5%. The value calcd. from the data of Berthelot for a dil. soln. was 53 cal. The heat of formation of phenyl azide was more negative by about 70 cal. than that of benzene, while that of Et azidoacetate was smaller by 77 cal. than that of ethyl acetate. The fact that abnormally large amts. of  $\text{HNO}_3$  were formed during combustion of azido and diazo compds. is discussed from an energetic point of view.

FRANK URBAN

**Entropy and its chemical uses.** J. A. V. BUTLER. *Chemistry and Industry* **48**, 598-600(1929).—A short elementary discussion of the entropy and free energy changes in chem. reactions, with applications to a few org. reactions for which these changes may be calcd.

J. B. AUSTIN

**The specific heat of pure iron at high temperatures.** SABURO UMINO. *Science Repts. Tôhoku Imp. Univ.*, 1st Ser., **18**, 91-107(1929).—The mean sp. heat and true sp. heat were obtained for electrolytic Fe by measuring its heat content at various temps. from  $680^\circ$  to  $1560^\circ$  by the method of mixt. The true sp. heat has a const. value between the  $A_2$  and  $A_4$  points, and between the  $A_4$  point and the m. p.; but it increases between the  $A_3$  and  $A_4$  points. The mean sp. heat shows an abnormal increase at the 3 change points, and linearly increases between the adjacent 2 of them with rise of temp. D. S.

**Calculating the specific heats of hydrocarbon vapors.** W. K. LEWIS AND W. H. MCADAMS. *Chem. Met. Eng.* **36**, 336(1929).—Direct exptl. detns. of the sp. heats of  $\text{C}_2\text{H}_6$ ,  $\text{C}_4\text{H}_{10}$  and a mixt. of  $\text{C}_2\text{H}_6$ ,  $\text{C}_3\text{H}_8$  and  $\text{C}_4\text{H}_{10}$  were made by the continuous-flow calorimeter method. The range  $25\text{-}75^\circ$  was covered. Results for the hydrocarbons were about 10% higher than earlier values detd. by indirect methods. For paraffin hydrocarbons at low pressure  $M_c p = 4.4 + 4.4n + (0.012 + 0.006n)t$ , where  $t = \text{temp.}$ ,  $n = \text{number of C atoms per mol.}$ , and  $M_c p = \text{molal heat capacity in g. calories per degree per g.-mol.}$  Rather large deviations from the above equation were found below  $0^\circ$  and at temps. higher than  $75^\circ$ . The equation is directly applicable to mixts. when  $n$  is known.

C. Z. ROSCRANS

**The thermal conductivities of copper and nickel, and some alloys of nickel.** W. C. ELLIS, F. L. MORGAN AND F. G. SAGER. *Rensselaer Polytech. Inst. Bull.*, No. **21**, 23 pp. (1928).—King's method was found to be satisfactory for detg. thermal cond. of metal and alloy wires. The ratio of thermal to elec. cond. for the alloys investigated was somewhat higher than for elementary metals, and not even approx. const. The values were of the same order of magnitude.

E. I. S.

**Determination of the coefficient of heat conductivity.** O. VLASOV. *Izv. Vyssh. Teplotekh. Inst. (Trans. Thermo-Tech. Inst. (Russia))* **1928**, No. **6**, 32-44.—The coeff. of heat cond. of refractory materials, etc., is detd. in a specially constructed app. which has the following features: A water cooler section on the bottom, followed by an insulating layer, an elec. heating element, a thermocouple, a second insulating layer, a thermo-

couple, a heating element, a thermocouple, the material under test and a water cooler on the upper part provided with a thermocouple. The whole is pressed together, the elements are heated by d. c. to insure a uniform temp., which is very essential. The following advantages are claimed. The total amt. of heat measured is equal to the amt. of heat passing through the sample at the given difference in temps., the influence of side losses is actually eliminated. A very complete explanation and calcn. is given, also many details of the temp. measurements. A. A. BOBITLINGK

The thermal equilibrium between ethylene, iodine and ethylene diiodide. R. B. MOONEY and E. B. LUDLAM. *Proc. Roy. Soc. Edinburgh* 49, 160-9(1929).—The pressure of  $C_2H_4$  in equil. with solid  $I_2$  and solid  $C_2H_4I_2$  was measured at temps. between  $10^\circ$  and  $65^\circ$ . The vapor pressure of undissocd.  $C_2H_4I_2$  was measured at 4 temps. between  $15^\circ$  and  $55^\circ$ . From these data the mol. heat of sublimation was found to be 15,700 cal. Equil. const. were calcd. and the heat of formation was calcd. to be 22,300 cal. at  $50^\circ$  for gaseous  $C_2H_4I_2$ . The decompn. of  $C_2H_4I_2$  in  $CCl_4$  was studied at  $100^\circ$ . Expts. were performed on the rates of formation and decompn. of  $C_2H_4I_2$  which showed the reaction to be non-homogeneous. These expts. were carried out in the absence of light. F. W. LAIRD

The crystal structure of tricalcium aluminate (STEELE, DAVY) 6. Freezing temperature of organic compounds. XI. Compounds in  $C_6$  and  $C_8$  (SIMON) 10.

Further progress in crystal analysis. WILLIAM BRAGG. *Chem. News* 139, 55-6 (1929) E. H.

Conversion of energy into matter. G. I. POKROVSKII. *Z. Physik* 55, 771-7 (1929).—Gravitational attraction is thought to be a possible cause of condensation of energy into matter. GEORGE GLOCKLER

Mutual destruction of protons and electrons. C. LÖNNQVIST. *Z. Physik* 55, 789-800(1929).—L. discusses possible methods for the mutual destruction of protons and electrons and hopes to accomplish the feat by bombarding a concd. acid with cathode rays. The resulting radiation would have a wave length of  $\lambda = 0.0000131$  A. U. and a mass absorption coeff. of 0.0001. One mg. of Ra as source should show the effect if every impact is efficient, or a cathode-ray tube could be used. GEORGE GLOCKLER

Terms of hydrogen molecule. G. H. DIEKE. *Z. Physik* 55, 447-50(1929); cf. *C. A.* 23, 3398.—Theoretical interpretation and term designation in the mol. spectrum of H are discussed. Cf. Richardson and Davidson, *C. A.* 23, 3405. G. G.

**Electron distribution in the normal state of helium.** H. BETHE. *Z. Physik* 55, 431-6(1929).—The calcs. of Hylleraas (*C. A.* 23, 3626) of the energy and the eigenfunctions of He in the normal state make it possible to check former methods of calcn. of electron distribution. The method of Hartree (*C. A.* 22, 1269) of the self-consistent field gives excellent checks.

GEORGE GLOCKLER

**Optical behavior of hydrogen atoms in very strong electric fields.** R. VON TRAUBENBERG. *Physik. Z.* 29, 895(1928).—The effect of sudden changes in field strengths up to 420,000 v./cm. on H atoms has been studied by means of Stark's arrangement of sept fields, and the Stark effect measured in the second order for Balmer lines. The proportionality with the square of the field strength is confirmed for all components of  $H_\gamma$ . The results for the middle component agree better with the theory of Schrödinger than with that of Epstein, but considerable deviations from Schrödinger's values are shown for the higher components.

B. C. A.

**Dissociation of pure mercury.** E. S. KEEPING. *Nature* 122, 728(1928).—Bradley's results (*C. A.* 23, 745) are criticized. Values of  $p/q$ , where  $p$  and  $q$  are the av. nos. of free electrons per atom of the metal X and Hg, resp., are recorded for In, Mg, Tl, Ge, Sb, Y, Ce, Ga, Cu, Cd and Ag.

B. C. A.

**Kerr effect and molecular structure.** H. A. STUART. *Z. Physik* 55, 358-70(1929).—The importance of the Kerr effect for questions of mol. structure is discussed. Equations contg. the elec. moment, and optical and elec. anisotropy are compared with equations of mol. refraction. The Kerr constant is sept. into two members relating to the dipole moment and the anisotropy of the mol. The optical polarizabilities of HCl,  $NH_3$  and  $SO_2$  are calcd.

GEORGE GLOCKLER

**Quantum mechanics of molecules.** H. LUDLOFF. *Z. Physik* 55, 304-26(1929).—Wave-mechanical calcs. lead to term values of the  $H_2$  mol. in fair agreement with expts. Cf. R. T. Birge, *C. A.* 22, 1722.

GEORGE GLOCKLER

**Isotope effect in the spectrum of neon.** HANTARO NAGAOKA AND TADAO NISHIMA. *Proc. Imp. Acad.* (Tokyo) 5, 200-2(1929).—A tube of Ne was immersed in liquid air and observed transversely to avoid self-reversal through an unsilvered part of the Dewar vessel. When the air plate was about 4 cm. thick, every strong line in the red and yellow portions of the spectrum was associated with a weak one, nearly in the middle between succeeding fringes. This character is evidently different from ordinary close doublets or hyperfine structure and as the difference in wave length did not show much deviation from the calcd. value for Ne(22) by the change in Rydberg const. it must be attributed to the isotope effect. A table gives the position of the lines relative to the usually accepted lines of Ne.

C. J. WEST

**Radioactive disintegration and relativity theory.** CHR. MØLLER. *Z. Physik* 55, 451-66(1929).—The calcs. of Gamov (*C. A.* 23, 1047), Gurney and Condon (*C. A.* 23, 2647) and Kudar (*C. A.* 23, 2352) of radioactive disintegration as based on wave mechanics are repeated. M. considers the problem mathematically from the point of view of relativity theory.

GEORGE GLOCKLER

**Counting of  $\alpha$ -particles by Wulf's method.** MILE M. DESMET AND MILE M. VAN HAEPEREN. *Ann. soc. sci. Bruxelles* 48B, 1, 100-13(1928).—A comparison of the improved ionization-chamber method of counting  $\alpha$ -particles of Wulf (*Physik. Z.* 26, 382(1925)) with the scintillation method. By using as a const. source of  $\alpha$ -particles a small sphere of polished steel activated by means of Rn, the optical method gave 15 particles/min. Wulf's method gave values of 10-13 in the most favorable cases with dull pointed needles, and only 3-5 with fine-pointed needles. Particular attention was paid to the cleaning of the needles, shape of the point, and sign and magnitude of the voltage applied. Since the scintillation method almost certainly gives a low result, Wulf's method is not considered suitable as an accurate quant. method.

B. C. A.

**Variations in the ionization effect due to single  $\alpha$ -rays.** A. PICCARD AND E. STAHEL. *Helv. Phys. Acta* 1, 437-40(1928)(In German); *Science Abstracts* 32A, 242. P and S investigate a no. of causes which may produce variations in the amt. of ionization. These include chance encounters of two or more  $\alpha$ -rays, deviations of  $\alpha$ -rays through large angles, "absorption" of  $\alpha$ -rays by nuclei with which they collide, variations which take place when the  $\alpha$ -ray and the elec. field are not parallel, changes in the charge of the  $\alpha$ -ray during its course. None of these causes is capable of explaining the variations observed by Greinacher and by Ramelet. Hoffmann obtains quite different results from those of these experimenters.

H. L. D.

**Researches upon the transformation of elements.** L. THOMASSEN. *Metallwirtschaft* 7, 703-8(1928).—A review. The expts. of Smits (*C. A.* 20, 2449) in the transmutation of Pb into Hg and Tl in a quartz-Pb lamp are repeated with negative results.

ROBERT F. MEHL

**Electrons and quanta.** C. J. DAVISSON. *J. Optical Soc. Am.* **18**, 193-201(1929).—Several aspects of the evidence for the inter-relationship of electrons and waves are presented. D. discusses the diffraction of electrons and the wave length of such particles as compared to x-rays and their behavior. The expts. of Nishikawa and Kikuchi are mentioned, as being of potential importance. WILLIAM E. VAUGHAN

**Ionization potentials and atomic number.** R. PETERLS. *Z. Physik* **55**, 738-43 (1929).—The trend of ionization potentials in B, C, N, O, F and Ne as found exptly. is deduced theoretically from wave-mechanical considerations. Cf. Alexander, *C. A.* **23**, 2877. GEORGE GLOCKLER

**Wilson cloud chamber for small pressures.** J. PETROVÁ. *Z. Physik* **55**, 621-7 (1929).—A modified app. is described which permits the study of both  $\alpha$ - and  $\beta$ -ray tracks at pressures of 3 cm. Hg and higher. GEORGE GLOCKLER

**Range of  $\beta$ -rays from radium D by the Wilson cloud-chamber method.** J. PETROVÁ. *Z. Physik* **55**, 628-45(1929).—The app. described in the preceding abstract was used to det. the ranges of  $\beta$ -rays from Ra D at various pressures. The two strongest secondary  $\beta$ -ray groups have av. normal ranges ( $20^\circ$ , 760 mm.) of 0.80 and 1.58 cm., resp. Their max. ranges are 1.3 and 2.4 cm. The existence of a primary  $\beta$ -ray group of Ra D is inferred. GEORGE GLOCKLER

**Theory of diffusion of electrons through gases.** H. BARTELS. *Z. Physik* **55**, 507-32(1929).—The diffusion of electrons through a gas layer is analogous to the scattering of a light beam. A mathematical discussion is given. Cf. G. Hertz, *C. A.* **19**, 2908. GEORGE GLOCKLER

**Electron terms of the singlet system in the molecular spectrum of hydrogen.** W. WEIZEL. *Z. Physik* **55**, 483-501(1929).—All of the known electron terms in the mol. spectrum of H can be interpreted as due to jumps of one electron while the other electron is in the lowest  $1s\sigma$  state. All the terms are calcd. and the ionization potential of H is 15.75 v., in agreement with the value 15.9 v. obtained by electron impact expts. Cf. *C. A.* **23**, 769. GEORGE GLOCKLER

**Ramsauer effect of argon.** J. HOLTSMARK. *Z. Physik* **55**, 437-46(1929); cf. *C. A.* **22**, 3836. The av. field of the A atom is calcd. after Hartree (*C. A.* **22**, 1269) and the polarization produced by the impinging electron is taken into account. On this basis the effective cross-section of A towards impinging electrons is calcd. in agreement with expt. GEORGE GLOCKLER

**Determination of H-rays with the tube electrometer.** E. A. W. SCHMIDT AND G. STETTER. *Z. Physik* **55**, 467-82(1929).—Expts. are described of the counting of H-rays and the detn. of their ionization by means of a tube electrometer. The sp. ionization of H-rays and  $\alpha$ -rays is in the ratio 1:4. This ratio is const. for various velocities and angles. Measurements by the scintillation method give higher values than by the elec. method. Cf. Ortner and Stetter, *C. A.* **23**, 3623. GEORGE GLOCKLER

**Wave mechanics.** C. F. HAGENOW. *Sci. Monthly* **1929**, 109-16.—A review. E. H.

**Absorption of Hertzian waves in ionized gases.** HERMANN DÄNZER. *Ann. Physik* [5], **2**, 27-62(1929).—D. has designed a Hertzian wave detector capable of receiving any desired wave length, operating on the bolometer principle. The construction of the sender and the receiver is carefully described. The absorption of A, H, N, O and air in a discharge tube with Mg electrodes was investigated and also the "life-period" of free electrons,  $T$ , in these gases. (By life-period is meant the time between excitation and total cutting-off of the absorption.) Pure A absorbs 97% (max.); mixt. of A and H<sub>2</sub>, about 97%; slightly impure A, 84%; very impure A, 90%; H<sub>2</sub>, 100%; N<sub>2</sub>, 78%; air, 94%; O<sub>2</sub>, 87%.  $T$ : A,  $2 \times 10^{-3}$  to  $1 \times 10^{-1}$ ; H<sub>2</sub>, about  $3 \times 10^{-4}$ ; N<sub>2</sub>,  $3 \times 10^{-4}$ ; O<sub>2</sub>,  $1 \times 10^{-4}$ ; air,  $1 \times 10^{-4}$ . A long theoretical discussion is given wherein are derived the equations  $1 - n^2 = (1/\pi c^2) \cdot (Ne^2/m)\lambda^2$  and  $\mu = (ze\lambda^2/2\pi c^3) \cdot (Ne^2/m)$ , in which  $n$  is the refractive index,  $\mu$  the absorption coeff.,  $e$  and  $m$  are the ion charge and mass,  $Z$  is the no. of impacts per ion per sec. and  $\lambda$  the wave length.  $N$  is the detg. factor for the absorption. WILLIAM E. VAUGHAN

**Ionization in stellar atmospheres. I. Generalized Saha formulas, maximum intensities, and the determination of the coefficient of opacity.** E. A. MILNE. *Month. Not. Roy. Astron. Soc.* **89**, 17-49(1928).—Mathematical. II. **Absolute magnitude effects.** *Ibid.* 157-75.—Formulas are obtained which det. the variation with  $g$ , at const.  $T$ , of the no. of atoms responsible for the formation of a given absorption line. The behavior depends on whether the coeff. of general absorption,  $\kappa$ , is const. throughout the stellar atm. or is proportional at each point to the electron pressure  $P$ . The fact that lines of both neutral and ionized atoms increase in intensity from dwarfs to giants favors the adoption of  $\kappa \propto P$ . When  $\kappa \propto P$  the mass of the reversing layer increases with decreas-

ing pressure and more than counterbalances the reduction in the proportion of neutral atoms due to increased ionization. The observed strengthening of the Balmer lines from dwarfs to giants now receives theoretical explanation. B. C. A.

**Theoretical contours of absorption lines in stellar atmospheres.** E. A. MILNE. *Month. Not. Roy Astron. Soc.* 89, 3-17(1928).—Math. The no. of atoms per cc. in a stellar atm. is calcd. on the assumption of no surface of demarcation between atm. and photosphere. B. C. A.

**Nature of streamers in electric sparks.** MICHIO MIYANISHI. *Japan. J. Physics* 5, 67-82(1928).—The streamers emanating from the anode and cathode of a spark have been examd. spectrographically and found to consist of positively and negatively charged particles, resp. Their velocity and duration of luminosity have also been measured. B. C. A.

**Critical potentials of methane.** F. PIETSCH AND G. M. SCHWAB. *Z. Physik* 55, 231-3(1929).—The interpretation of the processes taking place at the ionization potentials of  $\text{CH}_4$  by Hogness and Kvalnes (*C. A.* 23, 2650) is discussed. At 15.4 v.  $\text{CH}_4$  decomposes into C and  $2\text{H}_2$  and  $\text{CH}_3^+$  ions are formed. GEORGE GLOCKLER

**A proposed method for determining whether or not an electron has a magnetic moment comparable with that of a hydrogen atom.** V. M. ALBERS AND T. E. PIPPS. *Phys. Rev.* 31, 149(1928).—In order to decide whether or not the magnetic moment of the H atom is due to the electron in the atom, an expt. is proposed similar to Brillouin's except that the electrons will be generated within the magnetic field and will then travel parallel to it. H. R. MOORE

**Ionization of water vapor.** H. A. BARTON AND J. H. BARTLETT. *Phys. Rev.* 31, 154-5(1928).—The method of electromagnetic analysis was used to study the nature of ions formed by electron impact in  $\text{H}_2\text{O}$  vapor.  $(\text{H}_2\text{O})^+$  and  $(\text{OH})^+$  were predominant. The ionization potential of the former was  $13 \pm 1.5$  v. H. R. MOORE

**Time lag differences of the Faraday effect in several mixtures and chemical compounds.** FRED ALLISON. *Phys. Rev.* 31, 313(1928); cf. *C. A.* 22, 1507.—The Faraday effect lags behind the magnetic field longer in one liquid than another. The effect has now been studied systematically with several org. liquids. Since mixts. of 2 or more liquids gave lags characteristic of their components, the method may have possible application in detecting the presence of certain constituents present. H. R. MOORE

**Concentration and dilatation effect produced by a longitudinal magnetic field on a beam of slow electrons.** J. THIBAUD. *Compt. rend.* 188, 158-60(1929), cf. *C. A.* 23, 3156. B. C. A.

**Influence of a magnetic field on the fluorescence of mercury vapor.** H. NIEMOŁ NICZAŃSKI. *Z. Physik* 55, 676-89(1929).—The strengthening of the resonance radiation reported by Franck and Grotrian (*C. A.* 15, 3585) is not found. Other effects are noted. GEORGE GLOCKLER

**Selective photoelectric effect.** R. SUHRMANN AND H. THEISSING. *Z. Physik* 55, 701-16(1929); cf. *C. A.* 22, 2512, 3831.—Monatomic and thicker layers of K films were studied. GEORGE GLOCKLER

**Note on the effect of temperature on the auto-electronic discharge.** N. A. DE BRUYNE. *Proc. Cambridge Phil. Soc.* 24, 518-20(1928).—In the presence of both thermionic and auto-electronic emission sepn. may be made by subtracting thermionic current, obtained by the Schottky relation, from total measured current; the diff. equals auto-emission at the temp. considered. The auto-emission is found to be independent of temp. up to  $1944^\circ$  (highest temp. investigated) contrary to the expts. of Millikan and Eyring and Millikan and Lauritsen (*C. A.* 22, 1272). Auto-emission appears to be independent of thermionic emission. M. McMAHON

**The effect of gases on the electric charges developed by heated metals.** DONALD H. BANGHAM AND DOUGLAS R. LEWIS. *J. Chem. Soc.* 1929, 1140-9.—Hartley's expts. (*C. A.* 8, 2102) on detg. charges of metal surfaces heated in contact with various gases were repeated with particular emphasis on the magnitude of the currents obtained. The metal surface investigated was a roll of Au gauze. With O at temps. of  $468^\circ$  and  $497^\circ$  there was a positive displacement of "equil. potential," a function of its pressure. The observed effects are due to an exchange of ions between metal surface and glass wall. M. McMAHON

O. With H there was a negative displacement of "equilibrium potential" with increase of pressure. Occluded O and N diminish the emission of ions from metal; H increases emission at low pressures. M. McMAHON

The resolving power of an octahedral crystal for x-rays. CARLETON C. MURDOCK

*Phys. Rev.* **31**, 304(1928).—A study of the relation between the size of octahedral crystals of the cubic system and the width of the lines of their x-ray powder spectrogram has led to an equation very similar in form to that of Scherrer. Computations of particle vol. for colloidal particles such as Au and Pt, which ordinarily crystallize in the octahedral form give results 20% less than those based on the assumption that the particles are cubes. H. R. MOORE

An attempt to find a unidirectional effect of x-ray photons. A. H. COMPTON, K. N. MATHUR AND H. R. SARNA. *Phys. Rev.* **31**, 159(1928).—Expts. were carried out to test the idea that x-ray pulses excited by the impact of cathode particles on a target might emit more photons with their elec. axes antiparallel to the cathode stream than parallel to it. It was thus anticipated that more photoelectrons would be ejected parallel to the cathode rays. The expts., however, were neg., or at least below the limits of detection, 1 part in 500. H. R. MOORE

The soft x-ray emission from various elements after oxidation. L. P. DAVIES. *Proc. Roy. Soc. (London)* **A124**, 268-77(1929); cf. *Proc. Roy. Soc.* **A119**, 543(1928).—The effect of oxidation on the total soft x-ray emission from Si, Mn, Co, Ni, Cu, Mo, Pd and W was studied. The efficiencies are leveled up after oxidation, which suggests that the efficiency of the oxide is the av. efficiency of the O and element present. The mean value for the efficiency of O calcd. on this basis is  $3.61 \times 10^{-6}$  at 600 v.,  $3.15 \times 10^{-6}$  at 500 v.,  $2.82 \times 10^{-6}$  at 400 v. and  $2.06 \times 10^{-6}$  at 300 v. H. W. WALKER

X-radiation from the impacts of electrons against gas atoms. WILLIAM DUANE. *Phys. Rev.* **31**, 708(1928); cf. *C. A.* **22**, 4057.—X-rays produced by impact of electrons on Hg atoms have been shown previously to possess an av. wave length somewhat longer than the short-wave length limit given by the quantum equation. A further extension is described on measurements of radiation at right angles to the electron stream, in which thinner windows were used, and also expts. on radiation emitted in the direction of motion of the electrons. H. R. MOORE

Absolute measurements of intensity of Röntgen rays. O. GAERTNER. *Ann. Physik* [5], **2**, 94-122(1929).—The intensity of filtered radiations from a hot cathode tube with Cu or Mo anode is measured with a thermopile (calibrated electrically). The detd. intensities are compared with the ionization produced by the radiation in H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, A and air. The ratio volt per ion-pair is detd. for N<sub>2</sub>, 40.8; air, 36.4; O<sub>2</sub>, 34.4; A, 29.6 (all for av. wave length 1.38 A. U.). WILLIAM E. VAUGHAN

Indices of refraction of platinum for x-rays of long wave length. ELMER DERSHEM. *Phys. Rev.* **31**, 305(1928).—By a reflection method the refractive indices of Pt measured over the wave length range 1.279-701 A. U. yield values of  $1-\mu$  of  $27.3 \times 10^{-6}$  to  $663 \times 10^{-6}$ . H. R. MOORE

Diffraction of x-rays by ruled gratings. Spectrographic function of x-rays and ultra-violet rays. J. THIBAUD. *Ann. soc. sci. Bruxelles* **48B**, ii, 145-68(1928); cf. *C. A.* **22**, 2713.—An account of the author's work on the diffraction of x-rays and ultra-violet rays showing the various stages in the development of the grating method with tangential incidence. This method is compared with the rotating-crystal method, and is shown to be very suitable for the investigation of the region between x-rays and ultra-violet rays. The theory of the diffraction grating with tangential incidence is summarized and a detailed description of the improved form of vacuum spectrograph with glass grating is given (cf. *C. A.* **21**, 1593). B. C. A.

Use of optical gratings for x-rays of one to two A. U. H. SEEMANN AND K. F. SCHOTZKY. *Z. Physik* **55**, 252-72(1929).—Glass gratings of 142 lines per mm. give x-ray spectra with Cr rays of 2.3 A. U. Gratings with more lines cannot be used. G. G.

X-ray spectra of gases. A. BJORKESON. *Z. Physik* **55**, 327-37(1929); cf. *C. A.* **22**, 4057.—Several methods are described for photographing x-ray spectra of gases. Na, K and S are used. The common principle of the methods is the use of a beam of electrons which crosses a beam of the vapor. GEORGE GLOCKLER

The third orbit of the ionized atoms P II, S II, S III and Cl III. Quadruplets of Cl III. J. GILLES. *Compt. rend.* **188**, 1158-60(1929); cf. *C. A.* **23**, 1570, 2103.—Previous work of Ingram on S II and of the author on S III is referred to, which indicate that in these ions the 3rd orbit is very close to 4s. In P II, however, which is isoelectronic with S III, the 3rd orbit is at a normal distance from 4s. Quadruplets of Cl III due to the following combinations are given:  $a3d^4P - a4p^4S$ ,  $a3d^4P - a4p^4P$ , and  $a3d^4P - a4p^4D$ . The values of the terms are computed from Bowen's published terms. It appears that in Cl III the 3d orbit comes between 4s and 4p. C. J. HUMPHREYS

Electromagnetic equations in the quantum theory. C. G. DARWIN. *Nature* **123**, 203(1929).—Mathematical. H. L. D.

Elementary processes in emission and absorption of light. J. STARK. *Ann.*

*Physik* [4], **87**, 909-26(1928); cf. *C. A.* **23**, 2652.—An earlier theory given by Stark is extended and applied to a series of exptl. cases. In the emission of light, first the electron in its stationary state in the atom is displaced from equil. and approaches indefinitely close to a lower energy level. Second, a light quant. is formed in the electronic field. Third, there is a mutual action between the electron and the light quant. resulting in the emission of the quant. in a definite direction with the velocity of light, and fixing of the electron in the new energy level. The time required for each of these processes is discussed. Consideration is given to excitation by cathode rays, and the theory predicts that the emission of characteristic frequencies in consequence of transfers of the at electron from one energy level to another is accompanied by the emission of a continuous spectrum in the infra-red or the beginning of the visible spectrum; also, that if the energy of the impinging electron is less than that required to raise the at. electron to the next higher level an aggregate of atoms will give rise to a continuous spectrum. The theory provides an explanation of the continuous x-ray spectrum. The theory is applied to all kinds of absorption, including continuous, selective and photoelectric absorption, and absorption due to scattering. B. C. A.

**Photometric and spectrophotometric investigations. VI. Reflection spectroscopy.** K. SCHAU. *Z. wiss. Phot.* **26**, 97-110(1928)—Measurements were made with the Köning-Martens spectrophotometer. Data are given for the following materials; pigments; samples of silk, cotton and paper colored with some azo dyes; and a few colored mirrors. The method of investigation is described at length. A. P. H. TRIVELLI

**Effect of the addition of hydrogen and water on the radiation emitted from the carbon monoxide flame.** WM. E. GARNER AND F. ROFFEY. *J. Chem. Soc.* **1929**, 1123-40.—The addn. of H<sub>2</sub> or water decreases the radiation from the flame and increases the speed of flame. The difference between the effects of the two gases is slight. There is a crit. region at 0.02-0.04% of H<sub>2</sub>, where the radiation falls abruptly, and the properties of the flame undergo a marked change. Radiation-compn. and radiation-speed curves give a break at this point. Logarithmic relationships are found to hold between the speed of flame and the radiation emitted. These apply to mixts. above and below the crit. point. They support the "energothermic" theory of catalysis. The step on the radiation curves is considered to be due to a change in the nature of the chem. reaction L. L. QUILL

**Ultra-violet bands of sulfur.** J. GILLES. *Compt. rend.* **188**, 1607-8(1929) - Tables are given of ultra-violet bands from sulfur. GREGG M. EVANS

**Heat spectrum of solid and liquid iron.** R. HASE. *Physik. Z.* **29**, 904-7(1928) — The spectral energy distribution of the radiation emitted by solid and liquid Fe resembles that from a black body, but the abs. intensity depends largely on surface oxidation. The wave length of max. emission for smooth solid Fe is shifted in the direction of shorter wave lengths as the temp. rises, so that Wien's law is obeyed. The intensity *E* at the max. varies as  $CT^6$ , *T* being the abs. temp. and *C* = 2890. Mat. slag-free Fe emits approx. "gray" radiation approaching the black-body condition as the temp. rises. The heat spectrum of liquid Fe closely resembles that of the smooth solid metal both as regards intensity and spectral distribution. B. C. A.

**Hyperfine structure of doublet spectra and the determination of nuclear moments.** H. SCHÜLER AND H. BRÜCK. *Z. Physik* **55**, 575-80(1929).—The appearance of hyperfine structure of spectral lines necessitates the adoption of a new quantum no. representing the magnetic moment of the nucleus. Energy-level diagrams are discussed and for TI the nuclear moment is  $1/2$ . GEORGE GLOCKLER

**Ultra-violet bands of the hydrogen molecule.** A. SCHAAPFMA AND G. H. DIEKE. *Z. Physik* **55**, 164-86(1929).—Most of the lines between  $\lambda$  1250 and 1700 Å. U. are assigned to the *B-A* band system. Cf. Kemble and Guillemin (*C. A.* **23**, 1053) and Richardson and Davidson (*C. A.* **23**, 2883). GEORGE GLOCKLER

**Intensity in the hydrogen Stark effect.** H. MARK AND R. WIERL. *Z. Physik* **55**, 156-63(1929); cf. *C. A.* **23**, 2363. GEORGE GLOCKLER

**Light scattering in quartz and silicates.** E. GROSS AND M. ROMANOVA. *Z. Physik* **55**, 744-52(1929).—The Raman effect is studied in quartz and glass. The glasses show the Raman lines of quartz as diffuse bands. GEORGE GLOCKLER

**Absorption spectra and constitution of azo and azoxy compounds.** I. SZEGÖ. *Ber.* **62B**, 736-44(1929); cf. *C. A.* **23**, 337.—Ultra-violet absorption spectra are given for azo- and azoxybenzene and the nitro, hydroxy, methylamino and bromo derivs. of azobenzene and the  $\alpha$ - and  $\beta$ -azoxybenzene. J. G. McNALLY

**The polarization of light from hydrogen canal rays.** F. G. SLACK. *Phys. Rev.* **31**, 312(1928).—Light emitted at right angles to a stream of H canal rays is partially polarized. Thus the resultant light is partially polarized with its elec. vector parallel to the

beam. The computed ratios of parallel intensity to perpendicular intensity are in agreement with the recent expts. H. R. MOORE

**Measurement of optical rotation in the further ultra-violet.** WERNER KUHN. *Ber.* 62B, 1727-31(1929).—In view of the relationships between rotation anomalies and absorption bands, any work on the relationship between optical rotation and chem. constitution with the simpler compds., which generally lack absorption bands in the visible regions, must be carried out in the ultra-violet, where absorption bands do occur. K. describes a new polarization app. using quartz instead of calcite Rochon or Sénarmont prisms, with spectrograph for eye-piece, giving photographic records for interpretation of readings. A. P. SACHS

**Photometric study of the Raman effect.** PIERRE DAURE. *Compt. rend.* 188, 1605-6(1929).—Measurements on Raman lines from  $\text{AsCl}_3$ ,  $\text{PCl}_3$  and  $\text{CCl}_4$  show that within the limits of exptl. error, the relation  $r$ , between the intensity of the pos. and neg. rays from the same excitation follow the equation  $r = e^{-nhc/kT} = e^{-nhcN/RT}$ , where  $n$  is the difference between the exciting and the Raman radiation frequency, and the other symbols have their usual meaning. The intensity of the Raman emission varies with the fourth power of the exciting frequency. The Raman energy attains in certain cases  $1/10$  that emitted by mol. scattering. GREGG M. EVANS

**Selection rules in the Raman effect.** F. RASETTI. *Nature* 123, 757-9(1929).—In order that a Raman shift corresponding to the transition  $i \rightarrow k$  may be observed, both  $i$  and  $k$  must combine at least with a third state  $l$ ; the Raman scattering becoming particularly intense when the energy  $h\nu$  of the impinging quantum is near to  $E_l - E_i$ . Using the Hg line 2536, R. has photographed Raman lines from O, N and H and finds that the observed values support the above statement. Lines due to rotational transitions are observed on either side of the 2536 line in O. The measurements support the hypothesis that in  $\text{N}_2$  only even rotational states are present. GREGG M. EVANS

**New properties of polarized fluorescence of liquids.** S. I. VAVILOV. *Z. Physik* 55, 690-700(1929).—The polarization of the fluorescence of dye solns. in glycerol is different on transverse than on longitudinal observation. The degree of polarization changes periodically with the wave length of the exciting light. Both effects are thought to be due to light pressure. GEORGE GLOCKLER

**Phosphorometer for the rapid measurements of the intensities of phosphorescences.** R. COUSTAL. *Compt. rend.* 188, 326-7(1929).—The intensity or decrease of phosphorescence of the substance to be examd is matched by means of mixts., in known proportions, of varying amts. of two  $\text{ZnS}$  from the same batch, of which only one has been rendered phosphorescent. The surface ds. of such mixts. are proportional to the concns. of the active sulfide. The intensities of phosphorescence show the same rates of decrease with time and the Güntz formula was confirmed. B. C. A.

**Chemiluminescence.** ERIC K. RIDEAL. *Chem. News* 139, 33-6(1929); *Proc. Roy. Inst. Gl. Britain* (preprint), Feb. 15, 1929, 6 pp.—A review. E. H.

**Diffusion of photoluminescence.** G. A. GAMBURZEV. *Z. Physik* 55, 533-45(1929).—Resonance light can travel through a gas by repeated process of absorption and emission and thereby suffer considerable retardation. The problem is treated mathematically. This retardation is considerable in resonance radiation but it is not very marked in the luminescence of uranyl salts. GEORGE GLOCKLER

**Band fluorescence and heat of dissociation of mercury molecules.** S. MROZOWSKI. *Z. Physik* 55, 338-57(1929).—The intensity relations in bands obtained in fluorescence of Hg vapor are studied as a function of temp. and vapor density. The measurements give 1700 cal./mol. for the heat of disson. of Hg mols. Cf. C. A. 23, 39. G. G.

**Study of fluorescent power of solutions. Influence of concentration. Action of antioxygens.** F. VITTE. *J. chim. phys.* 26, 276-87(1929).—By means of a fluorometer designed by F. Perrin, the change of fluorescent power of fluorescein in 0.1 N NaOH and  $\text{NH}_4$  in glycerol,  $\text{H}_2\text{O}$ , and alc. and of erythrosin in very dil. solns. were measured. The results agree with J. Waruloff. The effect of viscosity of the solvent is slight. Curves for fluorescent power in presence of KI and resorcinol were detd. A. F.

**Thermoluminescence excited by high-voltage cathode rays.** FRANCES G. WICK AND EDNA CARTER. *Phys. Rev.* 31, 713(1928); *J. Optical Soc. Am.* 18, 383-92(1929).—Specimens of powdered calcite, fluorite and  $\text{MgSO}_4$  were irradiated with a powerful stream of electrons from the Coolidge cathode-ray tube. The activation was preserved by immersion in liquid air. Photometric measurements of max. brightness and the decay of thermoluminescence were observed under various conditions. H. R. M.

**A luminescent effect in electrolysis at mercury electrodes.** A. DUMANSKI. *Z. CHEŠHEVA AND A. BANOV. Z. physik. Chem., Abt. B*, 3, 440-2(1929).—In electrolysis of salt solns. where Hg is the positive electrode a luminescence with formation of insol.

compds. is observed. In those salt solns. which do not form insol. compds. there is none. The intensity increases with concn. of solns. up to about 0.1 *N*, but the duration is inversely proportional to the concn. With 0.1 *N*  $\text{AlCl}_3$ , the spectrum extended from 510 to 617  $\mu$ , and with 0.1 *N*  $\text{NaCl}$ , between 510 and 607  $\mu$ . The effect is independent of the material of the neg. electrode.

GREGG M. EVANS

A proposal for the designation of a quantity of light in photochemistry. MAX BODENSTEIN AND CARL WAGNER. *Z. physik. Chem., Abt. B*, 3, 456-8(1929).—In order to make the nomenclature of photochemistry consistent with ordinary chem. symbolism B. and W. propose the following conventions. By analogy with electrochemistry, a unit of  $6.06 \times 10^{23}$  quanta is to be called one "light equiv." or "einstein" and is to be denoted by the letter *E*. The number of einsteins is to be denoted by *L*. The intensity of the absorbed light,  $J_{\text{abs}}$ , is to be expressed in einsteins per sec. The symbol [ $J_{\text{abs}}$ ] is to denote the number of einsteins absorbed per liter per sec.

J. B. AUSTIN

The photochemical formation of phosgene. IV. Changes at low pressures and an improved conception of the mechanism of the reaction. MAX BODENSTEIN, SAM LENCHER AND CARL WAGNER. *Z. physik. Chem., Abt. B*, 3, 459-78(1929).—Exptl. observations on the formation of  $\text{COCl}_2$  at room temp. and pressures below 30 mm. Hg show that the reaction proceeds more slowly than is to be expected from the velocity equations at higher pressures. This leads to the conclusion that the Cl atoms disappear not only through events taking place in the gas space, but also wander to the walls and recombine there. The bearing of this observation on the present conception of the mechanism of phosgene formation is discussed at some length.

J. B. AUSTIN

Photochemical decomposition of benzaldehyde in vapor state. MARC DE HEMPTINNE. *J. phys. radium* 9, 357-64(1928); cf. *C. A.* 22, 2717.—Vapor-phase photochem. decompn. of benzaldehyde is produced by a region of ultra-violet corresponding to complete absorption. With rising temp. longer wave lengths cause the decompn. Thermal decompn. without a catalyst above 400° gives similar products. Decompn. by electromagnetic, thermal or electronic bombardment (silent discharge) energy leads to the same products, and in case of the first two the use of either one decreases the quantity of the other necessary to cause decompn.

A. P. SACHS

The use of a new actinometric material. W. EISENSCHIMMEL. *Listy Cukrova* 47, 451-2(1929); cf. *C. A.* 22, 356.—Artificial light has no effect upon the chloramine, all reactions were studied under sunlight. Red and green light have no effect on the reaction; the greatest reaction rate occurred in the blue. Changes in temp. ( $0-10^\circ$ ) have no effect upon the rate of reaction. Diln. of the soln. increases the rate of reaction.

FRANK MARESH

Photochemical reaction between ethylene glycol and dichromate. J. H. RIENSEN-FELD AND O. HECHT. *Z. wiss. Phot.* 26, 369-72(1929).—The  $\text{H}_2\text{O}$ -free dichromate soln. in glycol is more light-sensitive than that of the  $\text{H}_2\text{O}$ -contg. dichromate. Quant. detns. were made. Within the concn. limits of a 0.2-0.6%  $\text{Na}_2\text{Cr}_2\text{O}_7$  in ethylene glycol, the amt. of photochemically changed material is proportional to the time of exposure. With the light intensity used, independently of concn. and thickness of layer, 50 milli-equivs. of  $\text{Na}_2\text{Cr}_2\text{O}_7$  were reduced (1 milli-equiv. is 1.31 mg. of  $\text{H}_2\text{O}$ -free  $\text{Na}_2\text{Cr}_2\text{O}_7$ ).

A. P. H. TRIVELLI

New light reaction of ergosterol. A. STEIGMANN. *Z. wiss. Phot.* 26, 363-8(1929).—S. describes several qual. light reactions of ergosterol with methylene blue and anthraquinone in pyridine and alc. with an O atm.

COLIN G. FINK

The electric steel furnace in Germany, Austria, Hungary and Czechoslovakia. VEREIN DEUTSCHER GIESSEREIFACHLEUTE. *Die Gießerei* 16, 437-43(1929).—A detailed report based upon 18 responses received to a questionnaire sent to all steel works in the above countries. The report includes 1 acid direct arc and 23 basic indirect arc furnaces, ranging from 1-ton to 15-ton capacity. Voltages range from 60 to 200. Statistics are given on energy consumption and refractory consumption. Many other details, such as furnace and electrode dimensions, are included. C. G. F.

Production of iron and steel in the electric furnace. ALFRED STANSFIELD. *Fuels and Furnaces* 7, 87-95, 251-76(1929).—The author discusses the various types of arc and induction furnaces for melting cold steel, for finishing molten steel and melting gray iron. Details regarding furnace construction, method of charging, slagging and furnace operation are presented together with a description of the various makes of arc melting furnaces. Special reference is made to the Frick furnace (6.5-ton capacity) 700 kw., 5000 v. and 15 to 5 cycles, and the Ajax coreless induction furnace. A. D. S.

The electrometallurgy of die-casting and bearing metals (tin-lead). FRIEDRICH VOGEL. *Metallborse* 18, 1265-6, 1490-1, 1657-8, 1769-70(1928); cf. *C. A.* 22, 3099.—A review. The electrolytic, wet, recovery process for pure Sn and Sn-Pb alloy from Sn-Pb-Sb-Cu alloy scrap and sculls is cheaper than the older, dry, furnace processes. At the end of a preliminary smelting operation the alloy is cast into anodes consisting of 50% Sn, 35% Sb, 10% Cu and 5% Pb. The fluosilicate bath is used; a little sulfate or iodide is added to ensure pptn. and accumulation of the Pb in the anode sludge. The electrolytic Sn-Pb alloy produced is free from Cu and has but 0.5% Sb. C. G. F.

The fundamentals of electroplating. HERBERT KURREIN. *Metallwirtschaft* 7, 314-9(1928); 10 illus.—A review. C. G. F.

Cadmium plating. I. TOSHIO WATANABE and CHORYO TSUCHIMOTO. *J. Mining and Met.* (Japan) 7, 3-10, 34-40(1929).—In plating Cd from cyanide soln. on Fe the current efficiency at the cathode does not change much up to the point of gas evolution, which lies at 1.75 amp./sq. dm. At too low c. d. the deposited metal becomes cryst. The p. d. between the two electrodes increases almost linearly up to the point of gas evolution, but then becomes a little slower; so in practice a wide range of c. d. may be utilized. The concn. has little effect on current efficiency. With the increase of concn., however, the c. d. necessary to obtain a good deposition tends to increase. The p. d. curve varies rapidly at first up to 0.2 N and then increases only very slowly, so that although the time of deposition may be shortened by increasing the concn. there is little difference economically between using a 0.2 N and a 0.5 N  $\text{Cd}(\text{CN})_2$  soln. With const.  $\text{Cd}(\text{CN})_2$  concn. and increasing KCN concn. the c. d. required increases slightly. The character of the deposit is good above 1.5 N KCN, the increase in KCN

causing an increase in the luster of the deposit. In the range over which the p. d. rapidly decreases with the increase of KCN, the deposit becomes cryst., while in the range over which the p. d. decreases only very slowly the deposit becomes uniform and good, so that a considerable excess of KCN is necessary. The optimum temp. is 30°. The presence of carbonate makes the deposit slightly more cryst. but has no effect upon the current efficiency. When EtOH or pyrogallol is added, there is a slight increase of the metallic luster. Gelatin, glue, etc., have no good effect. Peptone has a very good effect and the excess of KCN required may be decreased. Amalgamating the anode did not affect the current efficiency. The range of the c. d. over which the anode dissolves without any particular change is confined within definite limits, the range increasing rapidly with the increase in KCN. Since Zn and Cd act as anode against Fe, even when the covering is incomplete, the electrochem. action prevents corrosion. With Ni, Sn and Cr, the corrosion proceeds further in consequence of galvanic action. The p. d. between Cd and Fe is small and consequently the galvanic action is small, and moreover Cd itself is less readily corroded than Zn, and has a greater covering action upon Fe; hence Cd is concluded to be more effective as a protecting material for Fe.

**The chromium electroplating tank.** KARL A. HERRMANN. *Metal Ind.* (N. Y.) 27, 335-7(1929).—The health and property hazards peculiar to Cr plating are discussed.

E. H.

**Fundamental factors involved in chromium plating.** L. WEISBERG AND W. F. GREENWALD. *Metal Cleaning and Finishing* 1, No. 1, 85-8, 112(1929).—The necessity of technical control in compn. of soln. is discussed; also temp. of operation, c. d., design of racks and cost.

E. I. S.

**Anodic pickling of small metal parts, using an auxiliary (tungsten) anode.** E. FENSKE. *Metallborse* 18, 1322(1928).—The metal parts of incandescent-lamp stems or of radio-tube stems are readily pickled and cleaned by using an auxiliary W anode in an acid bath. For example, the mounted grid is immersed in the dil. acid bath and brought into contact with the W anode. Immediately the voltage drops from 70 to 6 v., in consequence of the oxide film formed on the W anode.

C. G. F.

**Electrolytic preparation of hydrogen.** II. KANJI TERANO AND HIROMICHI SHIMOYAMA. *Bull. Coll. Eng. Kyushu Imp. Univ.* 3, 227-41(1928).—The least corrosion is observed when Ni is used as electrode material; next in order are Ni-plated steel, steel, Co steel and Ni steel. With alkali carbonate solns. the corrosion is rather large. The cathode overvoltage is the lowest with Ni; Ni-plated steel and Co-plated steel are next. The anode overvoltage is in the same order, but is very small. Cathodic overvoltage is less with the more rough surfaces. The increase in the temp causes decrease in the overvoltage. For the electrolyte 20% NaOH is best in respect to gas evolution. In regard to cond. and electrode corrosion it is no different from 15% NaOH soln. With 30% NaOH the p. d. may be decreased, but the corrosion is greater. To prevent mixing of the gases evolved from the 2 electrodes an asbestos diaphragm is better than a diaphragm constructed from glass plates.

K. SOMEYA

**Hydrogen in the electrical industry.** W. R. WHITNEY. *Elec. News* (Toronto) 37, 48-50(1928); *Science Abstracts* 32B, 80; cf. *C. A.* 23, 341.—The first use of H was for the annealing of transformer iron; since then its use has been extended to the production of alloys of W, Mo and other rare metals. Three processes employing H are used in cutting or welding metals: the direct flame, the elec. arc in an atm. of H, and the at. H arc. It is stated that 99% of the frames of large elec. generators are now of welded construction. In brazing, H serves as a flux, as it cleans the surfaces by reducing any oxides to their resp. metals. Melted Cu in the presence of H has the tendency to flow into the narrowest crevices in steel, so that by thus impregnating Fe with Cu it is possible to build vacuum-tight app. Finally, H is coming into use instead of air for cooling elec. generators, on account of its greater heat-dissipating properties.

**Electromotive forces of silver-silver chloride-calomel cells.** W. M. MAZZE. *Ind. Australian and Mining Standard* 81, 352, 372(1929).—An investigation of conditions of prep. Ag-AgCl electrodes reproducible within 0.1 mv. The potentials found varied from 42.2 to 46.6 mv. at 25°; the latter is considered as the real potential.

E. I. S.

**The electrolytic protection of iron.** W. VAN WULLEN-SCHOLTEN. *Metallborse* 19, 1240-1, 1295-6, 1517-20(1929).—The Cumberland process of protecting boilers, etc., from corrosion, by employing an outside elec. current to oppose that produced

locally, has not given satisfaction in certain (German) post-war vessels. Expts. were conducted with smooth and roughened iron electrodes in baths in contact with air, under H, and with air currents led through them. Bauer's recommendation for the protection of Fe in such conditions gives about 0.050–0.067 ma./sq. cm.; in the expts. were used 0.010, 0.025, 0.050 and 0.100 ma./sq. cm. The c. d. 0.010 ma./sq. cm. was insufficient. Under H a c. d. of 0.100 ma./sq. cm. was needed for prolonged protection of the Fe. When air was led through the baths a higher c. d. was needed than when the soln. was quiet, but in contact with air. Losses in wt. of the electrodes were detd. with difficulty. After 20–24 hrs. potentials assumed const. values. The calcd. and actual current densities required for protecting the Fe agreed very well.

R. H.  
Preparation of a stabilized electrode and its application to the determination of the halogens. N. JOASSART AND Ed. LECLERC. *Bull. soc. chim. Belg.* **38**, 121–31 (1929).—The electrode of Oosterheld and Honegger (cf. *C. A.* **13**, 3106) has been simplified. Fill a small glass tube with a hot mixt. contg. 1.62 g. KNO<sub>3</sub> and 0.34 g. NaNO<sub>3</sub> in 10 cc. H<sub>2</sub>O and 5.5 g. gelatin. Insert a small Ag spiral, allow to cool and cut the bottom. For the electrometric titration of the halogens with AgNO<sub>3</sub>, the gelatin electrode is dipped into the soln. to be titrated. The Ag coil constitutes the positive pole, while the negative one is a rotating Ag plate which is used to stir the electrolyte. It is advantageous to titrate in the presence of MnO<sub>2</sub> (except iodides); the acid concn. does not matter; HNO<sub>3</sub> can be substituted for H<sub>2</sub>SO<sub>4</sub>, except when detg. iodides. When the gelatin contracts in its tube, cut the tube to insure a fresh surface of contact. A. L. H.

The preparation of potassium permanganate by electrolysis. J. ROUDNIK. *Bull. soc. chim. Belg.* **38**, 147–59 (1929).—The influence of the following variables on the yield of KMnO<sub>4</sub> formation by electrolysis has been investigated: nature of the electrolytic bath, temp., c. d., anode potential, distance between the electrodes, ratio of the electrode surfaces and nature of the anode. The best results were obtained with a large anode, made of 80% Mn-Fe, a Ni wire as cathode, a short distance between the electrodes, a low temp., and a 7 N K<sub>2</sub>CO<sub>3</sub> electrolytic bath.

ALBERT L. HENNE  
Investigation of the Leclanché cell. I. Behavior of natural and artificial manganese dioxide. V. P. IL'INSKII AND N. P. LAPIN. *Zhur. Prikladnoi Khim.* **1**, 176–80 (1928).—Artificial MnO<sub>2</sub> increases the capacity of the element as compared with the natural MnO<sub>2</sub>. MnO<sub>2</sub> produced by oxidizing a mixt. of MnCl<sub>2</sub> with HNO<sub>3</sub> and KClO<sub>3</sub>, and MnO<sub>2</sub> from electrolysis of manganous salts give best results. MnO<sub>2</sub> prepd. by electrolytic oxidation of MnSO<sub>4</sub> soln. gave almost theoretical figures, and MnO<sub>2</sub> prepd. by reducing KMnO<sub>4</sub> is almost as good, but deteriorates faster. Concn. of MnO<sub>2</sub> in pyrolusites is of little importance. An av. cell loses 1.5–2% of its capacity per month when stored for 5–10 months. Many cells discharged considerably more than the theoretical amt. of energy.

V. KALICHEVSKY  
The electrochemical oxidation of anthracene to anthraquinone with a new type of electrode. C. H. RASCH WITH ALEXANDER LOWY. *Trans. Am. Electrochem. Soc.* **56**, (preprint) 6 pp. (1929).—A new type of electrode consists of a base or framework of metal, which supports the oxide of the metal intimately mixed with an organic depolarizer. Exptl. work was conducted to oxidize anthracene to anthraquinone by using a lead grid filled with a mixt. of PbO<sub>2</sub> and anthracene as the anode. The new type electrode gave a much greater yield and current efficiency than where the depolarizer was suspended in the electrolyte. This principle is recommended with other electrode combinations for org. electrolytic reductions and oxidations.

C. G. F.  
Electrolytic reduction of aromatic arsonic acid. KYUWA NAKADA. *Collected Lectures Inst. Chem. Research (Japan)* **1**, 94–8 (1929).—3,4-O<sub>2</sub>H(HO)C<sub>6</sub>H<sub>3</sub>AsO<sub>3</sub>H<sub>2</sub> is best reduced to H<sub>2</sub>N(HO)C<sub>6</sub>H<sub>3</sub>AsH<sub>2</sub> by 2.6 amp. in 1 1/3 hrs. with 2 g. of the substance in 2 N HCl soln. Variations of c. d. and temp. cause variations in the yield but no change in the resulting product. Optimum temp. is 25°. Above 60° there is some decompn. When the HCl concn. is small arsonic acid compds. are formed, while with more concd. HCl arseno compds. are formed. Arsanilic acid forms arsenoaniline while O<sub>2</sub>N(HO)C<sub>6</sub>H<sub>3</sub>AsO<sub>3</sub>H<sub>2</sub> forms arspenamine above 5 N acid. Phenolarsonic acid becomes arsenophenol at a high acid concn. Arsonic acids are reduced by cathodes of Hg, Pb and Pb-Hg, while with Pt, Ni and Cu cathodes only the nitro radical is reduced to form amino or other intermediate derivs., the yield being proportional to the over-voltage of the electrodes.

Investigations on the electrolytic oxidation of some organic compounds. C. MARIE AND G. LEJEUNE. *J. chim. phys.* **26**, 237–49 (1929); cf. *C. A.* **22**, 4345.—Work

was extended to include secondary alcohols, aromatic amines and phenols. The results confirm the previous work.

ARTHUR FLEISCHER

**Electrochemical oxidation of 1,3-xylene-4-sulfonic acid.** MORIAKI YOKOYAMA. *Helv. Chim. Acta* 12, 756-85(1929).—Anodic oxidation of molar solns. of 1,3,4-Me<sub>3</sub>-C<sub>6</sub>H<sub>3</sub>SO<sub>3</sub>H (I) with 20% H<sub>2</sub>SO<sub>4</sub> as the catholyte, a PbO<sub>2</sub>-Pb anode and a porous clay diaphragm, at 0.04 amp./sq. cm., *T* = 75-80°, results in either (a) oxidation of the side chains with formation of such substances as HCOOH, HOAc, 6-sulfo-*m*-toluic acid, 4-aldehydo-2-sulfobenzoic acid, with 4 sulfoisophthalic acid as the final product or (b) hydroxylation of the nucleus with the intermediate formation of a quinone, subsequent migration of Me group from the 3 to the 2 position and complete oxidation of the nucleus to give dimethylmaleic anhydride (II) (above 75° only) and possibly fumaric acid. That both reactions (a) and (b) may take place together is indicated by the identification of 5,6-dihydroxy-4-sulfo-*m*-toluic acid (III). Use of a Pt anode gives only II and III as products. Anodic oxidation of xyloquinone (IV) yields 2,3-dimethylmaleic acid as one of the products, whereas 1,3,6,4-Me<sub>4</sub>(HO)C<sub>6</sub>H<sub>2</sub>SO<sub>3</sub>H (V) yields both II and III, indicating that IV and V must be regarded as possible intermediates in the electrochem. oxidation of I. The formation of a peroxide or a peracid which enhances the anodic effect is postulated to account for the variety of products and the completeness with which both oxidation of the side chains and hydroxylation of the nucleus take place.

**Storage batteries.** A. POUCHAIN. Brit. 303,823, Jan. 10, 1928. A battery electrode on which Zn is to be deposited consists of a support of metal (such as brass or Cu coated with Ag) which is a better conductor than Zn, covered with Zn where the latter is to be deposited and elsewhere with an insulating varnish or rubber or other suitable material. For storage, the electrode may be coated with a soln. of Na silicate and gum arabic which dissolves when the electrode is immersed in the electrolyte. Brit. 303,824 specifies structural features of a battery with Pb plates. Cf. C. A. 22, 3590.

**Preparing storage batteries for service.** W. H. GRIMDITCH (to Philadelphia Storage Battery Co.). U. S. 1,722,210, July 23. The battery is treated with steam and electrolyte is then supplied to replace the steam in the pores of the battery plates and separators.

**Battery jar of vulcanized rubber.** JAMES H. WAGENHORST. U. S. 1,722,650, July 30. Structural features.

**Liquid for filling storage batteries prior to charging.** GUSTAV SCHMAUS. U. S. 1,722,343, July 30.  $\text{H}_2\text{SO}_4$  is used with  $\text{NH}_4$  and Al salts such as the sulfates and with a basic acetate such as that of Al which serve to facilitate rapid charging.

**Electrodeposition of metals in powdered form.** SOC. ANON. TREFILERIES ET LAMINOIRS DU HAVRE, ANCIENS ÉTABLISSEMENTS L. WELLER, SOC. COOPÉRATIVE DE RUGLES, ET LA CANALISATION ÉLECTRIQUE REUNIS. Brit. 303,984, Dec. 3, 1927. In effecting the deposition of metals such as Cu, Zn, Cd, Sn, Pb, etc., a carbonized compd. in a state of dispersion as near as possible a colloidal soln. (such as glucose carbonized with  $\text{H}_2\text{SO}_4$  or finely divided "sugar charcoal") is added to the electrolyte.

**Electrodeposition of chromium.** SOC. NOUVELLE DE L'ORFÈVRERIE. Brit. 303,884, Jan. 12, 1928. The electrolyte is formed from  $\text{NaHCO}_3$ , chromic acid and chromic fluoborate, with or without a small addition of fluoboric acid. Pb or Cr anodes may be used.

**Electrodeposition of lead from solutions containing ferrous chloride.** S. I. LEVY and G. W. GRAY. Brit. 304,054, Feb. 10, 1928. Solns. such as those obtained by treating with HCl the product derived from iron pyrites by heating in the absence of air or by treatment with Cl, and contg. Pb with high concns. of  $\text{FeCl}_2$  are electrolyzed; an iron anode and an e. m. f. less than that required to decompose the  $\text{FeCl}_2$  are used. Various details and modifications of the process are described.

**Electroplating apparatus.** ALBERT H. HANNON. U. S. 1,723,480, Aug. 6. Structural features.

**Apparatus for electroplating annular articles with nickel or other metals.** DUNLOP RUBBER CO., LTD., and H. TREVASKIS. Brit. 304,029, Jan. 19, 1928. Structural features.

**Electroplating with aluminum.** DANIEL GRAY, RICHARD O. BAILEY and W. S. MURRAY (to Oneida Community, Ltd.). U. S. 1,723,277, Aug. 6. A material to be coated is used as cathode with an anode of Al and an electrolyte comprising an Al salt of an aminobenzenesulfonic acid.

**Plating and polishing anode for refinishing plated metal articles in situ.** PHILIP E. EDELMAN. U. S. 1,721,949, July 23. Substances such as Ni and  $\text{NH}_4$  sulfates,  $\text{MgSO}_4$ ,  $\text{NH}_4\text{Cl}$  and  $\text{H}_3\text{BO}_3$  are held within a fabric cover together with a polishing powder such as infusorial earth. In use, the electrode is applied as a rubbing pad.

**Electrolysis of dilute electrolytes while heated.** E. CITOVICH. Brit. 303,027, Dec. 24, 1927. Electrolytic processes are carried out with a dil. electrolyte at a temp. between  $100^\circ$  and the crit. temp. so that the processes are reversible, e. g., an alk. soln. is electrolyzed at  $300^\circ$  to produce H and O which are collected in high-pressure receivers initially filled with steam; by slightly raising the temp. the steam pressure is raised

so as to cause gas to reënter the electrode chambers whereupon the reaction is reversed and the app. functions as a galvanic battery. The anode may be in contact with CO or other reducing gas or vapor or with an org. substance such as an oil which is oxidized by the electrolytic action. Gaseous fuel may be formed from solid or liquid fuels. In generating O an electrode of ferric or Cu oxide is suitable. Precious metals, alloys, iron, Ni, oxides, sulfides and graphite also may be used as electrodes.  $\text{CaCl}_2$  may be dissolved in the electrolyte to reduce the vapor pressure. C, Br and I may be produced and  $\text{PhNO}_2$  reduced to  $\text{PhNH}_2$  by the process. An app. is described.

**Electrolyzing ferrous chloride solutions.** S. I. LEVY and G. W. GRAY. Brit. 304, 053, Feb. 10, 1928. A concd. soln. of  $\text{FeCl}_2$  is electrolyzed at a temp. of 90–100° in a cell comprising an anode of C or the like in a compartment contg. a concd. soln. of  $\text{NaCl}$ ,  $\text{CaCl}_2$ ,  $\text{MgCl}_2$  or other chloride of a metal which forms only one chloride. The  $\text{FeCl}_2$  flows through the cell at such a rate that the issuing spent liquor contains 20%  $\text{FeCl}_2$ . Fe is deposited on the cathode. Various other details of app. and of procedure are described.

**Electrolytic rectifier.** WILLIAM H. GRIMDITCH (to Philadelphia Storage Battery Co.). U. S. 1,723,154, Aug. 6. Electrodes of Al and an Fe alloy contg. not less than 10% Si are used with an electrolyte soln. comprising monobasic K phosphate, dibasic  $\text{NH}_4$  phosphate and malic acid. U. S. 1,723,155 specifies a soln. of an alkali metal phosphate, an org. acid such as malic acid and a substance contg. the benzoate radical such as Na benzoate. Cf. C. A. 23, 346.

**Electrolytic cell suitable for rectifiers, condensers, lightning arresters, etc.** ISRAEL A. SHULIMSON (to American Bosch Magneto Co.). U. S. 1,721,886, July 23. A cathode comprising Al is used with an anode which may be formed of Cr-Ni steel and an electrolyte contg. a neutralized soln. of  $\text{NH}_4$  phosphate and  $\text{K}_2\text{Cr}_2\text{O}_7$ .

**Aluminum and its alloys.** A. PACZ. Brit. 303,755, Jan. 7, 1928. Compsds of 2 or more of the alkali metals such as Na, K or Li are used in the charge for producing Al or its alloys by electrolytic or electrothermal methods. Alloys with Ti, Zr, B and Si are referred to, and various details are given.

**Tungsten alloys.** OSCAR L. MILLS. U. S. 1,721,966, July 23. In carrying out a continuous process, a W compd. including W oxide 3–20% is mixed with reclaimed W carbide alloy and metallic W 15–20% and the mixt. is fused by a C elec. arc; waste material from the product is reclaimed in the form of W carbide and at least a portion of the reclaimed waste material is oxidized to form W oxide, which is used for continuing the process. An app. is described.

**Electric furnace for magnetizable metals.** LOUIS D. J. TISSEYRE. Fr. 657,895, Nov. 23, 1927.

**Electric furnace for producing glass, water glass, cement or phosphates.** C. E. CORNELIUS. Brit. 303,798, Jan. 9, 1928. See Can. 283,657 (C. A. 22, 4391).

**Electric resistance furnace adapted for heat treatments.** FRANK T. COPE and ROLAND F. BENZINGER (to Electric Furnace Co.). U. S. reissue 17,388, July 30. See original pat. 1,647,726 (C. A. 22, 196).

**Electric resistance furnace suitable for heating the ends of rock drills.** A. IMBERY. Brit. 303,222, Oct. 10, 1927. Structural features are described of a furnace having automatic temp. control.

**Electric resistance-heated furnace suitable for heat treatment of steel.** IRVING B. SMITH (to Leeds & Northrup Co.). U. S. 1,721,840, July 23. Structural features.

**Electric resistances.** THOMAS S. KEMBLE (to Universal Gas Electric Co.). U. S. 1,721,910–11, July 23. Structural features.

**Electric resistance heater of the enclosed wire type.** R. A. F. JACKSON and J. D. PLACE. Brit. 303,606, Nov. 8, 1927. Structural features.

**Electric resistance heated oven with thermostatic control.** C. HAWKINS. Brit. 303,280, Jan. 13, 1928. Structural features.

**Electrode for electric furnaces.** MATHIAS O. SEM (to Norske Aktieselskab for Elektrokemisk Industri). U. S. 1,723,582, Aug. 6. See Fr. 646,310 (C. A. 23, 2110).

**Electrode for electric "luminous" arc lamps.** W. IRBY (to General Elec. Co.). U. S. 1,722,146, July 23. Electrodes are formed of ilmenite 69.0, chromite 3.0, magnetite 14.92, NaF 0.28 and ferro-Ti 12.8%. Cf. C. A. 22, 2116.

**Electric cables.** BELL TELEPHONE LABORATORIES, INC. Brit. 303,561, Oct. 6, 1927. In making a loaded signalling cable a tape of magnetic material such as an alloy of Ni or Fe is wound on a Cu core and adhesion to the latter is prevented by an intermediate coating on the core formed of a metal such as Ni having a m. p. above the annealing temp. of the magnetic wrapping. Various details of manuf. are given.

**Promoting various chemical reactions by high-frequency electric currents.** O.

ARENDET. Brit. 303,822, Jan. 10, 1928. An app. is described in which reactions are effected by high-frequency currents by producing a cloud of dust particles (such as iron or Fe oxide) between the high-frequency electrodes, the dust particles producing spark fields for the "working current." The method is stated to be suitable for use in forming compds. of N and P, forming complex products from CO and H, steam or CH<sub>4</sub>, condensation of isoprene and synthesis of NH<sub>3</sub>.

**Incandescent cathode-discharge tube.** N. V. PHILIPS' GLOELAMPENFABRIEKEN. Fr. 657,936, July 21, 1928.

## 5—PHOTOGRAPHY

C. E. K. MEES

**Mechanical action on the photographic plate.** A. REYCHLER. *Bull. soc. chim. Belg* 38, 168-71 (1929).—The statements made by R. (C. A. 20, 1361) that the rubbing of a blunt metal or glass stylus would be shown by a black trace after development having been challenged by Berthoud (*Photochimie*, 299; cf. C. A. 22, 732), R. has repeated his expts. with a variety of materials and plates. He again finds that AgBr emulsions are affected by mechanical contact and are very sensitive to it, whereas AgCl emulsions are very much less affected. An explanation is proposed to account for the similar effect of mechanical pressure and light on the AgBr grains.

ALBERT L. HENNE

**Studies in photographic sensitivity. V. Effects of heat on the absorption spectrum and photo-electric conductivity of silver bromide, and their relation to the photographic action.** O. MASAKI. *Mem. Coll. Sci. Kyoto Imp. univ.* 12A, 127-34 (1929).—Increase in temp. of the Ag halides caused an extension of the absorption spectrum toward the red. The max. in the photoelec. cond. curve of AgBr was also displaced towards the same side on raising the temp. Heat affects the absorption and photoelec. cond. of AgBr in a way similar to its effect on the photographic action, indicating a close connection among these 3 phenomena.

W. VANSELOW

**The sensitivity of photographic emulsions.** K. CHIRISOV. *Zhur. Prikladnoi Khim.* 1, 37-53 (1928).—Graphical comparison of the sensitivity units of Eder-Scheiner, Hurter and Driffield, Eder-Hecht, and Chapman-Jones.

V. KALICHEVSKY

**Primary process in the formation of the latent photographic image.** S. E. SHEPPARD. *Nature* 123, 979-80 (1929).—The hypothesis of liberation of electrons from AgBr, by light, is now well substantiated. It appears desirable, however, to emphasize that the primary process is limited to the sepn. of the electron from the bromide ion. The formation of a latent or visible image is detd. by the processes immediately following. Formation of the latent image involves both the segregation of Br and the aggregation of the Ag atoms produced.

E. W. H. S.

**Physical development and the nature of the latent image.** R. F. OWEN. *Phot. J.* 69, 278-80 (1929).—Lumière and Seyewetz believed that they had shown that the latent image was not composed of metallic Ag, on the basis of some expt. in which CH<sub>2</sub>O was found incapable of phys. development unless development had been initiated by another developer (amidol, metol-hydroquinone, etc.). Kieser (C. A. 23, 2894), however, has shown that the image of a plate, fixed in thiosulfate, consists to a large extent of Ag<sub>2</sub>S, which probably exerts a protective effect on the original latent image of Ag. If this be true, the results of Lumière and Seyewetz should be exactly reproducible with suspensions of colloidal Ag<sub>2</sub>S in gelatin, and this is found to be the case. Their expt., therefore, cannot be regarded as disproving the metallic Ag theory of the latent image.

E. W. H. S.

**Fixation.** F. F. RENWICK. *Phot. J.* 69, 310-4 (1929).—The nature of the reactions involved in the removal of Ag halides from an emulsion by Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is briefly considered. The activity of every hypo bath depends not only on the amt. of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> it contains, and its temp., but on the amt. of Ag salts which have already been dissolved in it. Curves show the effects of concn. of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, of temp., and of increasing amt. of dissolved Ag halides. The effect of addn. of KBr is shown, and also the relation between coating wt and fixing time. The various factors influencing the rate of fixation are enumerated.

A. BALLARD

**Chemistry of fixation.** H. BAINES. *Phot. J.* 69, 314-7 (1929).—The complex Ag-Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> formed as intermediate and final products in the reactions between Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> and Ag halides have been isolated and their formulas found to be, resp., Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>-Ag<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O (or more probably NaAgS<sub>2</sub>O<sub>3</sub>·H<sub>2</sub>O) and Na<sub>3</sub>Ag<sub>2</sub>(S<sub>2</sub>O<sub>3</sub>)<sub>4</sub>·2H<sub>2</sub>O. In soln. of these salts, the Ag is present almost wholly in the form of the anions AgS<sub>2</sub>O<sub>3</sub><sup>-</sup> and

$\text{Ag}_3(\text{S}_2\text{O}_3)_4$ . A slight secondary dissocn. of the former ion is postulated, giving rise to a small concn. of Ag cations. The satn. point of the bath is reached when the product of the Ag cation and halide anion concn. attains a value equal to the soly. product of the Ag halide.

**Methods of sulfide toning.** P. WIEGLEB. *Brit. J. Phot.* **76**, 363-5(1929); cf. *C. A.* **23**, 3865. The compn. and efficiency of bleaching baths are considered. Bleaching soln. contg. Cu, Hg or Pb ferrocyanide will in many cases produce a considerable intensification of the image through formation of the corresponding sulfides, which mask the individual color of the  $\text{Ag}_2\text{S}$ . Various sulfiding baths are described, including  $\text{Na}_2\text{S}$ ,  $(\text{NH}_4)_2\text{S}$ , BaS, liver of sulfur,  $\text{Na}_3\text{SbS}_4$ .

**Selenium toning processes.** A. SEDLACZEK. *Brit. J. Phot.* **75**, 784-5; **76**, 1-6, 29-31, 44-6(1929); *Phot. Ind.* **26**, 1190-2, 1218-20, 1247-9(1928).—S. reviews in detail the chemistry of many Se compds. and their suitability for toning purposes. Analogous *Te compds.* and *S compds.* also are discussed. An extensive description is included of references, including patents.

**Solarization and denucleation.** LÜPPO-CRAMER. *Kinotechnik* **11**, 285-7(1929).—L.-C. describes some results of over-exposure in the first reversal of the solarization of photographic plates before and after treatment with chromic acid. Two photographic emulsions, pptd. with different excesses of  $\text{NH}_4\text{Br}$ , gave entirely different results. This fact is explained by differences in the structure of the Ag halide grains.

**Prevention of the Herschel effect by silver ions.** LÜPPO-CRAMER. *Phot. Ind.* **27**, 662(1929); cf. *C. A.* **20**, 2290.—L.-C. has made expts. with AgBr collodion emulsion, which gives excellent Herschel effects. After a diffused pre-exposure and a bath of 1%  $\text{AgNO}_3$  and 1% citric acid no further Herschel effect could be detected. L. C. considers that this observation supports the regression theory of the Herschel effect. The collodion emulsion also gave a Herschel effect under yellow and blue glass.

A. P. H. TRIVELLI

**Handbuch der wissenschaftlichen und angewandten Photographie. Band III. Photochemie und photographische Chemikalienkunde.** Edited by A. Coehn, G. Jung and J. Daimer. Vienna: Verlag von Julius Springer 296 pp. M. 28; bound, M. 30.80.

WALL, EDWARD J.: **Photographic Emulsions.** Their preparation and coating on glass, celluloid and paper, experimentally and on the large scale. Boston: American Photographic Pub. Co. 256 pp.

**Color photography.** UNION PHOTOGRAPHIQUE INDUSTRIELLE ET ÉTABLISSEMENTS LUMIERE ET JOUGLA RÉUNIS. Fr. 657,902, Dec. 2, 1927. Colored particles for making multicolor screens are produced by dyeing threads of artificial silk, embedding them in paraffin wax, feeding them to a microtome, and dissolving the wax from the particles so produced by  $\text{C}_6\text{H}_6$ ,  $\text{CCl}_4$ , trichloroethylene, etc. The screen is made by spreading a mixt. of such particles of 3 or more colors on a plate or film coated with an adhesive and rolled. Any interstices may be filled with fine charcoal, etc.

**Color screens (with dyed solutions) for use in color photography.** SOC. CIVILE POUR L'ÉTUDE DE LA PHOTOGRAPHIE ET DE LA CINÉMATOGRAPHIE EN COULEURS (to Soc. française cinéchromatique procédés R. Berthon Soc. anon.). *Brit.* 303,170, Dec. 30, 1927. Structural features.

**Photographic method of preparing printing blocks or plates for wood grain finishes.** KOCH & KIENZLE (to Masa Ges. zur Herstellung künstlicher Oberflächen). *Brit.* 303,804, Jan. 9, 1928.

**Light-sensitive material.** KALLE & Co. A.-G. Fr. 657,851, July 20, 1928. See *Brit.* 294,247 (*C. A.* **23**, 1832).

**Cinematograph film material.** P. REHLÄNDER. *Brit.* 303,752, Jan. 5, 1928. A celluloid support has mixed throughout its mass a material of a high degree of whiteness such as  $\text{MgO}$ , white lead or lithopone so that a high proportion of incident light is transmitted with the strongest possible dispersion. *Brit.* 303,794 relates to somewhat similar film supports. Cf. *C. A.* **23**, 1072.

**Developing and finishing photographic films.** J. E. THORNTON. *Brit.* 303,262, Dec. 6, 1927. In producing a series of relief images of hardened colored colloid upon a continuous film which has been printed by exposure to light until portions of its colloid layer have been rendered insol., the film is treated with solvents to remove sol. colloid in 2 or more stages, and there is then applied to the film a bath or spray of a hardening agent such as alum or  $\text{CH}_2\text{O}$  soln. An app. is described.

## 6—INORGANIC CHEMISTRY

A. R. MIDDLETON

**Germanium. XXX. Halogen substitution products of monogermane.** L. M. DENNIS AND P. R. JUDY. *J. Am. Chem. Soc.* **51**, 2321-7(1929).— $\text{GeH}_3\text{Cl}$  and  $\text{GeH}_2\text{Cl}_2$  were prepd. by reaction of  $\text{GeH}_4$  and  $\text{HCl}$  in the presence of  $\text{AlCl}_3$ ; they were sepd. by fractionation and some of their chem. and phys. properties studied.  $\text{GeH}_3\text{Cl}$ , m.  $-52^\circ$ , b.  $28^\circ$ ,  $d_{20} 1.75$ .  $\text{GeH}_2\text{Cl}_2$ , m.  $-68^\circ$ , b.  $69.5^\circ$ ,  $d_{20} 1.90$ . The corresponding Br compds. were obtained in an analogous manner.  $\text{GeH}_3\text{Br}$ , m.  $-32^\circ$ , b.  $52^\circ$ ,  $d_{20} 2.34$ ,  $\text{GeH}_2\text{Br}_2$ , m.  $-15^\circ$ , b.  $89^\circ$ ,  $d_{20} 2.80$ , begins to decompose at  $50^\circ$ . Similar reaction with  $\text{HI}$  gave  $\text{GeI}_2$ ,  $\text{GeI}_4$  and  $\text{H}_2$ , as end products, the iodine substitution products being quite unstable. T. H. CHILTON

**Metal carbonyls.** ROBERT L. MOND. *Chimie et industrie* **21**, 681-700, 937-40 (1929).—An address reviewing the prepn., properties and applications of metallic carbonyls, with a bibliography of 91 references to articles, 51 to Brit. pats., 3 to Can. pats., 4 to Fr. pats., 3 to Ger. pats. and 8 to U. S. pats. A. PAPINEAU-COUTURE

**Univalent iron, cobalt and nickel. V. The formation of nickel carbonyl.** W. MANCHOT AND H. GALL. *Ber.* **62B**, 678-81(1929); cf. *C. A.* **23**, 785.—When  $\text{Ni}(\text{NO})_2 \cdot 6\text{H}_2\text{O}$  is treated with  $\text{CO}$  at  $100-140^\circ$ ,  $\text{NO}$  is replaced by  $\text{CO}$  with formation of  $\text{Ni}(\text{CO})_4$ . A better yield is obtained when  $\text{CO}$  is allowed to act upon an alk. mixt. of  $\text{NiSO}_4$  and  $\text{C}_2\text{H}_5\text{SH}$  or one of  $\text{NiSO}_4$  and  $\text{KSH}$  in water. In the latter case the reaction may be represented by the equation:  $\text{Ni}(\text{SH})_2 + 4\text{CO} = \text{Ni}(\text{CO})_4 + \text{S}_2\text{H}_2$ ; it is probable that an intermediate product is formed according to:  $2\text{Ni}(\text{SH})(\text{CO})_n \longrightarrow \text{Ni}(\text{SH})_2 + \text{Ni}(\text{CO})_4$ . VI. **Compounds containing iron, sulfur and nitrogen oxide.** W. MANCHOT AND S. DAVIDSON. *Ibid.* 681-7.—When  $\text{FeSO}_4$  in 50%  $\text{EtOH}$  is satd. with  $\text{NO}$  at  $0^\circ$  and a soln. of K xanthate added, dinitrosoferrous xanthate,  $\text{Fe}(\text{NO})_2(\text{S.CS.OC}_2\text{H}_5)_2$ , is formed; it is purified by crystn. from  $\text{CS}_2$ . The paper contains a survey of work which points to the existence of univalent compds. of Fe, Co and Ni. E. K.

**The action of mercury salts on iron pentacarbonyl. II.** H. HOCK AND H. STUHL-MANN. *Ber.* **62B**, 431-7(1929); cf. *C. A.* **23**, 351.—When  $\text{HgSO}_4$  in 10%  $\text{H}_2\text{SO}_4$  is treated with  $\text{Fe}(\text{CO})_5$  at room temp. with continuous shaking,  $\text{Fe}(\text{CO})_4\text{Hg}$  forms in a yield of 85%; it is obtained in a pure state by washing with dil.  $\text{HCl}$ ,  $\text{H}_2\text{O}$  and acetone. The same compd. is obtained together with metallic Hg when  $\text{Hg}_2\text{SO}_4$  is used. No  $\text{H}_2\text{S}$  is pptd. from this compd. by  $\text{H}_2\text{S}$ . I in  $\text{CS}_2$  leads to  $\text{Fe}(\text{CO})_4\text{I}_2$ .  $\text{CuCl}_2$  reacts with both  $\text{Fe}(\text{CO})_5$  and  $\text{Fe}(\text{CO})_4\text{Hg}$  with liberation of  $\text{CO}$  and formation of  $\text{FeCl}_2$ . From  $\text{Fe}(\text{CO})_4\text{Hg}$  and  $\text{HgSO}_4$  the double compd.  $\text{Fe}(\text{CO})_4\text{Hg.HgSO}_4$  is formed. The double compds.  $\text{Fe}(\text{CO})_4\text{Hg.HgBr}_2$  and  $\text{Fe}(\text{CO})_4\text{Hg.HgI}_2$  are obtained from the corresponding Hg halides. Hg acetate reacts with formation of  $\text{Fe}(\text{CO})_4\text{Hg.Hg(OOCC}_2\text{H}_5)_2$ . EMIL KLARMANN

**The existence of higher oxides of nitrogen.** H. J. SCHUMACHER AND G. SPRENGER. *Z. anorg. Chem.* **42**, 697-700(1929).—By supplementing the findings of Raschig and Prahl (*C. A.* **23**, 2787) concerning the non-existence of higher oxides of N, it is shown that  $\text{NO}$  must exist as an intermediate product in the reaction of  $\text{N}_2\text{O}_5$  and  $\text{O}_2$ , being considered as a "chain reaction" and treated from the standpoint of chem. kinetics. On the contrary, when  $\text{NO}$  and  $\text{O}_2$  react no such compd. as  $\text{NO}_3$  is found. W. C. E.

**The preparation of antimony-free arsenious oxide and the estimation of minute amounts of antimony in arsenious oxide.** C. W. FOULK AND P. G. HORTON. *J. Am. Chem. Soc.* **51**, 2416-9(1929).—By treating 150 g. of  $\text{As}_2\text{O}_3$  with 350 cc. of concd.  $\text{HCl}$  and distg. in a stream of  $\text{HCl}$ , a distillate is obtained consisting of an oily layer of  $\text{AsCl}_3$  and a layer of  $\text{HCl}$  and water. By shaking the oily layer with  $2/3$  of its vol. of concd.  $\text{HCl}$ , the trace of  $\text{SbCl}_3$  present is completely dissolved in the acid layer. By treating the acid layer with  $\text{H}_2\text{S}$  all As present is pptd. as  $\text{As}_2\text{S}_3$ . Then, after filtering and dilg. with 3 vols. of water,  $\text{H}_2\text{S}$  will give an orange ppt. of  $\text{Sb}_2\text{S}_3$  if any Sb is present. The test will indicate 0.001% of Sb. By slowly adding the oily  $\text{AsCl}_3$  to considerable boiling water, pure  $\text{As}_2\text{O}_3$  can be obtained by hydrolysis. W. T. H.

**Studies on cobalt oxides and their systems with oxygen.** M. LEBLANC AND F. MORIER. *Z. physik. Chem., Abt. A*, **142**, 151-76(1929).—There is much confusion in the literature regarding Co oxides. LeB. and M. prepd. pure  $\text{CoO}$  by decomp. the carbonate *in vacuo* at  $320-460^\circ$ ; the method is more feasible and satisfactory than the older ones. This oxide has the property of absorbing oxygen to give a compd.  $\text{CoO} \cdot n\text{O}_2$  without change in structure as detd. by chem. and x-ray analysis. This complex when heated at  $100^\circ$  goes over into  $\text{Co}_3\text{O}_4$ , a well-defined compd.  $\text{Co}_3\text{O}_4$  also absorbs  $\text{O}_2$  to give a complex without change in structure.  $\text{Co}_2\text{O}_3$  cannot be prepd. in the dry

way but only by pptn. from a soln. of  $\text{Co}^{++}$  by  $\text{OH}^-$  ion.  $\text{Co}_3\text{O}_4 \cdot n\text{H}_2\text{O}$  when heated gives  $\text{O}_2$  and  $\text{Co}_3\text{O}_4$ ;  $\text{Co}_3\text{O}_4 \rightleftharpoons 3 \text{CoO} + \frac{1}{2} \text{O}_2$ ; the system  $\text{Co}_3\text{O}_4 \cdot n\text{H}_2\text{O}$  is divariant. At  $1250^\circ$  the dissocn. pressure of  $\text{CoO}$  is less than 0.1 mm. Hg. The  $\text{O}_2$  evolved from these complexes is capable of oxidizing oxalic acid in the presence or absence of  $\text{H}_2\text{SO}_4$ .  $\text{Co}_2\text{O}_3$  and  $\text{Co}_3\text{O}_4$  also react quantitatively with oxalic acid. The solution of  $\text{Co}_3\text{O}_4$  in  $\text{H}_2\text{C}_2\text{O}_4$  is accelerated by the presence of  $\text{H}_2\text{SO}_4$ , although otherwise it is very slow.  $\text{Co}^{++}$  hastens the oxidation of oxalic acid by atm.  $\text{O}$  at  $100^\circ$ . WILLIAM E. VAUGHAN

**The crystal structure of tricalcium aluminate.** F. A. STEELE AND WHEELER P. DAVY. *J. Am. Chem. Soc.* **51**, 2283-93(1929).—Tricalcium aluminate is a mixed ionic compd.; its most probable crystal structure is given. The method of prepn. is described.

J. B. AUSTIN

**Hydrated polycalcium aluminates.** A TRAVERS AND SCHNOUTKA. *Compt rend* **188**, 1677-9(1929).—The ppt. formed when solns. of  $\text{Ca}(\text{NO}_3)_2$  and K aluminate (cf. C. A. **22**, 3850) are allowed to react vary in compn. as well as in cryst. form with increasing alkali of the soln. At  $p_{\text{H}}$  11.62-11.79 there are produced spherical groups of crystals,  $\text{Al}_2\text{O}_3 \cdot 3.75\text{CaO}$ ; at  $p_{\text{H}}$  11.79-11.89, hexagonal crystals; above  $p_{\text{H}}$  11.89, hexagonal crystals and rhombohedra of  $\text{Ca}(\text{OH})_2$ . All contain more  $\text{CaO}$  than the *tricalcium aluminate*,  $3\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 21\text{H}_2\text{O}$  (I), despite similarity in cryst. form. These various ppts. are believed to be solid solns. of varying amts. of  $\text{CaO}$  in I. The free  $\text{CaO}$  is much more rapidly dissolved from the dehydrated powd. substance by 6 N  $\text{HCl}$  than I; hence after repeated treatment the residue is I. T. and S. question the existence of *bi-calcium aluminate hydrate* described by Allen and Rogers.

E. R. SCHIERZ

**The preparation of anhydrous hydrogen iodide.** ROBERT T. DILLON AND WILLIAM G. YOUNG. *J. Am. Chem. Soc.* **51**, 2389-91(1929).—Four methods of prep. anhyd.  $\text{HI}$  are compared. The method recommended is to drop concd.  $\text{HI}$  on  $\text{P}_2\text{O}_5$ , bubble through satd.  $\text{CaI}_2$ , dry with  $\text{P}_2\text{O}_5$  and cool to  $-30^\circ$ .

GERALD M. PETTY

**Reaction of cupric salts with thiosulfate.** J. HANUS AND V. HOVORKA. *Collection Czechoslov. Chem. Comm.* **1**, 65-82(1929).—Boiling  $\text{Cu}^{++}$  salt solns. with thiosulfate gave ppts. consisting of a mixt. of varying percentages of  $\text{Cu}_2\text{S}$  and  $\text{CuS}$ . The compn. depends on the duration of the boiling, the amt. of thiosulfate and the acidity. Tabulated data are given.

R. C. ROBERTS

**Formation of acid lithium aluminate.** D. PROCIV. *Collection Czechoslov. Chem. Comm.* **1**, 95-103(1929).—When  $\text{Al}$  dissolves in  $\text{LiOH}$ , an acid lithium aluminate is obtained. These solns. were studied by conductance and cryoscopic methods to explain the phenomenon of supersatn. Before pptn. takes place the  $\text{Al}$  is mainly in the form of normal aluminate ions. Soly. of acid lithium aluminate detd. by conductance at  $25^\circ$  is  $1.2 \times 10^{-4}$ , at  $80^\circ$ ,  $3.3 \times 10^{-4}$  g. equiv. per l. Detection and detn. of  $\text{Li}$  are possible by pptg. the acid lithium aluminate by  $\text{Al}$  salt soln. from solns. alk. with  $\text{NaOH}$  or  $\text{KOH}$ .

R. C. ROBERTS

**The capacity of certain complex saturated compounds for further addition.** O. E. ZVYAGINTZEV. *J. Russ. Phys.-Chem. Soc.* **61**, 515-9(1929).—Satd. salts of the types  $[\text{Me}^{\text{IV}}\text{X}_6] \text{R}_2$  and  $[\text{Me}^{\text{III}}\text{X}_6] \text{R}_3$  may add mols. of water, e. g.,  $[\text{IrCl}_6] \text{Na}_2 \cdot 12\text{H}_2\text{O}$  and  $[\text{RhCl}_6] (\text{NH}_4)_3 \cdot \text{H}_2\text{O}$ . Compds. other than  $\text{H}_2\text{O}$ , e. g.,  $\text{NH}_4\text{NO}_3$  may be added. The elec. cond. of  $[\text{RhCl}_6] (\text{NH}_4)_3 \cdot \text{NH}_4\text{NO}_3$  (I) (C. A. **21**, 868) in aq. soln. was detd. at several concns. As the salt is unstable, it must be dissolved with caution. The mol. cond. changes only slightly as the solns. stand, after 49 hrs. with a 4 M soln. the cond. changed only 2.9%. To make sure that the salt in soln. had not decompd. control expts. were made with boiled solns., when the conds. were always decidedly higher and changed appreciably on standing. The data thus obtained confirm the earlier expl. findings that I dissociates in soln. into five ions, one of which is bivalent. Since the three  $\text{NH}_4$  groups are replaceable by  $\text{Ag}$ ,  $\text{Pb}$  or  $\text{Hg}$ , by double decompn., while the  $\text{NH}_4\text{NO}_3$  remains intact, it follows that three of the five ions are  $\text{NH}_4^+$ . That the remaining univalent ion is nitrate and not  $\text{NH}_4^+$  is shown by quant. pptn. with nitron. The bivalent ion then consists of the remaining groups,  $\text{RhCl}_6\text{NH}_4^-$ , and I may be formulated

as follows: 
$$\begin{array}{c} \text{NH}_4 \left[ \begin{array}{cc} \text{Cl} & \text{Cl} \\ \text{Cl} & \text{Rh} & \text{Cl} \\ \text{Cl} & & \text{Cl} \end{array} \right] \text{NO}_3 \cdot \text{NH}_4 \left[ \begin{array}{cc} \text{Cl} & \text{Cl} \\ \text{Cl} & \text{Cl} \end{array} \right] \text{NH}_4 \end{array}$$

The possibility of the existence of a secondary center of complex-formation in complex compds. is thus confirmed.

I. W. B.

**Complex oxalates of quadrivalent molybdenum.** HENRY M. SPITTLE AND WILLIAM WARDLAW. *J. Chem. Soc.* **1929**, 792-9; cf. C. A. **23**, 2898.—Contrary to expectations, the previously known oxalate of quadrivalent  $\text{Mo}$ ,  $\text{MoO}(\text{C}_2\text{O}_4) \cdot 3\text{H}_2\text{O}$ , is not satisfactorily formulated as the dibasic acid,  $\text{H}_2[\text{MoO}_2(\text{C}_2\text{O}_4)] \cdot 2\text{H}_2\text{O}$ , but rather as  $\text{H}_2[\text{Mo}_2\text{O}_7(\text{C}_2\text{O}_4)_3 \cdot x\text{H}_2\text{O}]$ , a member of the series  $\text{R}_2[\text{Mo}_3\text{O}_{10}(\text{C}_2\text{O}_4)_3 \cdot 5\text{H}_2\text{O}]$ . New members of this series, where  $\text{R} = \text{K}$ ,  $\text{NH}_4$  or  $\text{C}_6\text{H}_5\text{N}$ , have been prepd. and their formulation as

ternary electrolytes has been confirmed by mol. cond. detns. The method is that previously described by Wardlaw, Nicholls and Sylvester (cf. C. A. 19, 20), and Wardlaw and Parker (cf. C. A. 19, 2609) with special precautions to remove  $\text{NH}_3$  and  $\text{NH}_4$  salts as completely as possible. Alc. added to the molybdenyl oxalate soln., the so-called "Solution A," resulted in a clear blood-red soln. from which the various complex oxalates were obtained by the addn. of the appropriate base. *Dipyridinium trimolybdenum-tetroxytrioxalate*,  $(\text{C}_5\text{H}_5\text{N})_2[\text{Mo}_3\text{O}_4(\text{C}_2\text{O}_4)_3 \cdot 5\text{H}_2\text{O}]$ , *dipotassium trimolybdenum-tetroxytrioxalate*,  $\text{K}_2[\text{Mo}_3\text{O}_4(\text{C}_2\text{O}_4)_3 \cdot 5\text{H}_2\text{O}]$  and *diammonium trimolybdenum-tetroxytrioxalate*,  $(\text{NH}_4)_2[\text{Mo}_3\text{O}_4(\text{C}_2\text{O}_4)_3 \cdot 5\text{H}_2\text{O}] \cdot 1.5\text{C}_2\text{H}_5\text{O}$ , were thus prepd., but attempts to prep. the Na and Ba salts similarly resulted in mixts. contg. the required salt with the free metallic oxalate. With the exception of the  $\text{NH}_4$  compd., which pptd. in the form of purplish red crystals contg. both  $\text{H}_2\text{O}$  and  $\text{C}_2\text{H}_5\text{OH}$  of crystn., all the salts described are bluish pink amorphous solids. All are very sol. in  $\text{H}_2\text{O}$ , giving red solns., but insol. in  $\text{C}_2\text{H}_5\text{OH}$  or acetone. Addn. of alkali or  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  to aq. solns. gives a blue coloration, but addn. of any acid restores the red color. The oxalate ion is not detected in aq. soln. by the usual ionic reactions, nor is molybdenum hydroxide pptd. immediately by the addn. of alkali in the cold. Hot KOH gives an immediate ppt. of black flocculent hydroxide, whereas with NaOH a light green form may be obtained. The solns. have marked reducing properties, reducing  $\text{AgNO}_3$  to Ag on boiling.  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  gives a voluminous bluish pink ppt., changing to brown on warming. The hydrolysis of  $\text{MoO}(\text{C}_2\text{O}_4) \cdot x\text{H}_2\text{O}$  also was studied. Conc. of Solution A with subsequent addn. of acetone gave a purple product,  $\text{Mo}_5\text{O}_6(\text{C}_2\text{O}_4)_4$ , contg. both acetone and  $\text{H}_2\text{O}$ . The reactions probably occurring are symbolized as follows: (a)  $5\text{MoO}(\text{C}_2\text{O}_4) + \text{H}_2\text{O} \rightleftharpoons \text{Mo}_5\text{O}_6(\text{C}_2\text{O}_4)_4 + \text{H}_2\text{C}_2\text{O}_4$ ; (b)  $\text{Mo}_5\text{O}_6(\text{C}_2\text{O}_4)_4 \rightleftharpoons \text{Mo}_4\text{O}_5(\text{C}_2\text{O}_4)_3 + \text{MoO}(\text{C}_2\text{O}_4)$ , or  $4\text{Mo}_5\text{O}_6(\text{C}_2\text{O}_4)_4 + \text{H}_2\text{O} \rightleftharpoons 5\text{Mo}_4\text{O}_5(\text{C}_2\text{O}_4)_3 + \text{H}_2\text{C}_2\text{O}_4$ . *Pentamolybdenum hexaoxytetroxalate*,  $\text{Mo}_5\text{O}_6(\text{C}_2\text{O}_4)_4$ , was obtained as a purplish brown cryst. solid, readily sol. in  $\text{H}_2\text{O}$  forming a red soln., but insol. in acetone or alc. *Tetramolybdenum pentoxytrioxalate*,  $\text{Mo}_4\text{O}_5(\text{C}_2\text{O}_4)_3$ , a brown compd., was obtained from the above compd. and also by atm. oxidation of a suspension of the insol.  $\text{Mo}_4\text{O}_5(\text{C}_2\text{O}_4)_3 \cdot 12\text{H}_2\text{O}$  in aq. or  $\text{H}_2\text{C}_2\text{O}_4$  soln. Either of these compds. can be converted into molybdenyl oxalate by treatment with appropriate concn. of  $\text{H}_2\text{C}_2\text{O}_4$ .

RUBY K. WORNER

Gmelins Handbuch der anorganischen Chemie. System No. 59. Eisen. Vol. A, Part 1. 5th ed. Edited by THE GERMAN CHEMICAL SOCIETY. Berlin: Verlag Chemie G m b H. 224 pp. M. 33.

RIESENFELD, E. H., AND KLEMENT, R: *Anorganisch-chemisches Praktikum. Qualitative Analyse und anorganische Präparate*. Leipzig: S. Hirzel. 371 pp. M. 8. Reviewed in *Chimie & industrie* 21, 1345(1929).

## 7—ANALYTICAL CHEMISTRY

W. T. HALL

**Assaying and sampling.** H. W. DANNATT. *Mining J.* (London) **Special Equipment**, No. 53(July 13, 1929).—There has been no marked change in assaying practice during the past decade. The increased use of mech. and elec. appliances is naturally reflected in the lab. in mech. grinders, samplers, "chainomatic" and similar balances, greater use of elec. heat, etc.

ALDEN H. EMERY

**Aminosulfonic acid as primary standard in volumetric analysis.** K. MISUCH. *Farm. Zhur.* 1928, 310-13.—Aminosulfonic acid,  $\text{NH}_2\text{SO}_3\text{OH}$ , and HCl give identical results when titrated with NaOH,  $\text{Na}_2\text{CO}_3$  or Na borate.

B. C. A.

**Reduction bead test as a simple preliminary test.** H. BRINTZINGER. *Z. anal. Chem.* 76, 149-50(1929).—The substance is mixed with about three times its wt. of a reducing flux, such as 2 parts of  $\text{Na}_2\text{C}_2\text{O}_4$ , 2 parts of  $\text{K}_2\text{C}_2\text{O}_4$  and 1-1.5 parts of borax and heated on magnesia in the reducing flame. Characteristic metallic beads are produced in many cases.

B. C. A.

**The benzidine reaction in the analysis of minerals.** M. DOMINIKIEWICZ. *Przemysl. Chem.* 13, 233-6(1929).—The benzidine reaction has been applied to microchem. work for distinguishing between rhodochrosite and siderite as well as for the recognition of ferric and manganic calcites and dolomites, and of cerussite. Small crystals of the mineral with 10% aq. NaOH and a drop of Br are heated on a watch glass on a steam bath for 10-15 min. After the mineral is rinsed off with water it is similarly treated for another 5 min. but this time without Br, and thoroughly washed with water to remove all Br. When a soln. of benzidine is poured over the crystals siderite produces no color

at all while rhodochrosite colors up brightly. This difference in behavior is explained by the relative instability of  $\text{Mn}(\text{OH})_2$  which is formed during the attack by  $\text{NaOH}$ , and which liberates active O. The characteristic coloration is not produced by  $\text{H}_2\text{O}_2$  or  $\text{O}_2$ . Positive reaction is obtained with pyrolusite, manganite, hausmannite and ilmenite. Limonites, hematites, natural magnetites free from Mn, chromite and cassiterite do not react.

**New colorimetric method for estimating copper in Babbitt metal.** N. V. MANDRIKA, *Zhur. Prikladnoi Khim.* 2, 317-9(1929).—Heat 0.5-1 g. of Babbitt metal with 15-25 cc. of concd.  $\text{H}_2\text{SO}_4$ . Cool, dil. carefully with water and add 50-150 cc. of concd.  $\text{HCl}$  until the ppt. redissolves. Dil. to exactly 250 cc. Take 25 cc. of this soln. contg. 5-15 cc.  $\text{HCl}$ , add 25-15 cc. of concd.  $\text{HCl}$  (total amt. of  $\text{HCl}$  must be 30 cc.) and dil with water to exactly 50 cc. Compare this soln. in a colorimeter with a standard soln. prepd. as follows: Dissolve 0.5 g. of pure Cu in 15 cc.  $\text{HNO}_3$  (d. 1.2). Apply heat. Cool, add 5 cc. concd.  $\text{H}_2\text{SO}_4$  and evap. to fumes. Cool, and dil. to 500 cc. To 62.5 cc. of this soln. add 120 cc. concd.  $\text{HCl}$  (d. 1.19) and dil. to 200 cc. with water.

**Microchemical separation of barium and calcium.** R. STREIBINGER, *Mikrochemie* 7, 100-5(1929).—The microchem. detn. of Ba by pptn. with  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  in  $\text{NH}_4$  acetate soln. followed by collection of the ppt. in a filter tube and weighing after drying at  $140^\circ$  yields slightly high results, but good results are obtained if the ppt. is dissolved in dil.  $\text{HNO}_3$ , the chromic acid reduced with alc. and the Ba pptd. with  $(\text{NH}_4)_2\text{SO}_4$ . Ca is detd. in the filtrate from the  $\text{BaCrO}_4$  by pptn. with  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  and weighing as  $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$  after drying at  $110^\circ$ .

**The precipitation of calcium oxalate in the presence of iron, aluminum, titanium, manganese, magnesium and phosphates, with special reference to the determination of total calcium.** H. D. CHAPMAN, *Soil Sci.* 26, 479-86(1928).—Data are given showing the degree to which Ca is pptd. as oxalate in solns. of different  $p_{\text{H}}$  values together with other ions. A method is described whereby it is possible to ppt.  $\text{CaC}_2\text{O}_4$  completely and alone at  $p_{\text{H}}$  4.0 in the presence of Fe, Al, Ti, Mn, Mg and  $\text{PO}_4$  ions. This method is applicable to the detn. of total Ca in soils, soil exts., plant tissue and other cases where the proportion of the various elements is somewhat similar to those used in the exptl. work recorded.

**Microchemical mineral analysis. [Detection of nickel, cobalt, copper, zinc and cadmium.]** A. MARTINI, *Mikrochem.* 7, 30-2(1929).—Addn. of  $\text{NH}_4\text{CNS}$  and pyridine to a neutral Co soln. produces a rose-colored ppt. which becomes sky-blue and cryst. on addn. of  $\text{HNO}_3$ . An ammoniacal Cu soln. to which  $\text{NH}_4\text{CNS}$  has been added yields with pyridine green crystals of the compd.  $3(\text{C}_6\text{H}_5\text{N} \cdot \text{HCNS}) \cdot \text{Cu}(\text{NH}_3)_4(\text{CNS})_2$  and with quinoline sulfate green monoclinic crystals of the compd.  $3(\text{C}_6\text{H}_5\text{N} \cdot \text{HCNS}) \cdot \text{Cu}(\text{NH}_3)_4(\text{CNS})_2$ .  $\text{ZnSO}_4$  yields with a dil. acid soln. of aniline-HCl colorless triclinic crystals of Zn aniline chloride,  $\text{C}_6\text{H}_5\text{NH}_2 \cdot \text{HCl} \cdot \text{ZnCl}_2$ . Ammoniacal solns. of Cu, Ni and Cd salts yield with  $\text{NH}_4\text{CNS}$  and aniline characteristic cryst. compds. of the type  $2(\text{C}_6\text{H}_5\text{NH}_2 \cdot \text{HCNS}) \cdot \text{M}(\text{NH}_3)_4(\text{CNS})_2$ ; the Cu compd. seps. in green, triclinic rosetts, the Ni compd. in pale green, highly refracting, triclinic prisms and the Cd compd. in monoclinic colorless prisms. Co solns. give a rose-colored cryst. ppt. with  $\text{NH}_4\text{CNS}$  and aniline.

**Determination of manganese and iron by successive titration with the permanganate solution.** I. S. TELETOV and N. N. ANDRONNIKOVA, *Zhur. Prikladnoi Khim.* 2, 289-92(1929).—The soln. contg.  $\text{Fe}^{+++}$  and  $\text{Mn}^{++}$  is treated with  $\text{NaOH}$  (12% soln.) and  $\text{H}_2\text{O}_2$  (30% soln.). The ppt. is washed with water and heated in the presence of a known amt. of 0.1 N oxalic acid soln. and  $\text{H}_2\text{SO}_4$ . Mn is detd. by titrating the remaining oxalic acid with N  $\text{KMnO}_4$ . The soln. is then filtered through electrically reduced Cd in order to reduce  $\text{Fe}^{+++}$  to  $\text{Fe}^{++}$ . The resulting soln. is again titrated with  $\text{KMnO}_4$  soln. for  $\text{Fe}^{++}$ .

**Estimation of nickel in steels.** C. L. THOMAS, *J. Elisha Mitchell Sci. Soc.* 43, 214-6(1928).—If the steel is not highly alloyed and does not contain more than 1% Ni, satisfactory results can be obtained by treating the fully oxidized soln. with an excess of  $\text{NH}_4\text{OH}$ , filtering and pptg. Ni in the filtrate with a 3% soln. of dimethylglyoxime in acetone.

**Analysis of steel for manganous oxide.** U. S. DEPARTMENT OF COMMERCE, *Metals and Alloys* 1, 17(1929).—The Dickenson method is not applicable because the  $\text{MnO}$  of slag inclusions is dissolved in the acid with the steel. Expts. have shown that electrolysis may be substituted for the acid soln. In the method in its present age of development the sample is used as the anode in an electrolyte of  $\text{FeSO}_4$ . The Fe is plated out on the cathode and the inclusions fall to the bottom as a slime. The Fe must plate

out in a solid adhering layer to avoid contamination of the residue by metallic Fe. Oxidation of  $\text{Fe}^{++}$  in soln. must be prevented.

**The use of steam in Kjeldahl nitrogen determinations.** F. T. ADRIANO. *Philippine Agr.* 17, 509–10 (1929).—The advantages of steam distn. instead of direct heating to carry over  $\text{NH}_3$  from the digested sample are pointed out and a successful installation for accomplishing it is illustrated.

**The determination of nitrate nitrogen by alkaline reduction with aluminum powder.** A. SEYEWETZ. *Bull. soc. chim.* [4], 45, 463–5 (1929).—Nitrates, nitrites, sulfonitrates and nitrated cotton can be analyzed for nitrate N content by reduction to  $\text{NH}_3$  in alk. soln. with impalpable Al powder (which is gray and not to be confused with bright Al powder used in varnishes, etc.) and absorption of  $\text{NH}_3$  in standard  $\text{H}_2\text{SO}_4$  soln.

**Tests for hydrogen peroxide solution.** P. A. BERRY. *Australasian J. Pharm.* 9, 62 (1928); *Quart. J. Pharm.* 1, 268; cf. *C. A.* 22, 2808, 3371.—The gasometric method of estn. of the B. P. is inaccurate and the necessary corrections for temp. and pressure ... tedious to carry out. The  $\text{KMnO}_4$  method is quick and accurate, but certain of the preservatives used affect the result. The iodometric method, when carried out as described below, is accurate, and neither preservatives nor variations in temp. interfere. This method is recommended for inclusion in the pharmacopeia. Twenty cc. of the soln. of  $\text{H}_2\text{O}_2$  is dild. with distd. water to 200 cc. Twenty cc. of the dild. soln. is placed in a 750-cc. flask and 20 cc. of dil.  $\text{H}_2\text{SO}_4$  acid (1 to 9 by vol.) added. About 2 g. of solid KI is added, shaken until dissolved, the mouth of the flask covered with a watch glass and the mixt. allowed to stand for 15 min. It is then titrated with 0.1 N  $\text{Na}_2\text{S}_2\text{O}_3$  sol. starch soln. and water to make 200 cc. being added toward the end. One cc. of 0.1 N  $\text{Na}_2\text{S}_2\text{O}_3$  is equiv. to 0.0017 g. of  $\text{H}_2\text{O}_2$ . This soln. is standardized under similar conditions by treating 25 cc. of 0.1 N  $\text{K}_2\text{Cr}_2\text{O}_7$  soln. with the same quantities of  $\text{H}_2\text{SO}_4$  and KI. Phenolphthalein should be used instead of methyl orange for estimating the acidity. The B. P. limit of residue is too high and 0.25 per cent is recommended. The U. S. P. test for preservatives should be included in the B. P. while the standard of strength should be 28 to 3.2% wt. in vol.

**Qualitative microanalysis. III. Detection of thiocyanate, fluoride and copper, two methods of distinguishing between tap water and distilled water, detection of alkali in water, and a drop reaction for ammonia.** F. FEIGL [WITH G. HIRSCH AND I. TAMCHYNA]. *Mikrochemie* 7, 10–20 (1929); cf. *C. A.* 19, 1108.—Addn. of thiocyanate to a 0.1 N-I soln. contg. 1.3 g./100 cc. of Na azide catalyzes the reaction  $2\text{NaN}_3 + \text{I}_2 = 2\text{NaI} + 3\text{N}_2$  and the soln. becomes decolorized with evolution of N; as little as 0.03 mg. of thiocyanate is readily detected in the presence of most inorg. oxyacids and the common org. acids by this test, but sulfides and thiosulfates interfere and must be previously removed by  $\text{HgCl}_2$ . For the detection of fluoride in insol. substances the substance is treated with a HCl soln. of the violet Zr alizarin compd. (de Boer, *C. A.* 19, 793), which becomes yellow if F is present. Traces of Cu in soln. may be detected by adding a few drops of dilute  $\text{Zn}(\text{NO}_3)_2$  soln. followed by a soln. of 8 g. of  $\text{HgCl}_2$  and 9 g. of  $\text{NH}_4\text{CNS}$  in 100 cc. of water; with 0.00075 mg. of Cu per cc. a violet, cryst. ppt. is obtained. Tap water may be distinguished from distd. water by the reddish violet color it gives on the addn. of a few drops of a blue ammoniacal soln. of 2,3-dihydroxyanthraquinone or by the red, cryst. ppt. it produces with a soln. of the Na salt of 2,4,5,7-tetranitro-1,8-dihydroxyanthraquinone; both these reactions are due to the presence of Ca and Mg in tap water. Addn. of a soln. of the compd.  $\text{Hg}(\text{CN})_2 \cdot \text{AgNO}_3$  to water contg. free alkali produces a turbidity due to the formation of  $\text{AgCN}$ . To detect  $\text{NH}_3$  in a neutral or slightly acid soln. 1 drop of the liquid is mixed with 1 drop of a dil. soln. of *p*-nitro diazobenzene in HCl on a small watch-glass and a small piece of quacklime is dropped into the mixt.; if  $\text{NH}_3$  is present, a red ring appears round the lime.

**The oxidation of mercuric cyanide by sodium hypobromite. Its application to the determination of mercury cyanide and cyanate.** J. GOLSE. *Bull. soc. chim.* 45, 177–83 (1929).—To titrate a  $\text{Hg}(\text{CN})_2$  soln., treat with an excess of  $\text{NaBrO}$  soln., which transforms  $\text{Hg}(\text{CN})_2$  into  $\text{HgO}$  and  $\text{NaCNO}$ . Add KI and  $\text{AcOH}$ , and titrate the I liberated with  $\text{Na}_2\text{S}_2\text{O}_3$ . The  $\text{NaBrO}$  soln. must be standardized immediately before use. To titrate  $\text{Hg}$  after the preceding oxidation, add  $\text{NH}_3$  and boil; to eliminate the excess of  $\text{NaBrO}$ , add an excess of  $\text{NaCN}$  soln. which dissolves the  $\text{HgO}$  ppt., and titrate the excess  $\text{NaCN}$  with  $\text{AgNO}_3$  in the presence of KI and  $\text{NH}_3$ . ALBERT L. HENNE.

**Microchemical determination of hydrocyanic acid by the Brunswik reaction.** V. P. MALITZKII AND M. T. KOSLOVSKII. *Mikrochemie* 7, 94–9 (1929).—The sensitivity of the Brunswik reaction is increased by the use of a  $\text{AgNO}_3$  soln. acidified with

**HNO<sub>3</sub>.** The material to be tested is placed in a small tube together with a few drops of a satd. soln. of oxalic acid and 2-3 drops of KMnO<sub>4</sub> soln. if sulfides are present; the tube is covered with a watch-glass to the bottom of which is attached a small drop of the AgNO<sub>3</sub> soln. colored with methylene blue. If cyanides are present a turbidity due to AgCN appears in a few minutes; under the microscope blue needles are seen. The sensitivity of the test is  $6 \times 10^{-8}$  g. of HCN. B. C. A.

**Detection of sulfurous acid with Bettendorf's reagent.** S. A. DUNAIEV. *Farm. Zhur.* 1928, 379.—If Bettendorf's reagent is covered with a soln. contg. sulfite, reduction to sulfide produces a yellowish brown ring of Sn sulfides; 0.06% of sulfite can be detected. B. C. A.

**The use of organic reagents in the identification of cations.** ARMANDO NOVELLI. *Rev. farm.* (Buenos Aires) [2], 2, 148-58(1929).—The reactions of Al, Ni, Co, Mg and Zn with org. substances are described. A. E. MEYER

**The use of organic reagents in the identification of anions.** ARMANDO NOVELLI. *Rev. farm.* (Buenos Aires) [2], 2, 205-7(1929).—The reactions of Cl, Br and I with org. substances are described. A. E. MEYER

**Carbon determination in organic compounds and in soils by means of permanganic anhydride.** LUIGI U. DENARDO. *Ann. sci. agron.* 46, 9-13(1929).—Carbonaceous substances contained in a small flask are decompd. by the addn. of a mixt. KMnO<sub>4</sub> and H<sub>2</sub>SO<sub>4</sub> and the evolved CO<sub>2</sub> is absorbed in KOH after passing through a purifying train consisting of H<sub>2</sub>SO<sub>4</sub>, asbestos and pumice. The reaction is complete in a few seconds. Pure org. compds. were found to give theoretical results while soil samples gave almost identical values with those obtained by combustion methods. K. S. M.

**Potentiometric determination of reducing sugars.** H. TRYLLER. *Z. Spiritusind.* 52, 27-8(1929).—The end point in the detn. of reducing sugars by titration against Fehling soln. is ascertained electrometrically by means of Cu electrodes and a galvanometer. As the end point of the reaction is approached the galvanometer deflection approaches zero and is very sensitive to slight change of Cu content, i. e., to 0.1 cc. of sugar soln. A. SCHULTZ

**Microchemical detection of glycerol, ethylene glycol and d-mannitol.** H. ALBER. *Mikrochemie* 7, 21-9(1929).—The sensitivity of the following tests for the detection of glycerol, glycol and mannitol has been detd. and the conditions for carrying them out microchemically have been standardized: Fischer and Tafel's hypobromite method and its various modifications (*Ber.* 20, 3384-90), Gläser and Moravski's formic acid method (*Monatsh.* 10, 578-84), and Rose's boric acid method (*Diss.*, Erlangen, 1902). B. C. A.

**Determination of phenols and alcohols.** ALBERT VERLEY. *Am. Perfumer* 24, 233-4(1929).—By means of a pipet remove 10 cc. of the acetylation mixt. (2 pts. C<sub>2</sub>H<sub>5</sub>N, 1 pt. Ac<sub>2</sub>O contg. 5% AcCl) to a suitable flask, dil. with H<sub>2</sub>O and make neutral to phenolphthalein with N NaOH. Into a perfectly dry, round-bottomed flask introduce about 2 to 3 g. (0.01 mole) of the sample accurately weighed in a small glass tube about 4 cm. in length, closed at one end, so that it can be introduced easily into the flask. Now add 10 cc. of the acetylating mixt., close the flask with a rubber stopper provided with a reflux condenser, then place on a water bath for a time which varies according to the alc. and nature of the alc. group. After cooling, rinse the inside of the tube, the outer surface of the stopper and neck of the flask carefully with distd. H<sub>2</sub>O, and est. the excess acid by means of N NaOH soln. Although the end point in the titration of the acetylating mixt. alone with NaOH is distinct, it is much less so after contact with the alc. to be acetylated. Then it is necessary to use considerable indicator, possibly 10 to 15 drops. In general, 1-2 hrs. heating suffices for primary, and 2-3 hrs. for secondary alcs. The error due to weighing is negligible if a balance sensitive to 1/10 mg. is available, but the probable error arising from the removal of 10 cc. of the acetylating mixt. is on the contrary far from negligible. Actually, 10 cc. of the mixt. corresponds to 83 cc. of N NaOH soln. If an error of only 0.05 cc. is made in the withdrawal, this involves an error of 0.42 cc. N NaOH, which would give an error of 3.27% in the titration of menthol (2-g sample). It is thus necessary in order to obtain strictly accurate results to work always at the same temp. and with the same pipet, which should have an upper limb very finely calibrated. The estn. of an alc. can prove exact in the absence of other substances liable to acetylation. Consequently, this method is ill-advised when the mixt. contains a tertiary alc., a phenol, a primary or secondary amine, or an aldehyde. However, the presence of an aldehyde in small amts. in an essential oil will not affect the accuracy of the estn. Inaccurate results may also be expected with any alc. below the pentanol. Otherwise the method should yield results with accuracy approaching 1 in 500. W. O. E.

**A volumetric process for the estimation of phenazone.** J. RAE. *Pharm. J.* **121**, 575(1928).—Phenazone (A) forms with picric acid (B) a compd. insol. in excess of B. Prep. a 0.1 N soln. of B in 90% EtOH (23 g. in 1000 cc.) and standardize it against 0.1 N NaOH (phenolphthalein). 1 cc. of soln. of B = 0.0188 g. A. To det. the purity of a sample of A, dissolve 1 g. of A in 100 cc. H<sub>2</sub>O; to 10 cc. of this soln. add 25 cc. 0.1 N soln. of B and H<sub>2</sub>O to make 100 cc. Allow to stand for 10 min., shaking occasionally, and filter. In 50 cc. of the filtrate det. excess of B by titration with 0.1 N NaOH. With samples of known strength, av. recovery was -2.09% (0.6-3.92%). Similar work by Borloz (*C. A.* **21**, 3582) was overlooked.

S. WALDBOTT

**The estimation of diphenylamine and diphenylnitrosamine in the presence of their derivatives.** H. RYAN, J. KEANE AND J. DUNNE. *Sci. Proc. Roy. Dublin Soc.* [N. S.], **19**, 85-100(1928).—Ext. nitrocellulose powder with alc. and reduce the extractive with SnCl<sub>2</sub> and HCl. Pass a current of steam through the reduced mixt., which a definite amt. of diphenylamine distills. Ext. with CHCl<sub>3</sub> and det. diphenylamine volumetrically by Br in CHCl<sub>3</sub>. Adsorption of Br was greater than the theoretical quantity, when mixts. of 2 nitro derivs. of diphenylamine were examd., especially when one was diphenylnitrosamine.

**Tablets for titration of alkaline substances.** JOHN H. BUCHANAN (to American Bottlers of Carbonated Beverages). U. S. 1,721,809, July 23. Standard tablets are formed contg. KHSO<sub>4</sub> with an indicator such as tetrabromophenolsulfonephthalein.

## 8- MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

**New occurrences of germanium.** I. JACOB PAPISH. *Econ. Geol.* **23**, 660-70 (1928).—P. examd. samples of stannite, pyrrargyrite, native Cu and calamine from different localities in an arc spectrograph, the method being described, and found Ge in some samples of all these minerals. The Ge content of a sample of pyrrargyrite from Colquechaca, Bolivia was estd. to be over 1%, while samples from several other localities showed none. An outline of the known occurrences of Ge in minerals is given.

ELLIOTT J. ROBERTS

**Electrical conductivity and polished mineral surfaces.** ROGER D. HARVEY. *Econ. Geol.* **23**, 778-803(1928).—Using 2 methods, H. has measured the approx. elec. resistivity of a large suite of minerals in polished section. One method used was the Wheatstone bridge method, making contact with the polished surface through Pt-Ir needles set 0.085 mm. apart. The other method involved the use of 4 needles in line, the outer two, of Cu, 0.41 mm. apart, being in series with a source of direct current and an ammeter; the inner two, of Pt-Ir, 0.17 mm. apart, were connected to a potentiometer and galvanometer, with which the potential drop through the 0.17 mm. of mineral was measured. Contact resistance is eliminated in this latter method, but fluctuations of 400% in the readings still occur, due to variations in orientation and size of the grains.

ELLIOTT J. ROBERTS

**Variation of the axial ratio, interfacial angle and volume of calcite due to heating and its dissociation phenomena.** SHUKUSUKU KÔZU, HOICHI MASUDA AND JUN'ICHI

URDA. *Tohoku Imp. Univ., J. Petrol., Mineral. and Ore Deposits (Japan)* 1, 1-12 (1929).—A pyramidal calcite crystal from Cumberland, England, was measured as to thermal expansion along axis  $a$ , and one from Ashio along axis  $c$ . The highest temp. at which this has been measured previously was 598°; K., M. and U. measured it at the temp. range of 25 to 1000° with a differential dilatometer, finding that on heating calcite expands along  $c$  and contracts along  $a$ . At 20–700°, the expansion along  $c$  is given by  $l_1 = 0.0023221 t + 0.0000013648 t^2$ , the contraction along  $a$  by  $l_2 = 0.000739 t + 0.0000002932 t^2$ . The curve bends slightly upwards above 700° and rapidly above 800°. Along  $c$ , calcite expands by 2.21% of the amt. of expansion at 20°, while along  $a$  it contracts by 0.37%. Tables and figures showing the calcd. and observed values of expansion and contraction are given. Taking for the axial ratio of calcite the value of Rinne (*C. A.* 18, 1408(1924)),  $a:c = 1:0.8549$ , at 700°,  $a:c = 1:0.8770$ , the interfacial angle  $r \wedge r' = 74^\circ 56' 47''$  at 20° and  $76^\circ 4' 39''$  at 700°. Tables showing the angles at various temps. are also given. The vol. change and the change of  $d$  with temp. have also been calcd., showing that the vol. expansion amounts to 1.46% of the value at 700°. In the  $d$ . calcn. the value  $d_{700} = 2.7102$  was adopted as the standard, giving  $d_{700} = 2.671$ . The  $d$ . values at different temps. are shown by tables. The rapid change of thermal expansion at 700–800° is due to the decompn. of calcite into  $\text{CaO} + \text{CO}_2$ . The measurement of the dissocn. temp. was carried out by heating powd. calcite in air under 1 atm., the result showing that the dissocn. occurs at 700–930°. For measuring the true dissocn. temp. the expt. must be carried out in an atm. of  $\text{CO}_2$ . K. SOMEYA

**The meteoric stone of Hinojo, province of Buenos Aires.** ENRIQUE H. DUCLOUX *Rev. facultad cienc. quim.* (Univ. La Plata) 5, Pt. 2, 1-7(1929).—The dark heterogeneous mass,  $d$  3.407–3.411, weighed 1155 g. Sepns. on 3 samples with a magnet gave magnetic fractions of 30.46, 17.86 and 19.77%, resp. The chem. analyses were: magnetic fraction, insol. residue 41.525,  $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$  23.885,  $\text{CaO}$  0.266,  $\text{MgO}$  9.000,  $\text{NiO}$  1.89,  $\text{Fe}$  21.482,  $\text{Ni}$  0.908,  $\text{Co}$  0.046,  $\text{S}$  1.766–1.853,  $\text{P}$  0.104,  $\text{Cr}$ ,  $\text{Mn}$  traces; stony fraction,  $\text{SiO}_2$  37.320,  $\text{Al}_2\text{O}_3$  2.410 2.425,  $\text{FeO}$  13.360,  $\text{Fe}_2\text{O}_3$  17.975,  $\text{MnO}$  0.652,  $\text{Cr}_2\text{O}_3$  trace,  $\text{NiO}$  1.516–1.614,  $\text{CoO}$  0.046,  $\text{CaO}$  2.475,  $\text{MgO}$  21.787,  $\text{K}_2\text{O}$  0.207,  $\text{Na}_2\text{O}$  1.653,  $\text{P}_2\text{O}_5$  0.480,  $\text{H}_2\text{O}$  and loss 0.119; total compn. calcd. from analyses of fractions,  $\text{SiO}_2$  34.33,  $\text{Al}_2\text{O}_3$  2.22,  $\text{FeO}$  12.29,  $\text{Fe}_2\text{O}_3$  16.53,  $\text{MnO}$  0.59,  $\text{Cr}_2\text{O}_3$  trace,  $\text{NiO}$  1.39,  $\text{CoO}$  0.04,  $\text{CaO}$  2.27,  $\text{K}_2\text{O}$  0.19,  $\text{Na}_2\text{O}$  1.52,  $\text{P}_2\text{O}_5$  0.44,  $\text{Fe}$  6.61,  $\text{Ni}$  0.27,  $\text{Co}$  0.01,  $\text{S}$  0.54,  $\text{P}$  0.03,  $\text{H}_2\text{O}$  and loss 0.69%. The mineralogical compn. is also calcd. W. L. HULL

**Remarks on the meteorite, El Mocovi.** ENRIQUE H. DUCLOUX *Rev. facultad cienc. quim.* (Univ. La Plata) 5, Pt. 2, 9-12(1929).—The meteorite,  $d$  7.632–7.710, wt. 732 kg., was found in Los Guanacos. D. analyzed 4 samples of drillings, a representative being: siliceous material 0.210,  $\text{Fe}$  93.135,  $\text{Ni}$  5.680,  $\text{Co}$  0.304,  $\text{C}$  (graphite) 0.239,  $\text{S}$  0.141,  $\text{P}$  0.166,  $\text{Cr}$  trace,  $\text{Mn}$  0.010, ( $\text{Ir}$ ,  $\text{Ru}$ ,  $\text{Os}$ ) 0.035–0.087. The probable minerals present were:  $\text{Fe}_{14}\text{Ni}$  77.178,  $\text{Fe}_7\text{S}_8$  0.357,  $(\text{Fe}, \text{Ni}, \text{Co})_3\text{P}$  1.080,  $\text{Cr}_2\text{O}_3$  trace,  $\text{Fe}$  20.810,  $\text{C}$  0.239. W. L. HULL

**Data on the meteoric stone of Cachari.** ENRIQUE H. DUCLOUX. *Rev. facultad cienc. quim.* (Univ. La Plata) 5, Pt. 2, 13-23(1929).—This meteorite, wt. 21 kg.,  $d$  3.13, was found in the province of Buenos Aires. Of a sample from the predominating gray zone 39.09% was sol. in  $\text{HCl}$ . Analyses of the sol. and insol. portions, resp., were:  $\text{SiO}_2$  17.705, 30.970,  $\text{Al}_2\text{O}_3$  12.650, 1.960,  $\text{Fe}_2\text{O}_3$  traces,  $\text{FeO}$  1.440, 18.486,  $\text{MnO}$  0.321, 0.420,  $\text{Cr}_2\text{O}_3$  none, 0.065,  $\text{NiO}$  trace, none,  $\text{CoO}$  none,  $\text{TiO}_2$  trace, 0.078,  $\text{CaO}$  5.802, 3.102,  $\text{MgO}$  1.131, 5.680,  $\text{P}_2\text{O}_5$  0.055, none. The former contained also  $\text{CO}$ , 0.060,  $\text{S}$  trace, and the latter  $\text{K}_2\text{O}$  0.132,  $\text{Na}_2\text{O}$  0.903%. Total compn. from the av. results of analyses of gray and dark parts were: loss at red heat 0.196,  $\text{SiO}_2$  48.475,  $\text{Al}_2\text{O}_3$  13.945,  $\text{Fe}_2\text{O}_3$  0.237,  $\text{FeO}$  19.803,  $\text{MnO}$  0.783,  $\text{Cr}_2\text{O}_3$  0.062,  $\text{CoO}$  none,  $\text{TiO}_2$  0.072,  $\text{CaO}$  8.617,  $\text{MgO}$  6.840,  $\text{K}_2\text{O}$  0.127,  $\text{Na}_2\text{O}$  0.919,  $\text{P}_2\text{O}_5$  0.058,  $\text{SO}_3$  0.056%,  $\text{NiO}$ ,  $\text{S}$  traces. The total compn. is compared with that of all known meteorites of the type to which it belongs. W. L. HULL

**The meteorite of Renca, province of San Luis.** ENRIQUE H. DUCLOUX AND FRANCO PASTORE. *Rev. facultad cienc. quim.* (Univ. La Plata) 5, Pt. 2, 111-20(1929).—Analyses of the meteorite, probable wt. 300 g.,  $d$  3.410–3.411, were: magnetic fraction 9.06,  $\text{Fe}$  86.535,  $\text{Ni}$  8.741,  $\text{Co}$  0.528,  $\text{S}$  2.160,  $\text{P}$  0.088,  $\text{Cr}_2\text{O}_3$ ,  $\text{FeO}$  1.672%,  $\text{TiO}_2$  trace, stony part 90.94,  $\text{SiO}_2$  42.190,  $\text{Al}_2\text{O}_3$  3.330,  $\text{FeO}$  22.860,  $\text{MnO}$  0.855,  $\text{Cr}_2\text{O}_3$  0.510,  $\text{CaO}$  1.584,  $\text{MgO}$  21.779–22.030,  $\text{NiO}$  1.240,  $\text{K}_2\text{O}$  0.634–0.684,  $\text{Na}_2\text{O}$  2.602,  $\text{SO}_3$  0.068,  $\text{S}$  2.844%,  $\text{Fe}_2\text{O}_3$ ,  $\text{TiO}_2$ ,  $\text{CoO}$  traces; total compn.,  $\text{SiO}_2$  38.392,  $\text{Al}_2\text{O}_3$  3.030,  $\text{FeO}$  20.802,  $\text{MnO}$  0.778,  $\text{Cr}_2\text{O}_3$  0.464,  $\text{CaO}$  1.441,  $\text{MgO}$  20.047,  $\text{NiO}$  1.128,  $\text{K}_2\text{O}$  0.577,  $\text{Na}_2\text{O}$  2.367,  $\text{SO}_3$  0.062,  $\text{S}$  2.588,  $\text{Fe}$  7.788,  $\text{Co}$  0.787,  $\text{P}$  0.008%,  $\text{Fe}_2\text{O}_3$ ,  $\text{TiO}_2$ ,  $\text{CoO}$ ,  $\text{P}_2\text{O}_5$  traces. Under the microscope magnetic pyrite, olivine and orthorhombic pyroxene were recog-

nized. The compn. is compared with that of the meteorites, La Colina (*C. A.* 21, 369) and Santa Isabel (*C. A.* 19, 2318). W. L. HILL

**Report of the committee on processes of ore deposition.** W. LINDGREN. *Econ. Geol.* 23, 591-611(1928); cf. *C. A.* 22, 3604.—L. surveys the field and divides the problems into 5 classes, 2 of which are: mineralogical and chem. features, and physico-chem. investigations of the processes of ore deposition. In order to make significant advances in this field there must be coöperation among geologists, as well as between geologists on one hand and chemists and physicists on the other hand. E. J. R.

**The time sequence of hypogene ore mineral deposition.** W. H. NEWHOUSE. *Econ. Geol.* 23, 647-59(1928).—N. finds, by an examn. of the literature, that the order of introduction of the metals is approx. that of increasing at. wt. except for Sn, W, Bi and Mo. The same holds for the acidic elements. The minerals which are deposited first have a higher heat of formation than the later ones. The simple sulfides except for Bi are introduced in the order of decreasing soly. N. explains this on the basis that during the crystn. of the parent magma, the more sol. sulfides were given off first and the less sol. later when more H<sub>2</sub>O had been liberated by the crystn. processes.

ELLIOTT J. ROBERTS

**Dolomitization and ore deposition.** D. F. HEWETT. *Econ. Geol.* 23, 821-63 (1928).—Dolomitization of limestone wall rocks is most commonly found near Zn and Pb deposits, but in a few places it is near Cu deposits. Rock alteration preceded the deposition of metal sulfides. It is doubtful whether the Mg was derived from similar sources in the different districts. Dolomitization may sometimes be used as a local aid in searching for ore bodies.

ELLIOTT J. ROBERTS

**Certain magmatic titaniferous iron ores and their origin.** F. F. OSBORNE. *Econ. Geol.* 23, 724-61, 895-922(1928).—Certain titaniferous Fe ores in anorthosites, gabbros and related rocks are magmatic injections—not magmatic segregations nor of hydrothermal origin. Their temp. of solidification was between 800° and 1100°. Filter pressing is the explanation advanced to account for the ore bodies in the anorthosite. Lamellas of ilmenite and spinel in magnetite, and of hematite in ilmenite, are due to the unmixing of solid solns. which were stable at the temp. of formation. A content of FeO in the residual magma greater than that necessary to form ilmenite and ortho- or metasilicates gives rise to magnetite with the ilmenite. Otherwise hematite is formed with the ilmenite. Evidence is adduced for the solid soly. of magnetite in hematite.

ELLIOTT J. ROBERTS

**Geologic structure of the Cuyuna iron district, Minnesota.** CARL ZAPFFE. *Econ. Geol.* 23, 612-46(1928).—Z. finds 2 major bands of ore in the north part of this district. In both, the lower horizon is manganiferous; but the lower of the two major bands is predominantly the more so.

ELLIOTT J. ROBERTS

**The ancient mining works of Cassandra, Greece.** CORNELIO L. SAGUI. *Econ. Geol.* 23, 671-80(1928).—The deposits contain Au, Ag, Pb, Zn and some Cu. The minerals include pyrite, galena, zinc blende, arsenopyrite, lollingite, quartz, calcite, rhodochrosite and rhodonite, of which the last 2 have been altered to pyrolusite near the surface. Some of the mines must have been worked for 25 centuries before 300 B. C.

ELLIOTT J. ROBERTS

**Copper veins on Susie Island, Lake Superior.** G. M. SCHWARTZ. *Econ. Geol.* 23, 762-72(1928).—Bornite, chalcocite, chalcopyrite, pyrite, covellite and malachite occur in a calcite-quartz-barite gang. The ore assayed 0.16 oz. Ag per ton and showed no As. A pronounced zoning of the calcite occurs, due to minute inclusions of chalcocite. Pyrite has been replaced by chalcocite and more rarely by bornite or chalcopyrite. Chalcopyrite is often replaced by bornite and *vice versa*; chalcocite is replaced by bornite. The sulfides occur in peculiar concentric, roset and scallop-like structures in the calcite.

ELLIOTT J. ROBERTS

**Notes on the nickel and copper deposits in the norite complex west of the Pilansberg district, Rustenberg, Transvaal.** J. A. L. ORTLEPP. *J. Chem. Met. Mining Soc., S. Africa* 29, 233-6(1929).—In a discussion of Schoch's paper (*C. A.* 23, 2910), O. gives certain results of assays and concn. tests on similar ore. ALDEN H. EMERY

**The upland diamond deposits of the Diamantina district, Minas Geraes, Brazil.** LESTER S. THOMSON. *Econ. Geol.* 23, 705-23(1928).—There are 2 sources of the diamonds: a breccia which was probably originally a basic igneous intrusion which entrained fragments of the country rock through which it was forced; and 2 series of conglomerates, one of which is older than the breccia. The diamonds and attendant minerals (quartz, rutile, anatase, ilmenite and kyanite) in the breccia are not water worn and therefore primary while those in the conglomerates are water worn and

therefore secondary; and, since one of the conglomerates is older than the breccia, another source for these diamonds must be postulated. A similar double source is necessary in the case of the South African deposits.

ELLIOTT J. ROBERTS

**Some geological consequences of the selective adsorption of water and hydrocarbons by silica and silicates.** P. G. NUTTING. *Econ. Geol.* **23**, 773-7(1928).—Water, adsorbed on silica and silicates as H and OH ions, may be displaced by the stronger (brown or black) alkyl hydrocarbons but not by the weaker lighter ones. Petroleum may enter and fill sands previously filled with water or water solns. provided it contains basic constituents stronger than OH, thus changing the film adsorbed on the silicates from OH to alkyl hydrocarbon, and reversing the character of the silicate from hydrophilic to hydrophobic. The most efficient flotation oils for sulfide ores are those composed of hydrocarbons just a little weaker than OH ions. The thickness of the adsorbed film of strong alkyl hydrocarbons on some pure quartz oils and was detd. to be  $8 \times 10^{-8}$  cm.

ELLIOTT J. ROBERTS

**A contribution to the knowledge of the transformations of fatty acids in the course of geologic periods.** I. G. L. STADNIKOV AND ANNA WEIZMANN. *Brennstoff-Chem.* **10**, 61-3(1929).—According to the Engler theory bituminous minerals and petroleum have resulted by transformation of plant and animal fatty acids through the action of heat and pressure into hydrocarbons. The authors ext. Siberian boghead coal with  $C_6H_6$ ,  $CHCl_3$ , and alc. NaOH and convert the extd. acids into methyl esters. These are sepd. by fractionation and various fatty acids from  $C_8$  to  $C_{22}$  are identified. By similar studies of materials representing various coalification stages they hope to show how chem. transformation therein has progressed under "natural conditions" II. G. L. STADNIKOV AND Z. VOZZHINSKA. *Ibid* 81-2.—A sample of Matagansky boghead coal was extd. and examd. for fatty acids by the method used above. Thirty g of satd. and unsatd. acids of the fatty acid series were recovered. This was approx 5% of the wax sample examined. The presence of lactones and anhydrides was indicated. The amount of material available was too small for positive identification of individual compds. Cf. *C. A.* **23**, 2128.

**Physicochemical factors controlling magmatic differentiation and vein formation.** CLARENCE S. ROSS. *Econ. Geol.* **23**, 864-86(1928).—R. discusses the origin and properties of the water-rich differentiate of a crystallizing igneous mass.

E. J. R

**The origin of corundum aplite.** ALEX L. DU TOIT. *Econ. Geol.* **23**, 806-9(1928).—T., the proponent of the theory that albitites and plumasites were formed by the desilication of pegmatites, replies to Larsen's criticisms of that theory (*C. A.* **23**, 4169), and upholds his previous views (*C. A.* **14**, 514).

ELLIOTT J. ROBERTS

**Origin of white clays and bauxite, and chemical criteria of peneplanation.** W G WOOLNOUGH. *Econ. Geol.* **23**, 887-94(1928); Cf. *C. A.* **23**, 1086.—One essential criterion of a high degree of perfection of peneplanation is that the rocks show evidence of very deep and very complete chem. alteration by meteoric waters. If the residual material consists entirely of the most insol. products of rock weathering, a uniformly moist climate may be postulated during the last stages of peneplanation. If, on the other hand, there is a crust of concretionary, amorphous material, chiefly  $Al_2O_3$ ,  $Fe_2O_3$ , or amorphous  $SiO_2$ , resting upon a substratum of insol. residual constituents, the final stages of peneplanation took place under climatic conditions marked by sharply defined alternations of satn. and desiccation.

ELLIOTT J. ROBERTS

**A study of a fossil resin of the Republic of Argentina.** JUANA CORTELEZZI. *Rev. facultad cien. quim.* (Univ. La Plata) **5**, Pt. 2, 25-63(1929).—In an exhaustive study, including comparative data and illustrative cuts, the following conclusions were reached (1) The material belongs to the lower Tertiary and is cotemporaneous with known beds of amber; (2) its properties approach those of amber and copal; and (3) on account of its peculiar properties it should be considered as a new species. The reddish yellow, transparent or semi-transparent resin, a nodular, amorphous, brittle material possessed conchoidal fracture, was without odor or taste, acquired a —elec. charge and contained remains of plant life. It showed feeble birefringence,  $n_D = 1.529$ , sp. gr. = 1.0527, hardness 2-3, heat of combustion 8540 cal. per g., and on heating modifications were noted at 160°, 220°, 260°, 300° and 335° (b. p.). The chem. analysis was: C 76.550, H 10.202, O 13.188, S (Hempel) 0.059, N negative, ash (K, Fe, Ca, Mg,  $SiO_2$ ,  $SO_3$ ) 0.08,  $H_2O$  at 100° 2.30%; sol. in alc. 49.60, in ether 59.63, in chloroform 98.4, essential oils 5.30, bitter substances 7.22, free acids 1.34; acid number 42.15, saponification number 109.6. Qual. tests indicated the presence of acids, alcohols and resins.

## 9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

**Progress in metallurgy during 1928.** H. C. H. CARPENTER. *Iron Coal Trades Rev.* 118, 142(1929). LESLIE B. BRAGG

**The history of flotation.** CH. BERTHELOT. *Rev. métal.* 26, 364-6(1929).—A brief sketch. A. PAPINEAU-COUTURE

**The concentration of the ores of western Quebec.** J. S. GODARD. Can. Dept. Mines, Mines Branch, *Rept.* No. 695, 164-72(1929), cf. C. A. 23, 1845.—These ores are complex mixts. of sulfides of Cu, Zn and Fe carrying values in precious metals. They may be classified as (I) milling ores, (II) direct smelting ores and (III) concg. ores, and can be further divided as follows: I (a) predominately arsenopyrite with Au in fractures in quartz, (b) predominately pyrite with values of Au; II (a) heavy sulfides of Cu and Fe with Cu above 4% and the Au in the Cu, (b) highly siliceous Cu and Au ores used as flux in Cu converters; III (a) disseminated chalcopyrite-rhyolite ore bodies not used as flux, (b) disseminated pyrite with Au (distinguished from I (b) only by proximity to the smelter), (c) disseminated ZnS with pyrite (d) disseminated ore contg. small amts of chalcopyrite, sphalerite, and pyrite whose chief value is Au, (e) heavy sulfides of Cu and Fe with pyrrhotite predominating—too low in Cu and Au to belong to II (a), (f) heavy-sulfide ores predominately pyrite and low in Cu, Zn and because of unfavorable ratio of Cu to Zn, oxidized condition of ore and the assocn. of precious metals, (g) heavy-sulfide and disseminated-sulfide ores of Cu, Zn and Fe, pyrrhotite predominating and contg. some values in Au and Ag, difficult to conc. because of unfavorable ratio of Cu to Zn, oxidized condition of ore and the assocn. of precious metal values. Examples of each are given and concn. tests on 7 samples described. ALDEN H. EMERY

**Studies on the roasting of zinc blende.** FRANZ KLEIN *Metall u. Erz* 26, 217-25 (1929).—The work is confined to the consideration of the influence exerted by the phys. nature of the ZnS, the temp., and the compn. of the roasting gas during the several stages of the roasting process. One sample of ZnS was chemically pptd. contg. 64.8% Zn, 34.6% S, 0.4% Fe and 0.05% Pb. Another sample was cryst. ZnS contg. 64.4% Zn, 34.6% S, 0.3% Fe and a trace of Pb. Roasting was done in a horizontal elec. tube furnace in which the amt and nature of air could be controlled. Roasting of pptd ZnS began at 345°, and that of cryst. ZnS at 350°. The progress of the roasting process is influenced by the size of the particles. In the temp. interval 470-550° ZnS ignites. At about 700° an endothermic reaction occurs, the ZnSO<sub>4</sub> decomposes into ZnO + SO<sub>3</sub>. Roasting velocity is greater for pptd. ZnS than for cryst. ZnS. The amt. of ZnSO<sub>4</sub> formed is dependent on the gas compn. The % ZnSO<sub>4</sub> is greater the more favorable the condition for the formation of SO<sub>3</sub> from SO<sub>2</sub> and O<sub>2</sub>. C. H. LORIG

**The hydrometallurgical treatment of high-grade iron-copper sulfide concentrates.** R. J. TRAILL, W. R. MCCLELLAND AND J. D. JOHNSTON. Investigations in Ore Dressing and Metallurgy, Canada Dept. of Mines, Mines Branch, *Rept.* No. 695, 138-53(1929); cf. C. A. 23, 341.—A chalcopyrite-pyrite or pyrrhotite conc. is roasted with excess S present. Elemental S is collected. The calcine is leached with FeCl<sub>3</sub> and the Cu and Fe are removed as chlorides. Cu is pptd. by Fe, roasted (oxidizing), leached with H<sub>2</sub>SO<sub>4</sub>, and electrolyzed. The Fe soln. is freed of Pb, Zn, etc., and electrolyzed to produce pure Fe. Methods for their removal have given inconsistent results and so pure Fe can only be obtained when the ore contains few impurities. A. H. E.

**Foundry iron smelting and remelting parallels.** J. E. FLETCHER. *Fuel Econ. Rev.* 8, 38-47(1929).—In 5 out of 7 furnaces, all producing the same grade of foundry Fe of hematite grade, the wt. of air per lb. of coke C was insufficient completely to convert the C to CO. A properly designed and operated cupola is not a producer of combustible gases. Under this condition the coke expenditure is little more than 5.5% of the Fe melted. A top-gas analysis from 1 cupola may be similar to that from another while the coke consumption per ton of Fe melted, and the rate of melting may be different. H. C. PARISH

**Carbon elimination in the basic Siemens-Marten furnace.** EM. LUBOJATZKY.

*Montan. Rundschau*, 21, 217-8(1929).—The elimination of C in a steel bath is expressed by the following equation  $[2/(1 - 2x)]_x^0 = k_d t$ .  $x$  is the decrease in concn. of C in the melt for an element of time  $t$ , and  $k_d$  is a factor which depends on the kind and size of furnace, excess air, burner construction, fuel and materials such as ore and mill scale used in eliminating C from the bath. Results calcd. by the equation and the detd. values of rates of C elimination are in agreement. C. H. LORIG

**Cupola furnace with water injector.** D. HARR. *Die Giesserei* 25, 567-70(1929).—H<sub>2</sub>O is injected into the cupola through small tubes placed in each tuyère. Each tube has a small specially designed nozzle which forces the H<sub>2</sub>O into the melting zone in a finely divided stream. The advantages of H<sub>2</sub>O in the cupola are: The temp. of the melting zone is raised; coke is saved or the iron and slag are greatly superheated, the amt. of slag is lessened; less S is picked up by the metal; the melting operation is accelerated; the furnace lining has a longer life; and the cost of materials and repairs are reduced. The temp. of the melting zone is raised 50° to 60°. Several probable explanations of the function of H<sub>2</sub>O in combustion reactions are given. It may act as an O<sub>2</sub> carrier according to the equations  $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$  and  $2\text{H}_2 + \text{O}_2 = 2\text{H}_2\text{O}$ , or it is probable that at high temps. the reaction  $2\text{H}_2\text{O} + \text{O}_2 = 2\text{H}_2\text{O}_2$  momentarily takes place. H<sub>2</sub>O<sub>2</sub> reacts with CO to form CO<sub>2</sub> and H<sub>2</sub>O, the latter reaction occurring with a greater velocity than the action of O<sub>2</sub> on CO. C. H. LORIG

**Cupola with water injector, and the Schürmann furnace in continuous operation.** G. OTT. *Die Giesserei* 16, 111-3(1929).—Two cupolas of 1100 mm. diam. were operated at 1350°, first with the addn. of 3 l. of H<sub>2</sub>O per hr. per cupola, and then without the H<sub>2</sub>O addn. The bed and charge coke were accurately weighed. 89,300 kg. of Fe was produced with 8820 kg. coke in the test with H<sub>2</sub>O, while 77,500 kg. of Fe was produced with 9036 kg. coke in the test without H<sub>2</sub>O. The saving in coke requirement was 15% in the test with H<sub>2</sub>O. The operating results with a Schürmann furnace are briefly touched upon. C. H. LORIG

**Open-hearth furnaces of Central and Southern Russia.** K. G. TROUBINE. *Rev. métal.* 26 (Extraits), 231-5(1929).—Data obtained (answers to 162 questions) on 42 Russian open-hearth furnaces are discussed in detail, and numerous formulas deduced as regards construction and operation. **Application of pulverized coal to metallurgical furnaces.** H. W. HOLLANDS AND E. C. LOWNDES. *Colliery Guardian* 139, 226-8, 325-6(1929); *Foundry Trade J.* 41, 41-4. E. H.

**Study of the Bessemer process as practiced in Southern Russia.** V. A. KAMENSKY AND M. A. TATAROV. *Rev. métal.* 26 (Extraits), 227-31(1929).—Results are given of observations of the compn. and temp. of the metal, slag and gases at various stages of the converting (Bessemer) process as carried out in Southern Russia. The process is conducted according to the so-called English method, at a temp. (of the metal) of 1200-1300°, characterized by the production of a metal contg. S 2%, Mn 1%, C 3.5%, P  $\approx$  0.17%, S  $\approx$  0.06%. Under the conditions prevailing in Southern Russia, it would be preferable to use the so-called American method, which would give an Fe contg. 1.2-1.5% Si and 1% Mn. The temp. of the metal is higher than that of the gases at the beginning and lower at the end of the operation. The rise in temp. of the metal at the beginning is due chiefly to combustion of Si and at the end to combustion of C and Fe. The rise in temp. of the flame is due mainly to combustion of CO outside the converter. Other conditions being equal, the rate of elimination of the elements

depends on the temp. When the slag is acid and thick, the Fe is more oxidized at the start than when the slag is fluid. Heat losses by radiation and losses due to the heating of the lining can vary 4-10% of the total amt. of heat and vary with operating conditions.

Methods of testing cast iron. A. LE THOMAS AND R. BOIS. *Foundry Trade J.* 41, 19-21, 32, 46-8, 50, 65-7(1929). E. H.

The influence of graphitization of cast iron. E. DIEFSCHLAG. *Foundry Trade J.* 41, 23-6(1929).—The quality of cast iron is influenced by the chem. compn., by the rate of cooling and the degree of super-cooling, and by the microstructure of the pig iron or scrap used in the remelt unless the remelting temp. is so high as to destroy this structure. On slow cooling, plate-like graphite tends to sep. This interrupts the structure of the metal and reduces the transverse strength. Rapid cooling of a melt confined within certain ill-defined limits of chem. compn. gives a good distribution of graphite eutectic. HANS C. DUUS

**The influence of chromium in cast iron.** J. W. DONALDSON. *Foundry Trade J.* 40, 489-92(1929).—The alloys used were prepd. by adding ferrochrome to an ordinary cast iron, the resulting alloys contg. Cr in amounts up to 0.9%. The addition of the Cr increased the stability of combined C up to 550°; it caused the alloys to decrease in vol. on heat treatment; and it made the alloys slightly less subject to corrosion.

C. L. READ

**The double diagram of the iron-carbon system.** KOTARO HONDA. *Trans. Am. Soc. Steel Treating* 16, 183-9(1929).—An argument, based principally on x-ray data, in favor of the single diagram for the Fe-C system.

W. A. MUDGE

**The Ac<sub>1</sub> range of carbon steel and related phenomena.** AXEL HULTGREN. *Trans. Am. Soc. Steel Treating* 16, 227-56(1929).—A microscopic study was made of the transformation of pearlite into austenite. The three factors causing this transformation to take place in a range are (a) presence of alloy elements, (b) heterogeneity due to segregation on solidification and (c) slow diffusion rate of C, and probably other elements, in a temp. range including and extending beyond, the Ac<sub>1</sub> range.

W. A. M

**The phenomena during the tempering of high-tempered steels.** PIERRE CHIEVE NARD AND ALBERT PORTEVIN. *Compt. rend.* 188, 1670-2(1929).—The authors take exception to the conclusions of previous workers (cf. C. A. 23, 2683) relative to the interpretation of phenomena occurring during the tempering of certain steels (On heating a steel (C 1.5%, Mn 2.26%) above 400° the change is austenite → Fe<sub>3</sub>C + αFe (sorbite); on cooling no reaction occurs because equil. has been established (On heating steel (C 1.5%, Cr 2.26%), austenite → complex carbides of Fe and Cr + austenite with less C; upon cooling austenite → martensite (secondary tempering). These two examples are entirely different, though they show the same effect on the hardness (Brinell increase of 200). They are, however, not characteristic for these classes of steel.

E. R. SCHIERZ

**Investigations on the tenacity and strength of cold-rolled and heat-treated steels of varying previous treatment.** ANTON POMP AND HERMANN POELLEIN. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 11, 155-84(1929).—Steels of different C contents (0.10-1.44%) were tested for tenacity, tensile strength and hardness. The examn of the structure showed no change in spherical cementite, but the lamellar cementite was broken up and sepd. during rolling. During heat treatment cementite tended to form grains, although true grains were not obtained until a temp. of 650° was attained.

HANS C. DUES

**A new method of testing the depth of case on carburized steel.** F. A. FIRESTONE AND E. J. ABBOTT. *Metals and Alloys* 1, 18(1929). The object was to develop a method for testing depth of case without destroying the specimen tested. The actual quantity measured is the difference in magnetic permeability of a standard ring or specimen and a sample ring or specimen being tested. The compn. and heat treatment of the steel influence the magnetic permeability as well as the C content.

A. J. MONACK

**Nickel as an alloying constituent in bearing metal.** CH. L. ACKERMANN. *Metallwirtschaft* 7, 752-3(1928); 8, 81-2(1929).—The effect of Ni in high-Pb bearing metal (69% Pb, 15.5% Sb, 14% Sn, 1.5% Ni) is to increase its resistance to frictional wear. The improvement is ascribed to the formation of Ni<sub>3</sub>Sb<sub>3</sub>. A proper choice of the concns. of Sb and Sn and of such strengthening constituents as As, P and Cd, will produce cheap bearing metals with sufficient impact value and long life. On high-Sn bearing metals (60-82% Sn) Ni exerts a marked hardening effect and increases corrosion resistance; simultaneously the m. p. is raised and the alloy is made brittle. The effect of Ni in Pb-special bronzes is to permit the production of useful bearing metals through the elimination of the miscibility gap between Pb and Cu. These bearing

metals are unexcelled for heavy loads and are suitable where the best phosphor-bronze and the most expensive tin-white metals are inadequate. ROBERT F. MEHL

**Light alloys of high strength.** R. CAZAUD. *Aciers spéciaux* 4, 225-8(1929); cf. C. A. 23, 4179.—C. discusses the use of duralumin type alloys in aviation. A. J. M.

**Corrosion of aluminum and light alloys.** R. CAZAUD. *Aciers spéciaux* 3, 352-60 (1929).—A review. A. J. MONACK

**Have heat-treated aluminum alloys a true endurance limit?** H. W. GILLETT. *Metals and Alloys* 1, 21(1929). A. J. MONACK

**X-ray examination of aluminum at high temperatures.** A. I. ALICHANOV. *Metals and Alloys* 1, 30(1929).—See C. A. 23, 3428. A. J. MONACK

**The mechanism of corrosion.** FRANÇOIS ROEKAERT. *Aciers spéciaux* 3, 346-52 (1929).—R. classifies corrosion as chem., electrochem., and atm. Chem. corrosion may result in coatings of oxides, chlorides, bromides, iodides and sulfides. The effectiveness of oxide coatings in resisting further corrosion depends, in general, upon whether or not the oxide produced is greater or less in vol. than the metal used in producing it. If the vol. of oxide is the greater, corrosion is decreased. Electrochem. corrosion is of 2 types: (1) that which involves an elec. current produced externally and (2) that which does not necessitate the presence of an external elec. current. Atm. corrosion is due to moisture and polluting gases. A. J. MONACK

**Protection against corrosion.** COURNOT. *Bull. soc. franç. élec.* 7, 692-706(1928); *Science Abstracts* 32B, 81.—A review of electrochem. methods. H. L. D.

**Experiences with pipe protection.** C. H. WARING. *Gas Age-Record* 63, 485-6 (1929).—Protective coatings, the proper cleaning of the pipe surfaces and methods of application of the coatings are discussed. LESLIE B. BRAGG

**Corrosion and stainless steels.** ANDRÉ MICHEL. *Aciers spéciaux* 3, 387-97 (1929).—A review. A. J. MONACK

**Corrosion tests.** ALBERT MANGIN. *Aciers spéciaux* 3, 378-80(1929).—A review. A. J. MONACK

**Iron-silicon acid-resisting alloys.** ALBERT MANGIN. *Aciers spéciaux* 3, 374-7 (1929).—A review. A. J. MONACK

**Special corrosion-resisting industrial alloys.** PAUL BRES. *Aciers spéciaux* 3, 368-74(1929).—The following alloys are discussed: I. (1) Fe-Cr, (2) Fe-Cr-Ni, (3) Fe-Si, (4) Fe-Cr-Si alloys; II. (1) Cu-Ni, (2) Cu-Si, (3) Cu-Al alloys; III. (1) Ni-Cr alloys. A. J. MONACK

**Pickling sheets with sulfuric acid before galvanizing.** HEINZ BABLIK. *Iron Coal Trades Rev.* 117, 732-3(1929).—The advantages of  $H_2SO_4$  over HCl for use in pickling operations are that less acid is used and the time required is greatly reduced. Some operating details and cautions are given. LESLIE B. BRAGG

**Methods of covering or coating pipes to prevent corrosion.** W. MOELLER, JR. *Gas Age-Record* 63, 675-6(1929).—A general discussion. LESLIE B. BRAGG

**The place of the complete corrosion survey in industry.** HENRY W. HOUGH. *Gas Age-Record* 63, 172-5, 181-2(1929).—The methods and the utility of a complete study of the sub-soil and other factors bearing on the corrosion of a pipe line, in connection with the application of sufficient corrosion-protective material, are carefully discussed. LESLIE B. BRAGG

**Corrosion surveys for distribution systems.** HENRY W. HOUGH. *Gas Age-Record* 63, 859-60, 867(1929).—A discussion of the methods and utility of the corrosion survey. (Cf. preceding abstract). LESLIE B. BRAGG

**Pipe-line corrosion.** B. B. LEGG. *Gas Age-Record* 63, 551-4(1929).—App. for the coating of pipe with pitch is described and the costs of the coating process and its practical corrosion-prevention results are discussed. LESLIE B. BRAGG

**Spotting of plated or finished metals.** W. P. BARROWS. *Bur. Standards J. Research* 2, 1085-1116(1929); cf. C. A. 23, 43.—Two types of spots are found, "crystal spots" and "stain spots." Crystal spots appear in the form of dendritic crystals on metal finishes contg.  $Cu_2S$ ,  $Ag_2S$  or  $NiS$  and subsequently lacquered. Their formation is caused or accelerated by S in even minute amts., such as may be derived from S or  $H_2S$  in the atm. or from rubber bands, wrapping paper or cardboard cartons. Remedies proposed are exclusion of S, use of certain lacquers which retard spotting, application of a thin film of grease such as petrolatum to the lacquered surface, and the use of waxed paper for wrapping. Stain spots are caused by absorption of acid or alk. compds. in the pores of the metal during plating. This exudes upon the surface later in consequence of absorption of  $H_2O$  and produces the stains. B. suggests reduction of porosity as much as possible, exposure of the articles to a high humidity before the

final finish, and application of a lacquer which is less permeable to moisture than nitro-cellulose lacquers. Phenol condensation lacquers tend to retard stain spotting.

H. STOERTZ

**Artificial corrosion of special Japanese alloys.** DENZO UNO. *Korrosion Metallschutz* 5, 121-30(1929).—Schakudo, a Cu-Au alloy contg. from 0.5 to 10% Au, and schibuizi, a jeweler's alloy of Cu-Ag contg. about 20-25% Ag, were treated with chlorides, chlorates, sulfates, sulfites, sulfides, nitrates, nitrites, carbonates, oxalates, bromides, iodides, fluorides, cyanides, hydroxides, peroxides, acetates, tartrates, citrates, chromates, dichromates, permanganates, arsenites, phosphates and tungstates of various metals, as well as org. and inorg. acids. The desired coloring action is not limited to Cu salts; best results are obtained if the reagent has little solvent action on the alloys. Acids and oxidizing agents are not suitable. The color is said to be due to contact oxidation of Cu atoms in the surface.

H. STOERTZ

**Measuring the corrosion resistance of alclad.** ERICH RACKWITZ AND ERICH K. O. SCHMIDT. *Korrosion Metallschutz* 5, 130-41(1929).—The corrosion resistance of alclad plate is studied in comparison with duralumin and Al plate. Immersion in 3% NaCl contg. 1% H<sub>2</sub>O<sub>2</sub>, and a spray test with 20% NaCl, were used on plates of various thickness and with varying degrees of cold working. The effect of combination with pure Al or duralumin was also studied, and the extent of the attack was measured by loss in wt. as well as decrease in mech. strength. Although the loss in wt. of alclad was of about the same order as that of duralumin, the loss in mech. strength was much less. Plating Al upon duralumin would increase its resistance to corrosion.

**Treating ores.** COMPTOIR TECHNIQUE ALBERT KNAFF ET LEON MAYER and PAUL GREDT. Fr. 655,296, Mar. 23, 1928. Briquets of Mn, Cr, W, V, Mo, Ti, Ni, Co or P ores are made by adding along with the necessary C a lower oxide of Fe or powder metallic Fe and an oxidizing agent. By its oxidation the Fe or lower oxide forms an agglomerating agent, and by its final reduction forms an alloy with the other metal.

**Ore concentration.** ALBERT E. PAUL. Australia 13,657, June 5, 1928. Ores are concd. in a chamber over inclined screen while being subjected to the action of air blown through from below and to a bumping motion, whereby the heavier material moves in an upward direction.

**Ore concentration by flotation.** JAMES L. STEVENS. U. S. 1,722,598, July 30. An ore pulp contg. various minerals is prepd. for flotation by treatment with a material comprising a suitable earthy matter admixed with an alkali metal xanthate or other flotation-collecting agent.

**Froth-flotation concentration of ores.** CARL P. LEWIS (to Minerals Separation North American Corp.). U. S. 1,723,243, Aug. 6. Successive flotation sepn.s. of different floatable constituents such as those of Pb-Zn ores is effected by use of a xanthate and a sol. material such as cresylic acid to effect the flotation of the first constituent floated such as a Pb concentrate and then effecting another flotation sepn. of the other floatable constituent. In this latter sepn., lime,  $\text{CuSO}_4$ , K xanthate and pine oil may be used for effecting the flotation of a Zn concentrate. Cf. *C. A.* 22, 2733.

**Froth-flotation of ores.** ADOLPHE H. NEY. U. S. 1,723,295, Aug. 6. Crushed ore such as sulfidic Cu ore is subjected to froth-flotation in the presence of an alkyl deriv. of thiosulfuric acid such as Na ethyl thiosulfate.

**Apparatus for flotation of ore pulps.** STEPHEN E. MEYER. U. S. 1,722,705, July 30. Structural features.

**Oil for mineral flotation.** ROYER LUCKENBACH. U. S. 1,722,528, July 30. A heavy petroleum residuum 50–70% is mixed with 30–50% of a diluent frother contg. 30–50% pine pitch and kerosene. Cf. *C. A.* 23, 84.

**Separating mixed sulfide ores by flotation.** WILLIAM D. GREEN (to Combined Metals Reduction Co.). U. S. 1,721,993, July 23. Minerals such as those contg. sulfides of Pb, Ag, Zn and Fe are subjected to flotation sepn. in the presence of an "immunizing sulfite" such as  $\text{Na}_2\text{SO}_3$ ,  $\text{CaSO}_3$  or  $\text{ZnSO}_3$  and  $\text{ZnSO}_4$  and in the absence of added free inorg. acid.

**Platinum from ores.** JOSEF SAVELSBERG (to C. Schlesinger & Trier, Kommanditgesellschaft auf Aktien). U. S. 1,723,444, Aug. 6. Ores are heated with reducing agents such as coal and then after cooling are subjected to a magnetic sepn.

**Production of metals.** VEREINIGTE STAHLWERKE A.-G. Fr. 657,865, July 20, 1928. See *Brit.* 294,246 (*C. A.* 23, 1863).

**Roasting zinc blende, etc.** ERZRÖSTUNG GES. *Brit.* 303,055, Dec. 27, 1927. Zn blende or other ore contg. S is roasted in a superposed hearth furnace through which air passes in counter-current to the ore with such regulated velocity that it penetrates the ore layer completely. An app. and various details of operation are described.

**Treating tin-bearing flue dust.** F. KRUPP GRUSONWERK A.-G. *Brit.* 303,144, Dec. 30, 1927. Sn-bearing flue dust is treated in a reverberatory furnace (suitably of the rotary tube type) while kept in motion on the bottom of the furnace, to produce a sintered and purified Sn oxide. Chloridizing may be employed to assist in volatilizing impurities.

**Apparatus for separating iron from slag.** WALTER DIETRICH. Fr. 34,376, Oct. 25, 1927. Addn. to 621,059.

**Pot suitable for carburizing metal articles in cyanide baths.** GROVER R. GREENSLADE, FREDERICK K. LANDGRAF and JOHN R. FLANNERY (to Flannery Bolt Co.). U. S. 1,721,994, July 23. Structural features.

**Binder for use with core sand.** WM. R. PATE and JOSEPH A. GITZEN (to Lindsay-McMillan Co.). U. S. 1,723,982, Aug. 6. Rosin is used with a solvent comprising petroleum derivs. and linseed oil.

**Sand molds and cores.** A. STAHN. *Brit.* 303,858, Jan. 11, 1928. Sand is used (suitably with a small proportion of clay, loam, lime or the like) together with an inorg. binder such as  $\text{H}_3\text{BO}_3$  or  $\text{H}_3\text{PO}_4$  which forms a glassy melt when heated above  $150^\circ$  but below  $400^\circ$  and which loses its binding power at casting temps. above  $1000^\circ$ . An org. binder may also be used.

**Molds of austenitic manganese steel for centrifugal casting of iron and steel, etc.** GUSTAV A. REINHARDT. U. S. 1,722,354, July 30.

**Coating for protecting metal molds.** HARRY P. KIMBER (to Earl Holley). U. S. 1,722,998, July 23. A compn. suitable for coating molds of cast iron comprises an inert refractory material such as powdered chrome ore together with Na chromate or other sol. chromate or Na tungstate which serves as a binding agent. Cf. *C. A.* 23, 1381.

**Linings for metal molds.** L. J. BARTON. *Brit.* 303,205, Aug. 31, 1927. A lining material which can be applied with a brush or the like comprises a powdered refractory material or carbonaceous material mixed with an oily carbonaceous liquid such as a petroleum oil or tar oil. Powdered clay, lime, sand, quartz, bauxite, brick-flotation tailings, coal, coke, charcoal or graphite may be used.

**Chill roll-casting mold.** W. H. NICHOLS. U. S. 1,721,969, July 23. Structural features.

**Ingot mold suitable for casting bimetallic ingots of different steels, etc.** WALTER J. GREEN. U. S. 1,723,345, Aug. 6. Structural features.

**Casting ingots.** A. G. EGLER. Brit. 303,157, Dec. 30, 1927. Ingots are cast in molds supported on a platform which is jarred while the metal is molten. An app. is described.

**Apparatus for casting metal ingots.** ALEXANDER W. CARROLL. U. S. 1,723,601, Aug. 6. Structural features.

**Apparatus for making small castings.** PAUL A. PITMAN. U. S. 1,723,071, Aug. 6. Structural features.

**Die casting.** WILLIAM J. DURING (to Precision Castings Co.). U. S. 1,722,281, July 30. In producing die-cast articles, such as those of an alloy contg. Al 92, Cu 3 and Ni 5%, a wooden core is supported within a die and the molten die-casting metal is forced into the die under high pressure at a temp. higher than the combustion point of wood. An app. is described.

**Casting copper alloys in metal molds.** CARL ADEY and CARL PIEL. U. S. 1,722,124, July 23. Mech. features.

**Core-roasting furnace with horizontal retorts arranged one above another.** RAY A. BENNETT. U. S. 1,723,006, Aug. 6. Various structural features are described.

**Rotary furnace for roasting or reducing ores.** C. P. DEBUCH. Brit. 303,072, July 27, 1927. Structural features.

**Rotary furnace for roasting or reducing ores.** C. P. DEBUCH. Brit. 303,096, July 27, 1927. Structural features of a furnace adapted for treating Zn blende, etc.

**Cupola furnace suitable for melting non-ferrous metals.** D. CUSHING. Brit. 303,042, Sept. 26, 1927. Structural features.

**Blast-furnace operation.** S. G. ALLEN. Brit. 303,206, Aug. 30, 1926. An oxygenated blast is used such as would ordinarily cause an excessive smelting capacity as compared with shaft-reduction capacity, and the ratio of ore to coke in the charge is proportionately increased. If the shaft temp. becomes too low, addnl fuel such as powdered coal or fuel oil may be introduced above the mantle. Brit. 303,207 relates to the production of ferro-alloys in blast furnaces by a similar process in which a blast is used so enriched with O that the temp. of the exit gases is preferably about 150°. Production of ferro-Mn is described.

**Furnace for heat-treating metal shapes, etc.** ERNST WIRZ (to Akt.-Ges. Brown, Boveri & Cie). U. S. 1,723,319, Aug. 6. Structural features.

**"Normalizing" furnace for treating metal sheets.** FRANK J. WINDER (to Surface Combustion Co.). U. S. 1,723,109, Aug. 6. Structural features.

**Hearths of metallurgical furnaces.** HIRSCH, KUPER, UND MESSINGWERKE A. G. (to Vakuumschmelze Ges. and W. Rohn). Brit. 303,417, Jan. 2, 1928. In the process described in Brit. 226,801 (C. A. 19, 2116), for production and repair of hearths of metallurgical or other furnaces, a quartzite is used consisting of small grains of quartz cemented together by a siliceous binding material.

**Converter for desulfurizing and dephosphorizing pig iron.** CARBONISATION SOC. GÉNÉRALE D'EXPLOITATION DES CARBONES. Brit. 303,891, Jan. 12, 1928. Various structural features and details of procedure are described.

**"Normalizing" iron and steel sheets.** HOWARD T. GRAFTON (one-third each to Wm. R. Grimsley and Jay S. Irvin). U. S. 1,723,152, Aug. 6. Mech. features relating to normalizing sheets in packs.

**Molybdenum steels with a nitride-hardened surface.** HENRY A. DEFRIES (to Ludlum Steel Co.). U. S. 1,723,015, Aug. 6. Articles are formed with nitride hardened surfaces from steel substantially free from Al and contg. Cr 1-9, Si 0.5-3.5, Mo 0.15-2.0 and C 0.1-1.0%.

**Purifying metals and alloys.** F. W. CORSALLI. Brit. 303,094, June 23, 1927. In a process of purifying and refining molten metals and alloys as described in Brit. 297,759 (C. A. 23, 2690), the metal is conveyed directly into a collecting vessel in which it is submitted to an "intershaking," swinging or dashing movement produced by an eccentric device. An app. is described.

**Alloys.** HÜTTENWERK NIEDERSCHÖNEWEIDE A.-G. Fr. 657,940, July 21, 1928. The liquation of substances contg. Sn, Pb, Sb and Cu is carried out in a trough-shaped furnace heated from above, the thickness of the layer of material being such that the parts liquefied in the upper part of the charge undergo, in their passage through the charge, repeated solidification and liquefaction. Cf. C. A. 23, 1863.

**Alloy for electrical conductors.** MICHAEL G. KORSUNSKY (name changed to Michael G. Corson) (to Electro Metallurgical Co.). U. S. 1,723,867, Aug. 6. An alloy of Cu contg. Cr 0.5-3.0%, in a condition in which it has high tensile strength, is subjected to an annealing operation at 400-700° for such time that the cond. of the cold

alloy is increased to at least 75% M.S. and the tensile strength is not reduced below 70,000 lbs. per sq. in.

**Aluminum alloy.** PIERRE BERTHELEMY and HENRY DE MONTBY. U. S. reissue 17,385, July 30. See original pat. 1,599,869 (C. A. 20, 3442).

**Antimony alloys.** H. HARRIS. Brit. 303,328, May 29, 1928. Alloys such as those of Sb with Pb are purified by bringing the molten alloy into intimate contact with a mixt. of caustic alkali and alkali chloride such as NaOH and NaCl at temps. between the m. p. of the alloy and 550°. Other auxiliary treatments also are described.

**Copper alloys.** METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 303,684, Feb. 29, 1928. Cu alloys are described contg. Ni and Fe and 1-4% of Si. The quantity of Ni is preferably 1-5% and Fe 4-6% and other metals may be added such as Zn up to 20%, Al, Mn and Sn up to 1% of each, and up to 0.5% of an alkali or alk. earth metal. The alloy may be annealed at 750-950° and is then quenched and drawn at 350-600°. Cf. C. A. 23, 594.

**Copper-cobalt alloy.** MICHAEL G. CORSON (to Electro Metallurgical Co.). U. S. 1,723,922, Aug. 6. The phys. strength of Cu is improved by alloying it with Co 2-5%, heating the alloy to above 850° and quenching from that temp.

**Alloy containing copper, magnesium and manganese.** EDWARD C. BURDICK (to Dow Chemical Co.). U. S. 1,721,768, July 23. A relatively small proportion of cupro-Mn contg. Cu and Mn in approx. the ratio of 7:3 is interfused with Mg.

**Alloy of lead, antimony and arsenic.** KAARE S. SELJESAETER (to Western Elec. Co.) U. S. 1,722,358, July 30. Alloys which are suitable for battery grids, bearings and sheaths for elec. cables, etc., are formed of Pb together with not more than 4% Sb and not more than 1% As. Cd, S, Bi, Te and Tl may be used instead of As.

**Iron-nickel alloys.** F. KRUPP A.-G. Brit. 302,994, Dec. 24, 1927. Fe-Ni alloys of high sp. resistance and high initial permeability contain about 33-48% Ni and 0.3-5.0% Si.

**Alloy steel.** FREDERICK C. LANGENBERG. U. S. 1,723,868, Aug. 6. An alloy steel which forms sound castings of high strength contains Mn 3% or less and Mo 1.25% or less and Zr 0.1-0.5%.

**Treating copper-nickel mat.** F. F. LATHE. Brit. 303,066, Dec. 27, 1927. Various details of refining Cu-Ni mat and auxiliary treatments for recovery of precious metals, etc., are described. Cf. C. A. 22, 2735.

**Reclaiming metal from electrical condensers or similar materials.** CECIL A. HALLAM (to Western Elec. Co.). U. S. 1,722,372, July 30. In treating articles comprising metal foil and waxed paper or like materials, combustible material present is ignited to melt the metal forming a part of the material and to exert a sufficient reducing action to prevent oxidation of the metal, the latter is sepd. (in an app. which is described) with assistance of agitation, and deposition of the residue and of the metallic material is effected in the same receptacle.

**Treating tinned scrap iron carrying lead peroxide.** ARTURO DOSSMANN. U. S. 1,723,414, Aug. 6. See Brit. 298,103 (C. A. 23, 2692).

**Hardening metals.** HEINRICH LINDHORST. Fr. 34,217, Oct. 10, 1927. Addn. to 640,681 (C. A. 23, 809). Metals are hardened by placing them with a powder which afterward volatilizes in a closed container. The powder, which may be carbonized leather, BaCO<sub>3</sub> and NH<sub>3</sub>, is preferably agglomerated into briquets so that the exact amt. required may be used.

**Hard material for tools and dies.** F. C. KELLEY (to British Thomson-Houston Co., Ltd.). Brit. 303,751, Jan. 7, 1928. A mixt. of W, Co and C (with or without a temporary binder) or similar materials is heated to a sintering temp. Various details are given.

**Hardening steel molds, etc.** INTERNATIONAL DE LAVAUD MFG. CORP., LTD. Brit. 303,487, Jan. 6, 1928. The surface of smooth-finished steel articles such as molds used for centrifugal casting of pipes is hardened (with only microscopic roughening) by impact from hard metal balls of small diam. An app. is described.

**Apparatus for hardening the heads of railway rails.** EISENWERK-GES. MAXIMILIANSHÜTTE. Brit. 303,739, Jan. 7, 1928. An app. is described by which the heads of the rails are immersed in liquid held in troughs. Cf. C. A. 23, 809.

**Steel car wheels of high-manganese, pearlitic steel containing 0.5-2% chromium.** WINFIELD C. HAMILTON and CLARENCE E. SIMS (to American Steel Foundries). U. S. 1,721,555, July 23.

**Apparatus for heat treatment of metal conductors such as those loaded with magnetic alloy.** GUSTAF W. ELMEN (to Western Electric Co.). U. S. 1,722,079, July 23. Structural features.

**Apparatus for heat-treating and quenching metal rods, tubes, etc.** GEORGE E. BARNHART. U. S. 1,722,449, July 30. Structural features.

**Heat-treating magnetic alloys such as those of nickel with iron.** BELL TELEPHONE LABORATORIES, INC. Brit. 303,928, Oct. 14, 1927. The permeability of materials such as alloys contg. over 60% Ni, with Fe, and having high permeability at low magnetizing forces with low hysteresis losses as compared with Fe, is made substantially const., for magnetizing forces up to at least 0.1 gauss, by heating to 600-900° for at least 2 hrs. and then permitting cooling at a rate not greater than 10° per min. Small quantities of Cr or other suitable substances may be added to the alloy to increase its resistivity.

**Pickling bath.** JOSEPH G. DAVIDSON (to Carbide & Carbon Chemicals Corp.) U. S. 1,723,923, Aug. 6. A hydroxyalkylamine such as a mixt. of tri- and di-ethanolamines is used as an inhibitor in pickling baths such as those contg.  $\text{H}_2\text{SO}_4$  and used for treating metals such as iron and steel.

**Apparatus for pickling metals.** CHARLES W. KINTER. U. S. 1,722,001, July 23. Structural features.

**Wires and tapes for loading telephone conductors.** WILLOUGHBY S. SMITH and HENRY J. GARNETT. U. S. 1,723,215, Aug. 6. C-free loading wires or tapes are formed of Ni 30-33, Fe 58-65 and Cu 2-6%.

**Drawn tungsten wire.** RICHARD JACOBY (to General Elec. Co.). U. S. 1,723,862, Aug. 6. A filament is produced having zones of longitudinally disposed crystals, one surrounded by the other, the crystals in one zone overlapping the crystals in the other, and with each zone forming a longitudinal section of the filament distinguishable from the other. Cf. C. A. 22, 359.

**Colored coatings on metal articles by dipping.** ALADAR PACZ. U. S. 1,723,067, Aug. 6. Metal articles such as iron, steel, Sn, Al, Pb and Mg are dipped in a soln. contg. Na molybdate or other suitable sol. molybdate and a sol. F compd. such as Na fluosilicate which produces a dense protective colored coating on the material. Oxalates or  $\text{AlCl}_3$  may be used in some cases. Cf. following abstr.

**Coating and coloring metals.** A. PACZ. Brit. 302,943, June 22, 1927. Metallic articles formed mainly of metals such as Fe, Al, Sn, Pb, Zn, Mg or Cd are treated with a soln. contg. a sol. molybdate and a salt of oxalic, polysilicic, hydrofluoric or fluosilicic acids (in the absence of a simple salt of a metal of the Fe group other than Fe). Iron articles may be coated with Cu and then treated with a soln. contg. a sol. molybdate and fluoride and the articles may be subsequently treated with a soln. of chromates. In treating Zn and Cd  $(\text{NH}_4)_2\text{SO}_4$  is mixed with the molybdate before use. Al is pickled with a fluosilicate soln. before coating. Cf. preceding abstr.

**Coating metals with nitrocellulose and synthetic resin.** CARLETON ELLIS (to Ellis-Foster Co.). U. S. reissue 17,379, July 23. See original pat. 1,529,056 (C. A. 19, 1502).

**Coating ferrous metals with chromium or cobalt.** I. G. FARBENIND. A. G. Brit. 303,034, June 25, 1927. The metal is preliminarily coated with Ni, Cr or Co as a diffusing agent and the diffusion is effected in an inert atm. such as H or *in vacuo* at temps. at which the diffusing metal does not melt; e. g., iron is coated with a thin deposit of Ni plated with Cr and heated at 1100-1300° for several hrs. in H.

**Coating ferrous metal sheets with zinc and aluminum.** EARL R. WEHR, CARL C. MAHLIE and JOHN R. CAIN (to American Rolling Mill Co.). U. S. 1,722,949, July 30. The sheets are passed through a flux and into a bath of molten Zn and thence through a molten alloy of Zn and Al floating on the surface of the Zn. An app. is described.

**Forming superposed designs on metal plates.** WILLIAM H. WHEELER (to Fedco Number Plate Corp.). U. S. 1,722,778, July 30. A removable coating such as a varnish is applied to certain parts of a plate of Cu or other metal carrying a design, and a metal of different color such as Ni is applied to the remaining parts of the surface, a second design is embossed over the first, and the removable coating is then removed.

**Protecting copper.** SOC. CHIM. DES USINES DU RHÔNE. Fr. 34,166, Sept. 20, 1927. Addn. to 629,906. Vessels made of Cu or alloys thereof are protected against the action of org. acids, particularly AcOH, by adding  $\text{K}_4\text{Fe}(\text{CN})_6$  or other substances capable of pptg. Cu in acid medium.

**Inhibiting rust of ferrous metals.** R. FIBERHARD. Brit. 303,035, July 26, 1927. A rust-inhibiting compn. is prepd. by dissolving in  $\text{CH}_2\text{O}$  or other water-sol. compd. of aldehydic character a compd. produced by reducing with uric acid one or more compds. of Cr, Mo or W in the acidic state or of these metals or of Pb in the oxidic or peroxidic state. The reduction with  $\text{CH}_2\text{O}$  is effected in the presence of a catalyst such as powd.

the parts is mixed with a brazing flux and binder which may contain powdered Cu and Fe, borax and water and the whole mass is heated nearly to the m. p. of the copper section and molten brass is introduced within the pocket recess, followed by slow cooling of the united parts.

**Flux holder for welding operations.** JOHN C. LINCOLN (to Citizens Savings & Trust Co.). U. S. 1,722,929, July 30. A semi-permanent holder such as a metal or paper tube carries a predetd. charge of solid fluxing material such as  $\text{Na}_2\text{CO}_3$  with which is incorporated an air-excluding protective material, *e. g.*, resin.

**Arc-welding electrodes.** ALLOY WELDING PROCESSES, LTD., AND E. H. JONES. Brit. 303,996, Dec. 13, 1927. The coating of a metallic arc-welding electrode is provided with a film impermeable to moisture which may be formed by dipping the coated electrode in a cellulose acetate or nitrocellulose varnish or by mixing such a varnish or lacquer with the materials of which the coating is formed. Various compns. and details are described. Cf. *C. A.* 23, 3896.

**Welding and soldering composition.** CHRISTOPH DÜRSCH. U. S. 1,722,040, July 23. A compn. suitable for use in uniting metals such as cast iron, Al, Cu or brass is formed by melting together brass, lead and borax 1 part each and mixing this mixt. with a second mixt. prepd. from powdered borax 1, pulverized soda 1 and pure salt 0.2 part and with water to form a paste.

**Soldering composition.** KARL GEISEL (to Aluminum Solder Corp. of America). U. S. 1,721,814, July 23. A compn. having a soldering temp. of about  $260^\circ$  which is suitable for soldering Al and Al-alloy castings comprises approx. Al 4.3, Zn 66.7 and Sn 29.0%.

## 10—ORGANIC CHEMISTRY

CHAS. A. ROULLER AND CLARENCE J. WEST

The saturation capacity of rosin acids. IV. B. M. MARGOSCHES, K. FUCHS AND W. RUZICKA. *Chem. Umschau Fette, Oele, Wachse u. Harze* 36, 115-8 (1929).—Grün and Jancko showed that in the I no. detn. of rosin by iodometry a larger quantity of acid is found than can be explained by substitution, which probably has its origin in the splitting off an added halogen; pinene shows the same phenomenon and probably has the same unsatd. character, so that abietic acid also possesses a bridge bond and double bond. Then abietic acid is the result of a union of 1 mol. of  $\alpha$ - and  $\beta$ -pinene to form  $\text{C}_{20}\text{H}_{32}$  which on oxidation becomes I,  $\text{C}_{20}\text{H}_{30}\text{O}_2$ . Ruzicka's formula is based on the fact that abietic acid furnished an I no. that corresponds with the theory, indicating no substitution but a complete satn. of the bonds. If the  $\text{CO}_2\text{H}$  group were adjacent to the double bond (tertiary position) the latter would not be fully satd. in the I no. detn. But because of the difficulty of esterifying a primary union, the  $\text{CO}_2\text{H}$  group must be in a secondary position at some distance from the double bond.

(I)

(II)

Ruzicka reduced a Me ester of abietic acid; no hydrogenation occurred, but would have taken place if  $\text{CO}_2\text{H}$  had been adjacent to the double union. By fixing the  $\text{CO}_2\text{H}$  position through a series of reactions with  $\text{PCl}_5$  upon abietinol, the formula II has been worked out. With the exception of the *d*-primary acid all of the acids can be converted into the *l*-form of abietic acid, m.  $158^\circ$ . P. ESCHER

**Autooxidation of hydrocarbons.** P. DUMANOIS AND P. MONDAIN-MONVAL. *Bull. soc. ind. Mulhouse* 95, 243-72 (1929).—See *C. A.* 23, 2694. A. PAPINEAU-COUTURE

The connection between the zig-zag structure of the hydrocarbon chain and the alterations in the properties of odd- and even-numbered chain compounds. ALEX MÜLLER. *Proc. Roy. Soc. (London)* A124, 317-21(1929); cf. *C. A.* 23, 30.—Distinct structural differences between the odd and even members of hydrocarbon chains are shown by models. The alterations of the properties between odd- and even-numbered substances such as no. of mols. along the "c" axis, crystal habit, angle  $\beta$ , m. p., mol. vol., heat of crystn. and lattice energy are attributed to these differences.

**Melting points of normal paraffins.** J. H. HILDEBRAND AND A. WACHTER. *J. Am. Chem. Soc.* 51, 2487-8(1929).—A criticism of the m. ps. reported by Levene, West and van der Schuer (C. A. 9, 1610) for certain normal paraffins. From a curve of m. ps. of the hydrocarbons contg. 19 to 36 C atoms, the following "best values" are suggested (no. of C atoms and m. p. given): 19, 32°; 20, 36.5°; 21, 40.5°; 22, 44°; 23, 47.5°; 24, 51°; 25, 54°; 26, 57°; 27, 59.5°; 28, 62°; 29, 64°; 30, 66°; 31, 68°; 32, 70°; 33, 72°; 34, 73.5°; 35, 75°; 36, 76°.

**Polymerization and ring formation. I. Introduction to the general theory of condensation polymers.** WALLACE H. CAROTHERS. *J. Am. Chem. Soc.* 51, 2518-59 (1929).—Linear polymers conform to the type  $-R-R-R-R-$ , etc., which is characterized by a recurring structural unit. The structural unit  $R$  is a bi-valent radical. Two types of polymers are recognized. (1) Addn. or A polymers, the polymeric mol. is converted by heat into a monomer having the same compn as the structural unit, or the polymer is formed by the mutual addn. of a no. of such monomers. (2) Condensation or C polymers: the polymeric mol. is converted by hydrolysis or its equiv. to a monomer which differs in compn from the structural unit by one  $H_2O$  (or  $HCl$ ,  $NH_3$ , etc.). or the polymeric mol. is formed from nos. of the monomers by a process of polyintermol. condensation. Rubber, polystyrene, polyoxymethylene and paracetaldehyde are A polymers. Cellulose, silk fibroin and hexaethylene glycol are probably C polymers. Substances of the type  $x-R-x$  and  $y-R-y$  are called bifunctional. In these formulas  $-R-$  represents a bivalent radical and  $x$  and  $y$  are functional groups capable of reacting with each other in a known fashion to form the new functional group,  $z$ . Reactions of the type  $x-R-y \rightarrow \text{product}$  are called bifunctional and those of the type  $x-R-x + y-R-y \rightarrow \text{product}$  are called bi-bifunctional. Such reactions will lead to compds. contg. the structural units  $-R-z-$  and  $-R-z-R-z-$ . Bifunctional reactions will be intramol. and will lead to

the monomeric product,  $R-z$  when this can be a 5- or 6-ring. If the monomeric product

can only be a larger-than-6-ring, reaction will usually be intermol. and the product a polymer of the type,  $-R-z-R-z-R-z-R-z-R-z-$ , etc. II. Polyesters. W. H. CAROTHERS AND J. A. ARVIN. *Ibid* 2560-70.—The following esters have been prepd. by heating the acid and 5% excess of the glycol for about 3 hrs. at 175-85° and then at 200-50° and 0.2 mm. for 3 hrs. *Ethylene malonate*, liquid; *succinate*, m. 108°; *adipate*, m. 50°; *sebacate*, m. 79°; *trimethylene succinate*, m. 52°; *adipate*, m. 45°; *sebacate*, m. 56°; *hexamethylene succinate*, m. 57°; *adipate*, m. 56°; *sebacate*, m. 57°; *decamethylene succinate*, m. 58°; *adipate*, m. 77°; *sebacate*, m. 74°; *ethylene trimethylene*, *hexamethylene* and *decamethylene phthalates*, and *ethylene fumarate* and *maleate*. That the esters are not monomeric is indicated by their phys. properties and by their mol. wts. The lowest mol. wt. observed for any of the solid esters was 2300 and the highest 5000; the mean of all detns. is 3200. Such a mol. wt. corresponds with a value of 8 to 20 (depending on the length of the chain of the structural unit) for  $n$  in the general formula  $-(CO.R'.CO.O.R''.O-)_n-$ . While the disposition of the valences at the ends of the chains in the above formula cannot be definitely decided, it is provisionally assumed that  $HO$  groups are present at each end of the chain because of the presence of 1 more mol. of glycol than acid; the analytical values agree more closely for such a formula than for a cyclic formula. The phys. properties of these compds. are discussed.

**Synthesis of the isomeric 2-butenes.** WM. G. YOUNG, ROBERT T. DILLON AND HOWARD J. LUCAS. *J. Am. Chem. Soc.* 51, 2528-34(1929).—Starting with  $MeEtCO$ , the *cis*- and *trans*-2-butenes have been synthesized in a high state of purity. Necessary details are given for the prepn. and purification of the intermediate compds. ( $EtCH(OH)MeCO_2H$ , angelic and tiglic acids and their  $HI$  addn. compds.).

**Reaction between dichloroacetic acid and amylenes.** L. M. ANDREASOV. *Ukrainski Khim. Zhur.* 4, Sci. Pt., 93-4(1929).—A study was made of the reaction between amylenes and  $Cl_2CHCO_2H$  at 18° in the following solvents: benzene,  $CHCl_3$ ,  $CS_2$ .

EtOH and ether. The reaction did not proceed in presence of alc. or ether. In the presence of the other above-mentioned compds. it progressed very slowly. According to the velocity of reaction, the highest rate was observed in the presence of benzene, medium in  $\text{CHCl}_3$  and lowest in the presence of  $\text{CS}_2$ . ROBERT SCHLESS

**The limit of reaction of formation of trichloroacetoamylic ester in a mixture of solvents.** L. M. ANDREASOV. *Ukrainski Khim. Zhur.* 4, Sci. Pt., 89-92(1929); cf. C. A. 23, 3145, 3207.—A study was made of the limits of reaction between amylene and  $\text{Cl}_3\text{CCO}_2\text{H}$  in mixts. of solvents:  $\text{C}_6\text{H}_6\text{-CCl}_4$  and  $\text{CCl}_4\text{-CS}_2$  at  $25^\circ$ . These solvents are inactive, i. e., they do not lower the limits of esterification, and it was expected that the limits of reaction between amylene and  $\text{Cl}_3\text{CCO}_2\text{H}$  in a mixt. of inactive solvents should follow a straight line. This was not confirmed by expts.; they follow a curve the shape of which depends on the concn. of the reacting substances. ROBERT SCHLESS

**The preparation of amylene with a theoretical hydrogen value.** H. I. WATERMAN, P. VAN'T SPYKER AND H. A. VAN WESTEN. *Rec. trav. chim.* 48, 612-5(1929).—Amylene with a theoretical H value was prepd. from a Kahlbaum prepn. of amylene which on fractional distn. gave a fraction b.  $36^\circ$  with  $n_D^{20^\circ}$  1.3786,  $n_D^{20^\circ}$  1.3811,  $n_F^{20^\circ}$  1.3872 and  $n_F^{20^\circ}$  1.3924, the Br value being 208.4 (calcd. 228.1). On bromination in  $\text{CCl}_4$  with the theoretical amt. of Br, a mixt. of bromides was obtained in 50% yield,  $b_{17}$   $58\text{--}62.5^\circ$ . This mixt. was debrominated by heating with water and a freshly prepd. Zn-Cu couple, an amylene being obtained in 50% yield which  $b_{780}$   $36.8\text{--}8.4^\circ$ ,  $n_D^{20^\circ}$  1.3830,  $n_D^{20^\circ}$  1.3856,  $n_F^{20^\circ}$  1.3918 and  $n_F^{20^\circ}$  1.3973, had a Br value of 229.0 (calcd. 228.1), a thiocyanogen Br value of 228.5 (calcd. 228.1) (cf. Kaufmann, C. A. 22, 4845) and a H value of 100.8% (cf. Waterman, Perquin and van Westen, *J. Soc. Chem. Ind.* 47, 363T(1928)). The pentane obtained on hydrogenation had a Br value of 0.1,  $n_D^{20^\circ}$  1.3526,  $n_D^{20^\circ}$  1.3545 and  $b$   $28.85^\circ$ . According to the consts. given in the literature for several pentanes, this pentane chiefly consists of 2-methylbutane and it may, therefore, be assumed, that the original amylene prepn. consists chiefly of 2-methyl- $\Delta^2$ -butene.

C. F. VAN DUIN

**The additive properties of  $\alpha$ -diacetylenic hydrocarbons.** V. GRIGNARD AND TCHÉOUFAKI. *Compt. rend.* 188, 1531-4(1929); cf. C. A. 23, 2931.—Tetradeca-6,8-diene (I) with  $\text{Br}_2$  at room temp. yields  $\text{C}_{14}\text{H}_{22}\text{Br}\cdot\text{CBr}\cdot\text{CBr}\cdot\text{CBr}\cdot\text{C}_6\text{H}_{11}$ , m.  $118^\circ$  with resinification. At  $5^\circ$  there results a yellow liquid,  $\text{C}_{14}\text{H}_{22}\text{Br}_2$ , which darkens rapidly and on distn. gives 1-bromoheptene and a resin. Diphenyldiacetylene with  $\text{H}_2$  in  $\text{Et}_2\text{O}$ -EtOH with Pt O yields 20% *cis-cis*-diphenylbutadiene, 20% dibenzylacetylene and a liquid,  $b_{14}$   $185.7^\circ$ , which in light yields *trans*-diphenylbutatriene (II), m.  $95^\circ$ , which with  $\text{O}_3$  and then  $\text{Na}_2\text{SO}_4$  yields  $\text{BzH}$ . I with  $\text{HBr}$  yields 1,4-diphenyl-1-bromobutatriene, m.  $92^\circ$ , which on reduction yields II. All these addns. are 1,4. V. F. H.

**1,12-Dodecanediol and the diacetylenic hydrocarbons  $\text{C}_{14}\text{H}_{20}$  and  $\text{C}_{20}\text{H}_{34}$ .** R. LESPIEAU. *Bull. soc. chim.* 43, 1189-93(1928); cf. C. A. 19, 1850.—In addn. to the results given in C. A. 23, 817, the following work is reported.  $(\text{CH}_2)_7(\text{MgBr})_2$  (prepd. from  $(\text{CH}_2)_7\text{Br}_2$  and Mg) and  $\text{Br}(\text{CH}_2)_7\text{Br}$  give  $\text{CH}_3\cdot\text{CBr}(\text{CH}_2)_9\text{CBr}\cdot\text{CH}_3$  (I),  $b_{16}$   $180^\circ$ ,  $d$  1.274,  $n_D$  1.497, and  $\text{CH}_3\cdot\text{CBr}(\text{CH}_2)_{16}\text{CBr}\cdot\text{CH}_3$ ,  $b_{11}$   $249\text{--}52^\circ$ ,  $d$  1.120,  $n_D$  1.4915. I and alc. KOH give  $\text{CH}_3\cdot\text{C}(\text{CH}_2)_9\text{C}\cdot\text{CH}_3$ ,  $b_{12}$   $115.5^\circ$ , m.  $-3^\circ$  to  $-2^\circ$ . Analogously  $\text{CH}_3\cdot\text{C}(\text{CH}_2)_{16}\text{C}\cdot\text{CH}_3$  (II), m.  $54.6^\circ$ , was prepd. II and  $\text{AgNO}_3$  form  $\text{C}_{20}\text{H}_{32}\text{Ag}_2\cdot\text{CH}_3\cdot\text{C}(\text{CH}_2)_7\text{C}\cdot\text{CH}_3$ ,  $\text{EtMgBr}$  and  $\text{CO}_2$  give  $\text{CO}_2\text{HC}\cdot\text{C}(\text{CH}_2)_9\text{C}\cdot\text{CCO}_2\text{H}$  (III), m.  $111.5\text{--}2.5^\circ$ . III and H in the presence of Pt black give  $\text{CO}_2\text{H}(\text{CH}_2)_{11}\text{CO}_2\text{H}$ .

FREDERICK C. HAHN

**The partition of sodium between sodium hydroxide and sodium ethoxide or sodium methoxide in ethyl alcohol or methanol sodium hydroxide solutions.** J. M. F. CAUDRI. *Rec. trav. chim.* 48, 589-92(1929).—A peculiar sapon. curve was observed in the hydrolysis of phthalide with NaOH in aq. alc. solns. when the alc. content was between 50 and 80 vol. %, and an explanation of this fact was sought in the possible large diminution of the NaOEt on account of the formation of NaOH, when a little water is added to abs. alc. solns. (cf. C. A. 23, 3393). This hypothesis is supported by an investigation of Kremann (*Monatsh.* 26, 279(1905)) on the alk. sapon. of AcOEt in mixts. of MeOH, EtOH and PrOH and water. With increasing % of water the curve representing the connection between the reaction const. and the % of water added, is initially very flat with MeOH, somewhat steeper with EtOH and much steeper with PrOH, especially the latter curve being similar in shape to the curves found by C. (l. c.) for the hydrolysis of phthalide in mixts. of EtOH and water. It is concluded therefore that these similar curves emanate from a similar cause. The conclusion that NaOEt is decompd. to a considerable extent in abs. alc. soln. on the addn. of water

is in conflict with the assumption of Lobry de Bruyn and Steger (*Rec. trav. chim.* 18, 311(1899)) that even in dil. aq. alc. solns. of NaOH the Na is present chiefly in the form of the ethylate. These authors found that the addn. of water diminished the velocity of ether formation from alkyl iodides and NaOEt in EtOH while in MeOH the velocity of etherification first increased on the addn. of water, passed through a max. and then decreased again. C. has already shown (*l. c.*) that the conclusion of L. de B. and S. is not justified when subjected to a more searching math. investigation and now puts forward the following explanation. It is assumed that the velocity of ether formation in alcs. will be increased on the addn. of water just as is the case with the alcoholysis and hydrolysis of  $\text{Ac}_2\text{O}$  (to be published later by C.) and also, most probably, with the hydrolysis of esters by NaOH in mixts. of water and org. solvents (except alcs.), which may be compared with ether formation when the abnormal effect which has been attributed to the action of "dry" ions or mols., does not manifest itself. Alongside this increase there occurs also a decrease due to the reduction of the quantity of alcoholate, which is partly decompd. by water. If the above conclusion is correct, it at once follows that the decompn. of NaOEt in abs. alc. on the addn. of water, is fairly considerable, while the decompn. of NaOMe in aq. MeOH is much less. This is in agreement with the expts. of Kremann, mentioned above.

C. F. VAN DUIN

**Freezing temperature of organic compounds. XI. Compounds in  $\text{C}_6$  and  $\text{C}_8$ .** IWAN SIMON. *Bull. soc. chim. Belg.* 38, 47-70(1929).—Numerous phys. properties of 19 very pure compds. have been tabulated. The degree of accuracy is specially good. Among the most important data given: AmOH, m.  $-78.5^\circ$ , b. (cor.)  $138.00^\circ \pm 0.02$ ,  $d_4^{20}$  0.82897,  $d_4^{15}$  0.81837,  $d_4^{30}$  0.80764; AmCl, m.  $-99^\circ$ , b.  $108.35^\circ \pm 0.02$ ,  $d_4^{20}$  0.90137,  $d_4^{15}$  0.88657,  $d_4^{30}$  0.87163; AmBr, m.  $-95.25^\circ$ , b.  $129.70^\circ \pm 0.02$ ,  $d_4^{20}$  1.24264,  $d_4^{15}$  1.22367,  $d_4^{30}$  1.20456; AmI, m.  $-85.6^\circ$ , b.  $157.00^\circ \pm 0.02$ ,  $d_4^{20}$  1.54572,  $d_4^{15}$  1.52381,  $d_4^{30}$  1.50181;  $\text{Am}_2\text{S}$ , m.  $-51.33^\circ$ , b.  $230.1^\circ \pm 0.05$ ,  $d_4^{20}$  0.85538,  $d_4^{15}$  0.84394,  $d_4^{30}$  0.83243; AmPh, m.  $-78.25^\circ$ , b.  $205.3^\circ \pm 0.1$ ,  $d_4^{20}$  0.87411,  $d_4^{15}$  0.86261,  $d_4^{30}$  0.85100;  $\text{C}_{10}\text{H}_8$ , m.  $-30.1^\circ$ , b.  $173.75^\circ \pm 0.05$ ,  $d_4^{20}$  0.74571,  $d_4^{15}$  0.73443,  $d_4^{30}$  0.72306; AmH, m.  $-91.5^\circ$ , b.  $103.7^\circ \pm 0.1$ ; AmCN, m.  $-79.4^\circ$ , b.  $163.95^\circ \pm 0.02$ ,  $d_4^{20}$  0.82157,  $d_4^{15}$  0.80939,  $d_4^{30}$  0.79710;  $\text{AmCO}_2\text{H}$ , m.  $-3.9^\circ$ , b.  $205.35^\circ \pm 0.02$ ,  $d_4^{20}$  0.94423,  $d_4^{15}$  0.93136,  $d_4^{30}$  0.91832;  $\text{AmCO}_2\text{Et}$ , m.  $-67.5^\circ$ , b.  $167.85^\circ \pm 0.02$ ,  $d_4^{20}$  0.88956,  $d_4^{15}$  0.87583,  $d_4^{30}$  0.86196;  $\text{AmCOCl}$ , m.  $-87.3^\circ$ , b.  $152.60^\circ \pm 0.02$ ,  $d_4^{20}$  0.99541,  $d_4^{15}$  0.98047,  $d_4^{30}$  0.96540;  $\text{AmCONH}_2$ , m.  $101.0^\circ$ , ( $\text{AmCO})_2\text{O}$ , m.  $-40.6^\circ$ ,  $b_{14.8}$   $142.9^\circ$ ,  $d_4^{20}$  0.93630,  $d_4^{15}$  0.92397,  $d_4^{30}$  0.91155; MeCOAm, m.  $-35.5^\circ$ , b.  $151.45^\circ \pm 0.02$ ,  $d_4^{20}$  0.83239,  $d_4^{15}$  0.81966,  $d_4^{30}$  0.80680;  $\text{Am}_2\text{CO}$ , m.  $14.6^\circ$ , b.  $228.0^\circ \pm 0.05$ ,  $d_4^{15}$  0.82862,  $d_4^{30}$  0.81690; MeC(NOH)Am, m.  $0.9^\circ$ ,  $b_{12}$   $99.65^\circ$ ,  $d_4^{20}$  0.90677,  $d_4^{15}$  0.89494,  $d_4^{30}$  0.88298;  $\text{Am}_2\text{CNOH}$ , m.  $-20.4^\circ$ ,  $b_{12}$   $144.2^\circ$ ,  $d_4^{20}$  0.89012,  $d_4^{15}$  0.87945,  $d_4^{30}$  0.86869; AmCOPh, m.  $24.7^\circ$ , b.  $265.2^\circ \pm 0.1$ ,  $d_4^{25}$  0.95761,  $d_4^{30}$  0.95306;  $\text{C}_6\text{H}_{11}\text{Ph}$ , m.  $-66.8^\circ$ , b.  $227.35^\circ \pm 0.1$ ,  $d_4^{20}$  0.87527,  $d_4^{15}$  0.86394,  $d_4^{30}$  0.85259.

ALBERT I. HENNE

**Catalytic oxidation of alcohol. I.** YA. KARPOV. *Zhur. Prikladnoi Khim.* 1, 121-6(1928).—EtOH was oxidized to AcH with air in the presence of oxidized Cu, Fe and Ni gauzes, and  $\text{Cr}_2\text{O}_3$ , CoO,  $\text{Mn}_2\text{O}_4$ , CuO and  $\text{BaO}_2$  deposited on asbestos.  $\text{Fe}_2\text{O}_3$ ,  $\text{Mn}_2\text{O}_4$ , CuO and  $\text{Cr}_2\text{O}_3$  were the best catalysts. With Ni and Co some C was formed. AcH was further oxidized in presence of  $\text{Ni}_2\text{O}_3$  and  $\text{CrO}_2$  to AcOH. Decompn. of AcOH into  $\text{CH}_4$  and CO was higher at higher temps. With excess of  $\text{O}_2$ , HCHO,  $\text{H}_2\text{O}$  and  $\text{CO}_2$  were formed. The time of contact is important. The use of twice the theoretical amt. of air is recommended. With  $\text{Ni}_2\text{O}_3$  the best temp is  $170-90^\circ$  and with  $\text{CrO}_2$   $170-220^\circ$ .

V. KALICHEVSKY

**Trifluorated alcohols. II. Trifluoroisopropyl alcohol.** FRÉDÉRIC SWARTS. *Bull. soc. chim. Belg.* 38, 99-109(1929).— $\text{CF}_3\text{COMe}$  is quantitatively and rapidly reduced to  $\text{CF}_3\text{CHOHMe}$  (I), by mol. H under 48 atms. in the presence of Pt black. I is obtained in an anhyd. state only by distn. from concd.  $\text{H}_2\text{SO}_4$ , which does not attack it. Its phys. consts. are: m.  $-52^\circ$ ,  $b_{14}$  (cor.)  $77.7-0.9^\circ$ ,  $d_4^{15}$  1.2799,  $n_D^{16}$  1.32021,  $n_D^{15}$  1.31720,  $n_D^{14}$  1.31613,  $n_D^{25}$  1.32253, viscosities at  $15^\circ$ ,  $25^\circ$ ,  $35^\circ$ ,  $45^\circ$  and  $55^\circ$ , 0.02590, 0.02590, 0.01714, 0.01311 and 0.00995, resp., the solubilities in  $\text{H}_2\text{O}$  at  $0.1^\circ$ ,  $18^\circ$  and  $25^\circ$  are 1 part alc. in 3.7, 4 and 4.3 parts of water, resp., the mol. cond. of a 0.1694 N soln. at  $25^\circ$  is 0.42, the ionization coeff. is  $\alpha_{25} = 1.07 \times 10^{-4}$ . The alc. group is decidedly more acid than a phenolic group and decomp. carbonates, with formation of stable alcoholates. I is extreme stable toward dehydrating agents, even at high temps.

I treated with  $\text{H}_2\text{SO}_4$  and  $\text{BaSO}_4$  gives a stable complex salt:  $\text{Ba} \left[ \text{SO}_4\text{C}_5\text{H}_4\text{F}_3 \right]_2 \cdot \text{H}_2\text{O}$ . The bromide of I cannot be obtained from I and  $\text{HBr}$ , or I and  $\text{PBr}_3$ ; in the latter case  $\text{C}_5\text{H}_4\text{F}_3\text{OPBr}_2$  (II), m.  $48^\circ$ ,  $d_4^{15}$  1.988, is formed; II reacts violently with  $\text{H}_2\text{O}$ ,  $\text{EtOH}$  or  $\text{Br}$ . The pyrolysis of the reaction product obtained from 1 mol. II and 2 atoms Br gives  $\text{CF}_3\text{CHBrMe}$  (III), b.  $49^\circ$ ,  $d_4^{15}$  1.633. I and  $\text{AcCl}$  give  $\text{CF}_3\text{CHMeOAc}$ , b.  $85.6^\circ$ ,  $d_4^{15}$  1.1823,  $n_D^{15}$  1.33021,  $n_D^{15}$  1.3314,  $n_D^{15}$  1.33520,  $n_D^{15}$  1.33806, viscosities at  $20^\circ$ ,  $30^\circ$ ,  $40^\circ$  and  $50^\circ$ , 0.00726, 0.00625, 0.00546 and 0.00480, resp. The allophanate of I, m.  $159.7^\circ$  (decompn.). ALBERT L. HENNE

**Promoter action with oxide catalysts for the decomposition of alcohols.** HOMER ADKINS AND PAUL E. MILLINGTON. *J. Am. Chem. Soc.* 51, 2449-60 (1929).—The effect upon the ratio of simultaneous reactions of alcs. of the addn. of small amts. of various acidic and basic oxides to Zn, Fe, Ti and Al oxide catalysts has been exptly. investigated. The direction of the shift in the ratio of 2 competing reactions is not dependent upon the acidity or basicity of the promoter; both the direction and amt. of change in the ratio is sp. for the alc. and the catalyst; the relative rate of competing reactions may be modified by means other than through the addn. or removal of a compd. from the catalyst. These and other facts have been considered in their bearing upon the hypotheses which have been previously advanced to account for the variation in the ratio of competing reactions over various catalysts. C. J. WEST

**Reactions of allyl alcohol over aluminum and zinc oxide catalysts.** PAUL E. WESTON AND HOMER ADKINS. *J. Am. Chem. Soc.* 51, 2430-6 (1929); cf. *C. A.* 22, 3132.— $\text{CH}_2=\text{CHCH}_2\text{OH}$  (I) is converted to  $\text{EtCHO}$  (II) over  $\text{Al}_2\text{O}_3$  at  $330^\circ$ . This conversion apparently involves an intramol. rearrangement. This is in contrast to the conversion of I to II over ZnO, which depends at least in part upon the reduction of  $\text{CH}_2=\text{CHCHO}$  (III) by a mol. of alc. The activity of  $\text{Al}_2\text{O}_3$  for the conversion of I to II was reduced by the addn. of 1%  $\text{H}_3\text{BO}_3$ ,  $\text{CrO}_3$ ,  $\text{NaOH}$  or  $\text{H}_2\text{SO}_4$ . All except the last of these materials promoted the activity of ZnO toward I. A study has been made of the effect of modifications of ZnO catalysts upon the relative amts. of III or II produced from I at  $330^\circ$ . The source of the ZnO determines its selective action toward the 2 reactions of I; e. g., ZnO from Zn oxalate gave a higher % of III than did ZnO from  $\text{Zn(OH)}_2$ . The oxide from Zn oxalate could be reproduced easily, but that from  $\text{Zn(OH)}_2$  could not. The introduction of acidic or basic substances, such as  $\text{H}_3\text{BO}_3$ ,  $\text{CrO}_3$ ,  $\text{H}_2\text{WO}_4$ ,  $\text{H}_2\text{SO}_4$  and  $\text{NaOH}$ , into the ZnO caused a selective activation toward 1 or the other of the 2 reactions, but the effect seems to be sp. for the particular substance and does not depend on its acidic or basic character. C. J. WEST

**Aliphatic hydroterpenes.** V. LONGINOV AND MILLE E. MARGOLISS. *Bull. soc. chim.* [4], 45, 156-67 (1929).—Geraniol is reduced exclusively to tetrahydrogeraniol (I) by means of Pt black in alc.; in  $\text{Et}_2\text{O}$ , some 2,6-dimethyloctane is also formed. The direct dehydration of I to 2,6-dimethyl-7-octene (II) cannot be realized. I is transformed into its bromide (III),  $b_{10}$   $91-2^\circ$ ,  $d_4^{20}$  1.0368,  $n_D^{20}$  1.4534, by  $\text{HBr}$  in sealed tubes. III heated with quinoline gives II,  $b_{738}$   $154^\circ$ ,  $d_4^{20}$  0.7396,  $n_D^{20}$  1.4212. II is transformed into 2,6-dimethyl-6-octene (IV),  $b_{753}$   $161^\circ$ ,  $d_4^{20}$  0.7473,  $n_D^{20}$  1.4272, by adding  $\text{HBr}$ , then removing it with quinoline. The structure of IV is demonstrated by oxidation with cold  $\text{KMnO}_4$ , which gives  $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{COMe}$ ; semicarbazone, m.  $155^\circ$ .

ALBERT L. HENNE

**Preparation of boric esters.** E. S. KHOTINSKII AND S. L. PUPKO. *Ukrainski Khim. Zhur.* 4, Sci. Pt., 13-8 (1929).—Boric esters are of some interest as they may serve as starting point for a series of syntheses. Fused borax is offered for the reaction of esterification, which is then thought to proceed as follows:  $3\text{Na}_2\text{B}_4\text{O}_7 + 6\text{HCl} + 15\text{EtOH} \rightarrow 6\text{NaCl} + 5\text{B(OEt)}_3 + 7\text{H}_3\text{BO}_3$ . Expts. have shown that this is a general method which can be employed in the lab. for prep. small amts. of boric esters without the aid of an autoclave. ROBERT SCHLESS

**Tertiary phosphines containing the higher alkyl radicals.** WALTER C. DAVIES, PERCY L. PEARSE AND WM. JACOB JONES. Univ. College, Cardiff. *J. Chem. Soc.* 1929, 262-8; cf. Davies and Jones, *C. A.* 23, 2150.— $\text{PCl}_3$  (12 cc.) in 50 cc.  $\text{Et}_2\text{O}$ , added to the Grignard reagent from 56 cc.  $\text{PrBr}$ , gives 10 g. tripropylphosphine,  $b_{50}$   $103.5^\circ$ ,  $b_{750}$   $187.5^\circ$ ,  $d_4^{20}$  0.807;  $\text{CS}_2$  compd., m.  $108^\circ$ ; mercurichloride, m.  $137^\circ$ . Methyltriethylphosphonium iodide, m.  $212.5^\circ$ ; tetrapropylphosphonium bromide, decomps.  $200^\circ$ .  $\text{PhPCl}_2$  (19 cc.) and the Grignard reagent from 36 cc.  $\text{PrBr}$  give 17 g. phenyldiethylphosphine,  $b_{50}$   $159^\circ$ ,  $d_4^{25}$  0.925; mercurichloride, m.  $192.5^\circ$ ; phenylmethyldiethylphosphine,

phonium iodide, m. 137°; phenyltripropylphosphonium bromide, m. 131.5°. *p*-MeC<sub>6</sub>H<sub>4</sub>PCl<sub>2</sub> (20 cc.) and the Grignard reagent from 36 cc. PrBr give 14 g. *p*-tolylidipropylphosphine, b<sub>60</sub> 174°, d<sub>4</sub><sup>25</sup> 0.921; mercurichloride, m. 129.5°; *p*-tolylmethylidipropylphosphonium iodide, m. 81.5°; *p*-tolyltripropylphosphonium bromide, m. 125.5°, hygroscopic needles, formed with difficulty. PCl<sub>3</sub> (14 cc.) and the Grignard reagent from 94 cc. iso-BuBr give 12 g. triisobutylphosphine, b<sub>60</sub> 126°; the CS<sub>2</sub> compd. forms highly unstable red crystals; mercurichloride, m. 191.5°. PhPCl<sub>2</sub> (11 cc.) and the Grignard reagent from 47 cc. iso-BuBr give 10 g. phenyldiisobutylphosphine, b<sub>60</sub> 168°, d<sub>4</sub><sup>25</sup> 0.910, mercurichloride, m. 158.5°; phenylmethylidiisobutylphosphonium iodide, m. 166.5°; *p*-MeC<sub>6</sub>H<sub>4</sub>PCl<sub>2</sub> (15 cc.) and the Grignard reagent from 47 cc. iso-BuBr give 6 g. *p*-tolylidiisobutylphosphine, b<sub>60</sub> 182.5–4.5°, d<sub>4</sub><sup>25</sup> 0.915; the HgCl<sub>2</sub> compd. could not be obtained pure; *p*-tolylmethylidiisobutylphosphonium iodide, an oil which crystallizes on long standing. PCl<sub>3</sub> (10.5 cc.) and the Grignard reagent from 78 cc. AmBr give 9 g. triamylphosphine, b<sub>60</sub> 185.5°, d<sub>4</sub><sup>25</sup> 0.820; CS<sub>2</sub> compd., m. 55°. Phenyldiamylphosphine, in 10 g. yield from 11.5 cc. PhPCl<sub>2</sub> and the Grignard reagent from 42 cc. AmBr, b<sub>60</sub> 210°, d<sub>4</sub><sup>25</sup> 0.902, only partially miscible with abs. EtOH at 15°; mercurichloride, m. 108°; phenylmethylidiamylphosphonium iodide, m. 90.5°. *p*-Tolylidiamylphosphine, b<sub>60</sub> 220°, d<sub>4</sub><sup>25</sup> 0.898; 11 g. yield from 11 cc. *p*-MeC<sub>6</sub>H<sub>4</sub>PCl<sub>2</sub> and the Grignard reagent from 51 cc. AmBr; this is less completely miscible with abs. EtOH than the Ph deriv., mercurichloride, m. 112°; *p*-tolylmethylidiamylphosphonium iodide, an oil which crystallizes on long standing. Tri-[dl-β-methylbutyl]phosphine, b<sub>10</sub> 113–7°, poor yield. Phenyl-di-[dl-β-methylbutyl]phosphine, b<sub>60</sub> 198°, d<sub>4</sub><sup>25</sup> 0.906, in 8 g. yield from 14 cc. PhPCl<sub>2</sub> and the Grignard reagent from 51 cc. of EtMeCHCH<sub>2</sub>Br; mercurichloride, m. 120°; phenylmethyl-di-[dl-β-methylbutyl]phosphonium iodide, m. 150°. *p*-Tolyl-di-[dl-β-methylbutyl]phosphine, b<sub>60</sub> 210–1°, d<sub>4</sub><sup>25</sup> 0.902, in 7 g. yield from 11 cc. *p*-MeC<sub>6</sub>H<sub>4</sub>PCl<sub>2</sub>; mercurichloride, m. 99°; *p*-tolylmethyl-di-[dl-β-methylbutyl]phosphonium iodide, m. 131°. Triisoamylphosphine, b<sub>11</sub> 131°, results in 9 g. yield from 10.5 cc. PCl<sub>3</sub> and the Grignard reagent from 78 cc. iso-AmBr, the reaction and purification being carried out in a CO<sub>2</sub> atm.; CS<sub>2</sub> compd., red, m. 79.5°; methyltriisoamylphosphonium iodide, an oil which solidifies on keeping. Phenyldiisoamylphosphine, b<sub>60</sub> 198.5°, d<sub>4</sub><sup>25</sup> 0.900, results in 10 g. yield from 14 cc. PhPCl<sub>2</sub>; mercurichloride, m. 152°; phenylmethyl-diisoamylphosphonium iodide, m. 181.5°. *p*-Tolyl-diisoamylphosphine, b<sub>60</sub> 210°, d<sub>4</sub><sup>25</sup> 0.894, mercurichloride, m. 107°; *p*-tolylmethyl-diisoamylphosphonium iodide, m. 150°. Phenyl-di-[δ-methylamyl]phosphine (phenyldiisohexylphosphine), b<sub>60</sub> 219, results in 7 g. yield from 13 cc. PhPCl<sub>2</sub>; the phenylmethyl- and ethyl-di-[δ-methylamyl]phosphonium iodides m. 146° and 115.5°, resp. *p*-Tolyl-di-[δ-methylamyl]phosphine, b<sub>60</sub> 234–5°, d<sub>4</sub><sup>25</sup> 0.888, mercurichloride, m. 110.5°; methiodide, difficult to recrystallize. No tert phosphine could be obtained when Grignard reagents from iso-PrBr and sec.-BuBr were employed

C. J. WEST

**Dichloromethylarsine.** ENRIQUE V. ZAPPI AND VENANCIO DEULOFEU. *Bull. soc. chim.* **43**, 1230–2(1928).—This compd. is obtained in 83% yield from Me<sub>2</sub>AsO<sub>2</sub>Na·3H<sub>2</sub>O and concd. HCl.

FREDERICK C. HAHN

**The yields of large-sized preparations of some organomagnesium halides.** HENRY GILMAN, EDITH L. ST. JOHN AND NINA B. ST. JOHN. *Rec. trav. chim.* **48**, 593 (1929).—The previous work of G. and his collaborators on the yields of a no. of typical organomagnesium halides under optimal conditions was carried out with about 0.05 mole of reactants. It was assumed in those studies that the yields as detd. in small runs would hold with larger preps. The present work establishes the validity of such an assumption, preps. of several typical RMgX compds. showing essentially the same yields. In general, the halide, dissolved in no more than 6 equivs. of ether, was added in 30–45 min. to commercially available Mg turnings, the reaction being completed by refluxing for 10 min. on the water bath. Then, after cooling, 5 cc. aliquots were withdrawn and titrated by the acid method of G., Wilkinson, Fisher and Meyers (cf. C. A. **17**, 530–1), the bulk of the Grignard compd. being converted into the corresponding CO<sub>2</sub>H acid by means of CO<sub>2</sub> according to the method of G. and Parker (cf. C. A. **19**, 467). The following results were obtained, the yields of the Grignard compds. as well as of the acids being given: BuBr 90%, 66%; PhCH<sub>2</sub>Cl 91%, 76%, PhBr 98%, 66%; α-C<sub>10</sub>H<sub>7</sub>Br 96%, 72%.

C. F. VAN DUIN

**Acetoxymercuric chloride.** FRANK C. WHITMORE AND G. J. LEUCK. *J. Am. Chem. Soc.* **51**, 2590–1(1929).—HgCl<sub>2</sub> and Hg(OAc)<sub>2</sub> in H<sub>2</sub>O give acetoxymercuric chloride, ClHgOAc, instead of the double salt as stated by Dimroth (*Ber.* **35**, 2044(1902)).

This salt is stable in soln. and cannot be used in place of  $\text{Hg}(\text{OAc})_2$  as a mercurating agent (negative results with  $\text{PhOH}$ ,  $p\text{-MeC}_6\text{H}_4\text{OH}$  and  $\text{PhNMe}_2$ ). C. J. WEST

**Detection of active hydrogen atoms with zinc ethyl.** F. HAURWITZ. *Mikrochemie* **7**, 88–93 (1929).— $\text{ZnEt}_2$  dissolves readily in pyridine with the evolution of heat and the formation of a yellow liquid which fumes only slightly in contact with air. This soln. forms a delicate test for the presence of active H in org. compds. in place of  $\text{MgMeI}$  as recommended by Zerevitinov (*Ber.* **40**, 2023–31 (1907)), but the test is not quant., as only 60–95% of the active H forms  $\text{C}_2\text{H}_6$ . With  $\text{BzOH}$  about 66% of the theoretical yield of  $\text{C}_2\text{H}_6$  is obtained, the remainder of the  $\text{BzOH}$  forming apparently a complex compd. with  $(\text{BzO})_2\text{Zn}$  which is unaffected by excess of the  $\text{ZnEt}_2$ . B. C. A.

**Action of hydrazine on some unsaturated acids**— $\text{C}_n\text{H}_{2n-2}\text{O}_2$ ,  $\text{C}_n\text{H}_{2n-4}\text{O}_2$ ,  $\text{C}_n\text{H}_{2n-6}\text{O}_2$ . J. HANUŠ AND J. VOŘÍŠEK. *Collection Czechoslov. Chem. Comm.* **1**, 223–7 (1929).—(Oleic acid (I) is reduced to stearic acid (II) when acted upon by  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$  at room temp. The I salt of  $\text{N}_2\text{H}_4$  is an intermediary product. When I is refluxed with the reagent, II hydrazide is obtained but II itself is formed when the K salt is so treated. Elaidic acid and a mixt. of linoleic and linolenic acids give the same products as does I. J. M. LRVINE

**Methylated crotonic nitriles.** FR. DE LAET. *Bull. soc. chim. Belg.* **38**, 163–71 (1929).— $\text{Me}_2\text{C}:\text{CHCN}$  is best prepared from iso-PrCHO, through dehydration of the cyanohydrin with  $\text{P}_2\text{O}_5$ . The yield is 50% and the purification is an easy task. A 60% yield can be obtained from  $\text{ClCH}_2\text{CO}_2\text{Et}$  and  $\text{EtMgBr}$ , through treatment of the reaction product with KCN in alc. and final dehydration over  $\text{P}_2\text{O}_5$ , but the purification is almost impossible. The phys. properties are:  $b_{757}$  141.6–0.8°,  $d_4^{20}$  0.83136,  $n_D^{20}$  1.43396,  $n_D^{20}$  1.43720,  $n_B^{20}$  1.44598,  $n_\gamma^{20}$  1.45367. The nitrile is easily transformed into its amide, m. 107–8°, by digestion in 66%  $\text{H}_2\text{SO}_4$ .  $\alpha,\beta$ -Dimethylcrotonic nitrile is obtained from iso-PrCOMe, through dehydration of the cyanohydrin,  $b_{11}$  89°. Its phys. consts. are:  $b_{766}$  157.0–0.4°,  $d_4^{20}$  0.84321,  $n_\alpha^{20}$  1.44223,  $n_D^{20}$  1.44554,  $n_B^{20}$  1.45395,  $n_\gamma^{20}$  1.46117. Its amide, m. 130.5°, is obtained by digestion in concd.  $\text{H}_2\text{SO}_4$ . It was impossible to prep.  $\text{Me}_2\text{C}:\text{CHCN}$  from iso-PrCOEt by a similar method, because the dehydration of the cyanohydrin regenerates the original ketone. ALBERT HENNE

**Butenoic esters.** P. BRUYLANTS. *Bull. soc. chim. Belg.* **38**, 133–45 (1929).—Et vinylacetate (I) is best prepared from 1 mol. of the acid, 3 mols. of abs. EtOH and 15 cc. concd.  $\text{H}_2\text{SO}_4$ . Its phys. consts. are:  $b_{755}$  124.0–0.2°,  $d_4^{20}$  0.91224,  $n_\alpha^{20}$  1.40777,  $n_D^{20}$  1.41054,  $n_B^{20}$  1.41651,  $n_\gamma^{20}$  1.42154; its isomerization with NaOPh gives exclusively Et crotonate (II). The best method of prepn. of II is similar to that of I. Phys. consts. of II are:  $b_{748}$  136.6–0.8°,  $d_4^{20}$  0.91752,  $n_\alpha^{20}$  1.42196,  $n_D^{20}$  1.42524,  $n_B^{20}$  1.43266,  $n_\gamma^{20}$  1.43911. Et isocrotonate is best prepd. as I and II: it  $b_{749}$  125.5–6.0°,  $d_4^{20}$  0.91820,  $n_\alpha^{20}$  1.42124,  $n_D^{20}$  1.42423,  $n_B^{20}$  1.43137,  $n_\gamma^{20}$  1.43774. Et methylacrylate is best prepd. from Et  $\beta$ -chloroisobutyrate and pyridine in the presence of KI; it must be redistd. *in vacuo* on Ag powder to be absolutely pure, and will only then become stable:  $b_{88}$  56.6°,  $d_4^{20}$  0.91063,  $n_\alpha^{20}$  1.41179,  $n_D^{20}$  1.41472,  $n_B^{20}$  1.42111,  $n_\gamma^{20}$  1.42656. It can also be obtained from Et  $\alpha$  bromoisobutyrate and  $\text{PhNEt}_2$ , but is less easily purified. Et trimethyleneformate,  $\text{CH}_2\text{CH}_2\text{CHCO}_2\text{Et}$ , obtained as I,  $b_{750}$  132.4–0.6°,  $d_4^{20}$  0.96078,  $n_\alpha^{20}$  1.41640,  $n_D^{20}$  1.41902,

$n_B^{20}$  1.42426,  $n_\gamma^{20}$  1.42897.  $\text{CH}_2\text{CH}_2\text{CHCO}_2\text{H}$ ,  $d_4^{20}$  1.0885,  $n_\alpha^{20}$  1.43639,  $n_\gamma^{20}$  1.43901,  $n_B^{20}$  1.44529,  $n_D^{20}$  1.45051.  $\text{CH}_2\text{CH}_2\text{CHCN}$ ,  $d_4^{20}$  0.89461,  $n_\alpha^{20}$  1.42044,  $n_D^{20}$  1.42293,  $n_B^{20}$  1.42880,  $n_\gamma^{20}$  1.43355. ALBERT L. HENNE

**The preparation of phosphoacetic ester.** A. F. ARBUZOV AND G. KH. KAMAI. *J. Russ. Phys.-Chem. Soc.* **61**, 619–22 (1929).—Et phosphoacetate (I) was first prepd. by Arbuzov and Dunin (cf. *C. A.* **8**, 2551) by the action of  $\text{BrCH}_2\text{CO}_2\text{Et}$  on Et phosphide. Nylen (cf. *C. A.* **18**, 3167) obtained I in 50% yield by the action of halogen-substd.  $\text{AcOEt}$  on  $\text{NaEt}_2\text{PO}_3$  (II). The present study was undertaken to devise a method giving a larger yield of I. The reaction-solvent and the coagulation of the colloidal NaCl formed were found to be of great importance.  $\text{Et}_2\text{HPO}_3$  (III) prepd. by the usual method (cf. *Chem. Zentr.* **1906**, **II**, 749) was added dropwise to NaOEt, giving

**II**, which with  $\text{ClCH}_2\text{CO}_2\text{Et}$  gives **I** and  $\text{NaCl}$ . Yields of **I**: with ligroin as solvent, 56%; with  $\text{Et}_2\text{O}$ , 59.5%; with abs.  $\text{EtOH}$ , 94.6%. These yields were obtained only when the  $\text{NaCl}$  was rendered cryst. by addn. of 2-3 cc.  $\text{H}_2\text{O}$  to the reaction mixt. Coagulation of the  $\text{NaCl}$  by boiling with activated charcoal gave lower yields.

LEWIS W. BUTZ

**Syntheses with phosphoacetic ester.** A. E. ARBUZOV AND A. I. RAZUMOV. *J. Russ. Phys.-Chem. Soc.* **61**, 623-8(1929); cf. *C. A.* **20**, 2928; **21**, 1627; and refs. in preceding abstr.—Earlier attempts to prep. higher homologs of phosphoacetic acid were either unsuccessful or resulted in small yields. These should be useful in synthetic work since the H is easily replaced by Na and K, giving derivs. that react with halogen compds. by splitting out metallic halide. The present paper concerns itself with the interaction of  $\text{MeI}$  and of  $\text{PhCH}_2\text{Cl}$  (**I**) with the Na and K derivs. of phosphoacetic ester (**II**).  $\text{MeI}$  with **II** (Na deriv.) gave only 40.5% of the expected *tri-Et*  $\alpha$ -phosphopropionate,  $(\text{EtO})_2\text{POCHMcCO}_2\text{Et}$  (**III**), and only 50%  $\text{NaI}$ .  $\text{EtI}$  and the acid ester of  $\alpha$ -phosphopropionic acid (*mono-Na salt*) (**IV**) were formed as by-products.  $\text{MeI}$  and the K deriv. of **II** gave **III** in 85% yield. It is suggested that the Na deriv. of **II** exists in 2 tautomeric forms. The reactions with **I** were more difficult to study, since **I** reacts much less easily than  $\text{MeI}$ , and the org. product is less readily sepd. from the metallic halide. Sapon. of **III**,  $b_p$  126.5-7°, as well as of the free di-Et ester obtained from **IV**, by heating in sealed tubes with  $\text{HCl}$ , gives white, hygroscopic  $\alpha$ -phosphopropionic acid,  $(\text{HO})_2\text{POCHMcCO}_2\text{H}$  (**V**), m. 119-32°, sol. in  $\text{H}_2\text{O}$ ,  $\text{EtOH}$ , and other org. solvents. Salts of **V**, prepd. from **V** and metallic carbonates, could not be crystd. With **I** it was necessary to heat the mixt. throughout the reaction, and only the K deriv. of **II** gave a weighable yield of *benzylphosphoacetic ester* (**VI**). **VI** was obtained in 22% yield by heating the mixt. 5-6 hrs. on the  $\text{H}_2\text{O}$  bath, as a colorless liquid,  $b_p$  180-0.5°,  $d_4$  1.1349. Sapon. of **VI** gave white, extremely hygroscopic *benzylphosphoacetic acid*,  $(\text{OH})_2\text{POCH}(\text{PhCH}_2)\text{CO}_2\text{H}$ , m. 137-45°, sol. in  $\text{H}_2\text{O}$ ,  $\text{EtOH}$ , petroleum ether, and other org. solvents.

LEWIS W. BUTZ

**Interaction of bromine with acetic anhydride.** V. Bromination and chlorination compared. Some properties of acetic chloroacetic anhydride. HERBERT BEN WALSON AND CECIL EDWARD GREGORY. *J. Chem. Soc.* **1929**, 1373-5; cf. *C. A.* **23**, 819.  $\text{ClCH}_2\text{CO}_2\text{Ac}$ , on heating, decomps. into mol. quantities of  $\text{Ac}_2\text{O}$  and  $(\text{ClCH}_2\text{CO})_2\text{O}$ , refluxed with a mol. proportion of  $\text{ClCH}_2\text{CO}_2\text{H}$ ,  $\text{AcOH}$  and  $(\text{ClCH}_2\text{CO})_2\text{O}$  are formed.  $\text{HCl}$  gives  $\text{AcCl}$  and  $\text{ClCH}_2\text{CO}_2\text{H}$ . Refluxing 120 g.  $\text{AcOH}$  and 225 g.  $\text{ClCH}_2\text{COCl}$  at 100° gives  $\text{HCl}$  (loss in wt., 60 g.), a fraction of 50 g. of  $\text{AcCl}$ , 30 g., b. 54-150°, giving some  $\text{AcCl}$  and  $\text{Ac}_2\text{O}$  but principally  $\text{AcOH}$ , 70 g. b. 150-200°, giving some  $\text{AcOH}$  and a mixt. of  $\text{ClCH}_2\text{CO}_2\text{H}$  and its anhydride, m. 38-47°, and 135 g.  $(\text{ClCH}_2\text{CO})_2\text{O}$ . If, after removing the  $\text{AcCl}$ , the remaining mixt. is distd. at 20 mm., a fraction b. 80-5°, consisting mainly of  $\text{ClCH}_2\text{CO}_2\text{Ac}$ , is obtained. The scheme previously put forward to represent the halogenation of  $\text{AcOH}$  is thus completely confirmed, with the single modification that the reaction  $\text{XCH}_2\text{COX} + \text{AcOH} \rightleftharpoons \text{AcX} + \text{XCH}_2\text{CO}_2\text{H}$  may be written in 2 stages:  $\text{XCH}_2\text{COX} + \text{AcOH} \rightleftharpoons \text{XCH}_2\text{CO}_2\text{Ac} + \text{HX}$ ;  $\text{XCH}_2\text{CO}_2\text{Ac} + \text{HX} \rightleftharpoons \text{XCH}_2\text{CO}_2\text{H} + \text{AcX}$ ; for the exptl. results lead inevitably to the conclusion that the halogen reacts with the acyl halide, the monohalogenated acid being formed as the result of a reaction between the acid and the substituted halide.

C. J. WEST

**The glycol industry.** HANS SCHRADER. *Z. angew. Chem.* **42**, 541-6(1929).—The technical methods of prepn. are given for ethylene glycol, ethylene oxide, propylene oxide, 1,4-dioxan and the esters, ethers and amines of both glycols. Diethylene glycol is also described. Statistics on production and factors affecting the price are discussed.

J. G. McNALLY

**Tetramethylene glycol and tetramethylene chlorohydrin.** W. R. KIRNER AND G. HOLMES RICHTER. *J. Am. Chem. Soc.* **51**, 2503-6(1929).—The following synthesis was based on the work of Bennett (*C. A.* **19**, 2640) and B. and Hock (*C. A.* **21**, 1639). The following steps were involved (yields are given, the over-all yield being 11%):  $\text{PhCH}_2\text{Cl} + \text{NaOCH}_2\text{CH}_2\text{OH} \rightarrow \text{PhCH}_2\text{OCH}_2\text{CH}_2\text{OH}$  (65%)  $\rightarrow (\text{SOCl}_2 + \text{C}_6\text{H}_5\text{N}) \text{PhCH}_2\text{OCH}_2\text{CH}_2\text{Cl}$  (86%)  $\rightarrow (\text{Na} + \text{CH}_2(\text{CO}_2\text{Et})_2) \text{PhCH}_2\text{OCH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{Et})_2$  (75%)  $\rightarrow$  (hydrolysis)  $\text{PhCH}_2\text{O}(\text{CH}_2)_2\text{CO}_2\text{H}$  (97%)  $\rightarrow (\text{EtOH} + \text{H}_2\text{SO}_4) \text{PhCH}_2\text{O}(\text{CH}_2)_2\text{CO}_2\text{Et}$  (77%)  $\rightarrow (\text{Na} + \text{EtOH}) \text{PhCH}_2\text{O}(\text{CH}_2)_2\text{OH}$  (45-55%)  $\rightarrow (\text{HBr}/\text{HO}(\text{CH}_2)_2\text{OH})$  (70%). Muller's method (*C. A.* **22**, 3391), involving the reduction of di-Et succinate, appears to be cheaper, simpler and more rapid. The glycol in  $\text{C}_6\text{H}_5\text{N}$  and  $\text{SOCl}_2$  give 47% of  $\text{HO}(\text{CH}_2)_4\text{Cl}$ ,  $b_p$  84-5°,  $d_4^{20}$  1.0883,  $n_D^{20}$  1.4518; *phenylurethan*, m. 54°;  $\alpha$ -naphthylurethan, m. 69-70°.

C. J. WEST

**Determination of the configuration of polyalcohols by means of boric acid.** J. BÖRSEKEN. *Bull. soc. chim. Belg.* 37, 385–402 (1928).—A lecture. H. L. D.

**Several syntheses of bromomethiononic acid.** H. J. BACKER. *Rec. trav. chim.* 48, 616–21 (1929).—Bromomethiononic acid can be prepd. as follows: (1) by sulfonation of  $\text{CH}_2\text{BrCO}_2\text{H}$  or  $\text{HO}_2\text{SCHBrCO}_2\text{H}$  (cf. Backer, *C. A.* 20, 900); (2) by hydrolysis of  $\text{HCOCBr}(\text{SO}_3\text{H})_2$  with alkali; (3) by bromination of  $\text{CH}_2(\text{SO}_3\text{H})_2$ ; (4) by decompn. of  $\text{N}_2\text{C}(\text{SO}_3\text{H})_2$  with  $\text{HBr}$ ; (5) by interaction of  $\text{Br}_2\text{CHSO}_3\text{K}$  with  $\text{K}_2\text{SO}_3$ . Methods (2), (3), (4) and (5) are described in this paper, method (2) giving the best results. The hydrolysis of  $\text{HCOCBr}(\text{SO}_3\text{H})_2$  was carried out by heating 37.7 g. of the K salt of the acid (cf. Backer, *C. A.* 23, 3209), 30 cc. water and 20 cc. 5 *N* KOH until everything has passed into soln.; after cooling down the normal K salt is obtained in 86% yield by the addn. of 50 cc. alc. On recrystn. from water this K salt may be obtained without or with 1 mole of water of crystn.; at 25° 100 g. water dissolves 40.8 g. of the anhyd. salt  $\text{BrCH}(\text{SO}_3\text{H})_2$  easily gives a normal strychnine salt, which is difficultly sol. in water and may be used for the purification of the acid as well as for the prepn. of the free acid and other salts; it contains 3  $\text{H}_2\text{O}$ . The following salts were prepd. in the usual way: normal Ba, contg. 4 or 4.5  $\text{H}_2\text{O}$ ; normal Na, contg. 2  $\text{H}_2\text{O}$ , monoclinic crystals with the following properties:  $a:b:c = 0.9719:1:10.9457$ ,  $\beta = 71.56'$ , observed forms,  $a(100)$ ,  $q(110)$ ,  $o(111)$ ,  $r(011)$ ,  $\omega(\bar{1}11)$ ,  $c(001)$ ; normal Ti, anhyd.; monoclinic crystals;  $a:b:c = 1.3572:1:1.8728$ ,  $\beta = 70.27'$ , observed forms,  $a(100)$ ,  $\omega(111)$ ,  $p(101)$ ,  $c(001)$ ,  $o(111)$ ; 100 g. of water dissolves at 25° 16.7 g. of the anhyd. Ti and 22.80 g. of the anhyd. Ba salt. From the latter was prepd. the free acid, which contains 211.0 and m. 125–6°. The bromination of  $\text{CH}_2(\text{SO}_3\text{H})_2$  was carried out by heating 0.05 mole of the acid, 10 g. water, 9 g. Br and 5 cc. of a satd. HBr soln. during 5 hrs. at 250°; yield 25% after purification by means of the Ba salt. In order to convert  $\text{N}_2\text{C}(\text{SO}_3\text{H})_2$ , prepd. according to v. Pechmann and Manck (*Ber.* 28, 2377 (1895)) into  $\text{BrCH}(\text{SO}_3\text{H})_2$ , 14.8 g. was brought into 40 cc. concd. HBr at 0°; yield 70% after purification by means of the strychnine salt. The interaction of  $\text{BrCHSO}_3\text{K}$  (Backer, *C. A.* 21, 2871) with  $\text{K}_2\text{SO}_3$  is not suitable for the prepn. of  $\text{BrCH}(\text{SO}_3\text{H})_2$ , reduction taking place simultaneously with formation of  $\text{CH}_2(\text{SO}_3\text{H})_2$ . C. F. VAN DUIN

**Partial esterification of polyhydric alcohols. VIII. Proposed standards of reference in work on the configuration of glycerol derivatives.** ARTHUR FAIRBOURNE. King's College, London. *J. Chem. Soc.* 1929, 1151–3; cf. *C. A.* 23, 2152.—Hibbert, Whelen and Carter (*C. A.* 23, 818) state that all 5 of the possible glycerol Me ethers have been isolated:  $\alpha$ - and  $\beta$ -mono-Me;  $\alpha,\beta$ - and  $\alpha,\gamma$ -di-Me and  $\alpha,\beta,\gamma$ -tri-Me. It is now shown that the  $\alpha,\beta$ -di-Me ether of Gilchrist and Purves (*C. A.* 20, 376) is identical with the  $\alpha,\gamma$ -di-Me ether of Zunino (*Atti accad. Lincei* 6, 348 (1897)), both yielding the same *p*-nitrobenzoyloxydimethylmethoxypropane, m. 43°. One di-Me ether, therefore, is still unknown, and the structure of the known ether is still unproved. C. J. W.

**Note on the paper, "Configuration of Pentaerythritol," by Böresken and Felix.** A. SEMENTZOV. *Ber.* 62B, 514 (1929); cf. *C. A.* 22, 2367.—A theoretical discussion of the steric configuration of the C atom on the basis of the results of B. and F. E. K.

**Biochemistry of sulfur. III. Chemical groups involved in the naphthoquinone reaction for cysteine and cystine.** M. X. SULLIVAN AND W. C. HESS. *U. S. Pub. Health Repts.* 44, 1599–1608 (1929); cf. *C. A.* 20, 2686; 23, 3941.—S. and H. give the method of prepn., a modification of Hofmann's potash fusion of a thiazole, of *o*-aminophenyl mercaptan, and its disulfide  $(\text{H}_2\text{NC}_6\text{H}_4)_2\text{S}_2$  and cystine-amine. Since aminothiophenol is negative and especially since cystine-amine  $(\text{H}_2\text{NCH}_2\text{CH}_2)_2\text{S}_2$  fails to give the typical reaction given by cystine it would seem that, for the Sullivan cystine reaction, 3 nonsubstituted groups are necessary, the (SH),  $(\text{NH}_2)$  and  $(\text{CO}_2\text{H})$  groups, and that it is given (A) only by cystine  $\text{HSCH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$  or cystine  $[\text{HO}_2\text{CCH}(\text{NH}_2)\text{CH}_2]_2\text{S}_2$  after reduction or (B) by compds. of the same configuration of the aliphatic series. Insofar as is known, cysteine and cystine, free or combined, are the only compds. of this nature occurring in vegetable or animal tissue or exts. thereof. It is planned to test out the effect of lengthening the C chain and thus sepg. the reacting groups and to test the reaction of isomers such as isocysteine and isocystine. J. A. KENNEDY

**Methylation of *dl*-glyceraldehyde.** H. GORDON REEVES. *J. Chem. Soc.* 1929, 1327–9.—Methylation, hydrolysis and reduction should distinguish between the 2 possible structures,  $\text{HOCH}(\text{CH}_2\text{OH})\text{O}$  and  $\text{HOCH}(\text{CH}(\text{OH})\text{CH}_2\text{O})$ , since the

1st should give  $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OMe}$  and the 2nd,  $\text{MeOCH}(\text{CH}_2\text{OH})_2$ . However, it has not been possible to obtain a completely methylated deriv.  $\text{Me}_3\text{SO}_4$  and  $\text{NaOH}$ , at increasing temps. up to 100°, gave 10% of a pale yellow oil, which did not reduce

Fehling soln. and in which MeI and Ag<sub>2</sub>O did not increase the MeO content; the formula suggested is:  $\text{O} \cdot \text{CH}(\text{CH}_2\text{OH}) \cdot \text{CH}(\text{OMe}) \cdot \text{O} \cdot \text{CH}(\text{CH}_2\text{OH}) \cdot \text{CHOMe}$ . Heating the

aldehyde in MeOH at 100° for 24 hrs. gives a non-reducing brown oil, with 22.3% MeO, which could not be methylated further. Shaking the aldehyde in MeOH (100 cc. contg. 4 g. HCl) for 24 hrs. gives a *mono-Me deriv.*, m. 204.5° (av. yield of 10 expts., 5%), which does not reduce Fehling or Benedict soln. even when hot; Fischer and Taube (C. A. 22, 223) obtained a bimol. Me cycloacetal, m. 158.5–9.5°, from the di-Ac deriv.

C. J. WEST  
**Dioximes. LII.** G. B. SEMERIA AND B. SOMIGLIANA. *Gazz. chim. ital.* 59, 258 (5 (1929); cf. C. A. 23, 754, and Ponzio and Melone, C. A. 23, 3665.—The conclusions reached by Ölander in his work on the kinetics of formation of Me<sub>2</sub>CNOH (I) (cf. C. A. 22, 344) induced S. and S. to study the influence of the *p*<sub>H</sub> value on the reaction in which oximes of compds. contg. an oximino group are formed, i. e., where dioximes are formed from so-called isonitroso ketones of the form R'CO(:NOH)R". MeCOC(:NOH)H (II) was chosen because it is sol. in water and forms on oximation a dioxime MeC(:NOH)C(:NOH)H (III) which exists in but 1 form which is sol. in water. Since it was impossible to det. rapidly II and III, the method used by Ölander was used, i. e., detg. iodometrically the NH<sub>2</sub>OH (IV) consumed in very dil. solns. of *p*<sub>H</sub> 7.4, in which the iodohydroxylamine equiv. was kept const. The exptl. results show that in solns. of an acidity from *p*<sub>H</sub> 1.2 to 12.0, the formation of III from II, thus: II + IV → III + H<sub>2</sub>O, is not satisfied by the simple formula of bimol. reactions; in fact, by calcg. the reaction velocity const. K for each acidity by the formula  $K = (T - T_n) / (CT_n(t_n - t))$ , for various titers (T) and corresponding times (t) the values obtained differ even more than 1 unit in the 1st significant figure. Nor is the relation of Ölander for the formation of I from AcMe (which would agree with the simple relation above for the reaction in solns. with *p*<sub>H</sub> 5–8) applicable. Moreover, unlike I, the formation of which is rapid at *p*<sub>H</sub> 5–8, is slower at higher *p*<sub>H</sub> values, and is rapid again in strongly basic solns., the formation of III increases with increase in *p*<sub>H</sub>. The hypothesis of Ölander that the intermediate compd. Me<sub>2</sub>C(NHOH)OH is formed may apply in the present case, where the compd. would be Me(HO)C(NHOH)C(:NOH)H. But the increase in velocity of the reaction with increase in *p*<sub>H</sub> can be explained only by the fact that II, whose structure in soln. is MeCOC(:NOH)H, is gradually transformed (as the soln. becomes more basic) to a yellow salt in which both carboxyl and metal have secondary valences. On the other hand a study of the absorption spectra of isonitroso ketones led Baly, Marsden and Stewart to the conclusion (cf. *J. Chem. Soc.* 89, 966(1906)) that they behave as cyclic non-carbonylic compds., thus:  $\text{R} \cdot \text{C} : \text{CR}'' \cdot \text{N}(\text{OH}) \cdot \text{O}$ , which as salts in soln. are in equil. thus:  $\text{R}'\text{NaC}(\text{N}(\text{O})\text{C}(\text{O})\text{R}''$

$\rightleftharpoons \text{R}'(\text{NaON})\text{CC}(\text{O})\text{R}''$ . The expts. of S. and S., which are based on entirely different concepts, are not at variance with these ideas if the equil.:

is displaceable toward the right with increase in *p*<sub>H</sub>. Solns. with *p*<sub>H</sub> values of 4.6–9 were prepd. by mixing 1/15 mol. Na<sub>2</sub>HPO<sub>4</sub> with 1/15 mol. KH<sub>2</sub>PO<sub>4</sub>, those with *p*<sub>H</sub> above 9 from 0.1 N NaOH with 0.05 mol. Na<sub>2</sub>HPO<sub>4</sub>, those with *p*<sub>H</sub> 3 from 0.1 N HCl and 0.1 mol. Na citrate, and those with *p*<sub>H</sub> below 3 from 0.1 N KCl. With these solns. there was no change in acidity. Detns. of *p*<sub>H</sub> were made by the Hellige method, instead of the electrometric method, because of the rapidity necessary and because the H and quinhydrone electrodes were impossible for chem. reasons. Five cc. of 0.1 M II soln. and 5 cc. of 0.1 M HONH<sub>2</sub>Cl soln. at 20° were added with const. agitation to 500 cc. of *p*<sub>H</sub> soln. at 20°, 5-cc. samples were withdrawn periodically during 2 hrs., and by addn. of suitable NaOH, HCl, Na<sub>2</sub>HPO<sub>4</sub>, or KH<sub>2</sub>PO<sub>4</sub> solns. the *p*<sub>H</sub> of 7.4 was reached in the shortest possible time. Five cc. of I soln. were then added immediately and the soln. titrated with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. The II used in the expts. was crystd. from very dil. solns. in CCl<sub>4</sub>, in which case it m. 68–9°. Unlike the product from other solvents, it does not then alter with time. The results, which are given in tabular and graphical

$\text{PhC:N.O.N(:O):CH}$  and  $\text{PhC:N(:O).O.N:CH}$  are the same compd., *i. e.*, an impure

Ph peroxide arising from impure reagents; (2) hydrogenation of  $\alpha\text{-PhC(:NOH)C(:NOH)H}$  (I) with  $\text{N}_2\text{O}_4$  gives a compd. (m.  $112^\circ$ ) which is quite different from its isomer (m.  $108^\circ$ ) prepd. from  $\beta\text{-PhC(:NOH)C(:NOH)H}$  (II) by 4 *N*  $\text{HNO}_3$ ; (3) the compd.  $\text{PhC:N.O.N:COH}$  does not exist (cf. Scholl, *Ber.* 23, 3503(1890)); (4)  $\text{PCl}_5$  with the

peroxide of Wieland and Semper (cf. *C. A.* 2, 1012) (from I) does not form  $\text{PhC:N.O.N:CH}$  (III) but  $\text{ClC:N.O.CPh:N}$ , and (5) neither of the 2 products of

the dehydrogenation of I and II can have the structure  $\text{PhC:N.O.N(:O):CH}$  (IV) or

$\text{PhC:N(:O).O.N:CH}$  (V), *i. e.*, cannot be furoxans. Reasons have already been given

(cf. Ponzio and Avogadro, *C. A.* 21, 1976) why the deriv. of I is  $\text{PhC(:NOH)C:N:O}$  (VI) and that from II is  $\text{PhC:N.O.O.N:CH}$  (VII). To these reasons should be added

that while the asym. azoxy derivs.  $\text{R'N(:O):NR''}$  can both be reduced to  $\text{R'-N-NR''}$  derivs. (cf. *Rend. accad. Lincei* 21, I, 155(1912)), only VI can be reduced by  $\text{SnCl}_2$  to III. VII with no extranuclear O is stable toward  $\text{SnCl}_2$ . To this discussion is now added a new exptl. proof, which is based on purely phys. data. Conforming to the idea of Bruni (cf. *Sammlung Chemisch-technischer Vorträge* 6, 415(1901)) that the formation of solid solns. (and resulting cryometric abnormalities) depend upon similar structures of solute and solvent, VI and VII should show normal wts. in III, and by analogy  $p\text{-MeC}_6\text{H}_4\text{C(:NOH)C:N:O}$  (cf. Avogadro, *C. A.* 18, 1491) and  $p\text{-MeC}_6\text{H}_4\text{C:N.O.O.N:CH}$  (cf. Ponzio and Avogadro, *C. A.* 21, 1976) should show

normal wts. in  $p\text{-MeC}_6\text{H}_4\text{C:N.O.N:CH}$  (VIII), whereas IV and V and the furoxans

$\text{MeC}_6\text{H}_4\text{C:N(:O).O.N:CH}$  and  $\text{MeC}_6\text{H}_4\text{C:N.O.N(:O):CH}$  should form solid solns.

with the corresponding furazans (III and VIII), which should show abnormal mol. wts. Since the compds. of the 2 series are all solids, since they melt without decompn. at relatively low temps. and since they can readily be obtained in a pure state, it was to be expected that very precise phys. measurements could be made. Cryometric measurements of the mol. wts. of the dehydrogenation products of I, of II and of  $p\text{-MeC}_6\text{H}_4\text{C(:NOH)C(:NOH)H}$  (IX), each in III and in VIII, were made. In all cases normal mol wts were found, *i. e.*, no solid solns. were formed, and therefore the presence in the dehydrogenation products of a penta-atomic furazanic ring is excluded. Consequently, as already shown by chem. reactions, the dehydrogenation products of I, II and IX are not furoxans.

C. C. DAVIS

**Condensation of acetaldehyde with methylmalonic ester. Methylations with methyl bromide.** HOWARD J. LUCAS AND WM. G. YOUNG. *J. Am. Chem. Soc.* 51, 2535-8(1929).— $\text{MeBr}$  may satisfactorily replace  $\text{MeI}$  in the prepn. of the Me derivs. of  $\text{CH}_2(\text{CO}_2\text{Et})_2$  and  $\text{AcCH}_2\text{CO}_2\text{Et}$ . An app. is described for carrying out the prepn. of the  $\text{MeBr}$  and the bromination in 1 step. Heating  $\text{MeCH}(\text{CO}_2\text{Et})_2$ ,  $\text{AcH}$  and  $\text{Ac}_2\text{O}$  at  $140^\circ$  for 50 hrs. gives 63% of *di-Et 3-hydroxybutane-2,2-dicarboxylate*,  $b_{3-6}$   $100\text{--}6^\circ$ ,  $d_4^{21}$  1.0732; *diamide*, m.  $209.5^\circ$  (cor., decompn.). The ester could not be sapon. by alc.  $\text{KOH}$  to the acid.

C. J. WEST

**Walden inversion.** II. HANS N. K. RØRDAM. *J. Chem. Soc.* 1929, 1282-90; cf. *C. A.* 23, 101.—R. has proposed a new hypothesis of the reaction mechanism of the Walden inversion, the fundamental assumption being that the optically active mol., after splitting off 1 of the radicals linked to the asym. C atom, oscillates between 2 configurations, each of which, by the addn. of a new radical, will produce only 1 of the 2 possible optical antipodes. From the point of view of this hypothesis 2 distinct types of inversions are postulated, depending upon the character of the non-asym. component in the reaction: (I) Reactions where the splitting of the optically active mol. either occurs spontaneously or is caused by some mol. which is neither identical with nor contains the entering radical; in this type both *d*- and *l*-forms are produced in amts. which depend upon the concns. (II) Reactions where the splitting of the optically active mol. is brought about by a mol. contg. the radical which displaces the ejected radical. Reactions must also be expected which represent a transition stage between the 2 types, or which actually proceed simultaneously in the 2 different

typical ways. In this paper a reaction of type I has been chosen in order to investigate the influence upon it of systematic variation of the concns., the ionic strength (and consequently the activity factor  $F$ ) being kept const. and of the ionic strength, the concn. being kept const. *l*-Bromosuccinic acid and K xanthogenate were used. The results are given in tables and curves.

**Identity of the two possible isomeric methyl ethyl  $\beta$ -methyl- $\alpha$ , $\gamma$ -dicyanoglutaconates.** Y. URUSHIBARA. *Bull. Chem. Soc. (Japan)* 3, 261-5(1928); cf. *C. A.* 22, 2551.—Proof of the identity of the Na compds. obtained by either condensation (*C. A.* 23, 375) is obtained by converting each specimen into the cryst. Ag deriv. by the action of aq. AgNO<sub>3</sub> and examn. of their  $n$ . X-ray spectra of both specimens obtained by the Debye-Scherrer method with the  $K\alpha$  Mo line are identical, the most intense line corresponding with a lattice distance 3.56 Å. U. Either specimen, or one obtained by mixed crystn. of the 2, gives the same  $n$ 's, elongation occurring in the direction of the optical elasticity axis  $X$ ,  $n_1$  (the  $n$  for the faster wave) being equal to  $\alpha$ , the value of  $\alpha_D^{27}$  being  $1.503 \pm 0.001$ , and the zone of elongation being neg. Similar results were obtained with the Ag deriv. of di-Me  $\beta$ -methyl- $\alpha$ , $\gamma$ -dicyanoglutaconate, while the Ag deriv. of the di-Et ester elongates in the direction of the optical elasticity axis  $Z$ , the zone being pos. and  $\alpha_D^{27}$  1.580. The results do not decide between the constitutions  $C(CN)(CO_2Et):CMcNa(CN)CO_2Me$  and  $C(CN)(CO_2Me):CMcNa(CN)CO_2Et$ , but the fact that the presence of a  $\beta$ -Me group causes no change in the course of the condensation favors the mechanism given previously (*loc. cit.*). Me ethoxyethylideneacyanacetate, m. 76-7°, is described.

B. C. A.

**Existence of liquid racemates.** ALAN N. CAMPBELL. Univ. of Aberdeen *J. Chem. Soc.* 1929, 1111-23.—From an examn. of the phys. consts., the conclusion is irresistible that in the case of the liquid esters of tartaric acid there is a marked difference in the chem. nature of the active and inactive forms. As the series of esters is ascended from the Et to the Am members, the difference in the degree of assocn. decreases, at room temp., so that Am tartrate appears to be but little more assocd. than its *dl*-form. As the temp. rises, the active form dissociates more than the *dl*-form, so that Bu racemate has become identical with its active form. At the same time it must be supposed that sometimes the racemate (which must also be assocd. to some extent) dissociates at a different rate from the active form, for, e. g., the order of viscosities of iso-Pr *d*- and *dl*-tartrate is reversed at 40°, whereas the viscosities of the Am esters, almost identical at 18°, show a considerable difference at 40°; at 80° the consts. are still closer. *Pr racemate*, m. 25°,  $b_{11}$  167°,  $b_{765}$  286°,  $d_4^{20}$  1.1256 (values are also given for 18°, 40°, 60° and 80°),  $\eta$  1.4861, 0.2965, 0.0461 at 18°, 40° and 80°, resp.,  $n_D$  1.4413,  $n_F$  1.4523 at 18°,  $\gamma$  27.32, 25.32 at 40° and 80°, resp., *iso-Pr ester*, m. 34°,  $b_{12}$  154°,  $b_{765}$  275°,  $d_4^{20}$  1.1166 (values also at 18°, 40°, 60° and 80°),  $\eta$  5.8243, 0.6150, 0.0647 at 18°, 40° and 80°, resp.,  $n_D$  1.4374,  $n_F$  1.4461 at 18°,  $\gamma$  26.58, 25.70 at 40° and 80°, resp., *Bu ester*,  $b_{12}$  185°,  $b_{765}$  320°,  $d_4^{18}$  1.0879 (values are also given for 15°, 40° and 80°),  $\eta$  0.9455, 0.2475 and 0.0445 at 18°, 40° and 80°, resp.,  $n_D$  1.4451,  $n_F$  1.4568 at 18°,  $\gamma$  28.36 and 26.17 at 40° and 80°, resp. *Isobutyl ester*, m. 58°,  $b_{13}$  195°,  $b_{765}$  311°,  $d_4^{20}$  1.0160,  $d_4^{100}$  1.0124,  $\eta$  0.0595 at 80°,  $\gamma$  24.79 at 80°. The original should be consulted for the other phys. data collected from the literature or detd. by C. on the Et, Pr, iso-Pr, Bu, iso-Bu and Am tartrates and racemates on the m. p., b. p., d. and coeff. of expansion, viscosities, refractivities and dispersions, surface tension, and sp. rotations. The f. p. curve of mixts. of iso-Bu *d*- and *l*-tartrates is given; the eutectic is at 53.4° with 32.8% of the *l*-ester. The soly. of these esters in EtOH is reported for 0°, 18° and 25°, resp.

C. J. WEST

**The velocity of cyclic transformation of 1,4-diketones.** I. A. TREFIL'EV AND RAZUMOV. *Ukrainskii Khim. Zhur.* 4, Sci. Pt. 19-35(1929); *J. Russ. Phys.-Chem. Soc.* 61, 699-712(1929).—T. set forth (*C. A.* 23, 3926; 21, 3899) that carbopyrotritaric ester (I) forms in concd. HBr a yellow bromide, which on a drying plate is rapidly changed to a garnet-red, and then finally decomposed to the original I in the form of a yellow oil. By this method of formation of halofurfuran derivs., the velocity of the furfuran ring formation from *p*-diketones was studied. Knorr (*Ber.* 17, 2863(1884)) had shown that on dissolving the diethoxydiacetosuccinic acid (II) in concd. HCl there is produced monoethoxycarbopyrotritaric acid (III). T. and R. suggest that first under the influence of concd. HCl the closing of the 1,4-diketone with formation of a furfuran ring and liberation of H<sub>2</sub>O takes place, and is then followed by sapon., with the dil. HCl, of one of the ester groups of the diester with formation of III. If the presence of diethoxycarbopyrotritaric acid could be demonstrated, there would be a ground

to presume that the velocity of cyclic transformation of the 1,4-diketone to the furfuran is greater than the sapon. of one of the ester groups. **II** was brominated by treating it in HBr (d. 1.78) with Br in concd. HBr, the yellow ppt. of bromide was dried first in a desiccator filled with HBr fumes, and then over NaOH until the decompn. of the bromide to diethoxycarbopyrotritaric acid, a yellow oil, b. 275–8° was completed. From this it may be concluded that these yellow and red bromides obtained from **II** are derivs. of diethoxycarbopyrotritaric acid, while the product of their decompn., after loss of Br, is a pure diester of this acid, and secondly that in Knorr's expt. the cyclic closing of 1,4-diketones to a furfural ring proceeds much faster than it is evident from his data.

CHAS. BLANC

**Addendum to the paper on "Pyridine-containing iron carbonyls."** W. HIEBER AND F. SONNEKALB. *Ber.* 62B, 422(1929); cf. *C. A.* 23, 837.—The method of prepn. of Fe carbonyls contg. pyridine is to be stricken from the literature, since it is based upon an incorrect gas analysis.

EMIL KLARMANN

**Monoarylguanidines. II. Benzoxazoleguanidine.** G. B. L. SMITH, J. H. KANE AND C. W. MASON. *J. Am. Chem. Soc.* 51, 2522–7(1929); cf. *C. A.* 23, 1399.—o-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> (100 g.) in 100 cc. concd. HCl and 100 cc. 95% EtOH, heated 15 min., then treated with 80 g. (CNNH<sub>2</sub>)<sub>2</sub> and heated for 2 hrs., gives 130 g. benzoxazoleguanidine(I), as the HCl salt, NH<sub>3</sub> being also formed. I seps. with 1 mol. H<sub>2</sub>O in very pale yellow plates. The anhyd. I m. 182–4°; the HCl salt, m. 254–5°, sulfate, m. 280–1°, nitrate, m. 219–20°, and picrate, m. 247–8°, were also prepd. Di-Ac deriv., m. 209–10°; methiodide, m. 192–4°. Crystallographic data are given for the monohydrate and the salts of I. The above reaction gives direct proof of the presence of the CN group in the (CNNH<sub>2</sub>)<sub>2</sub> mol., which probably is a tautomeric compd. and an equil. product H<sub>2</sub>NC(:NH)NHCN  $\rightleftharpoons$  H<sub>2</sub>NC(:NCN)NH<sub>2</sub>.

C. J. WEST

**Constitution of the red isomeride of creatinine picrate responsible for Jaffe's color reaction.** WINSTON K. ANSLOW AND HAROLD KING. *J. Chem. Soc.* 1929, 1210–6.—The existence of a red isomeric form of creatinine picrate (I) (cf. Greenwald and Gross, *C. A.* 18, 2130) is confirmed but the constitutional formula proposed by Greenwald (*C. A.* 19, 1853) is criticized, A. and K. proposing that combination of creatinine and picric acid in alk. soln. takes place through coordination of the NO<sub>2</sub> group with the enolic group and development of a new center of acidity. Detailed directions are given for the prepn. of I, using 1 mol. of each of the components; it seps. with 1 mol. H<sub>2</sub>O, turns yellow between 160° and 70° and m. about 213°; the excess of picric acid suggested by G. is unnecessary. Boiling I with H<sub>2</sub>O until a clear yellow soln. is obtained and cooling give the yellow isomer (II), m. 220–1°. Shaking I or II with satd. Ba(OH)<sub>2</sub> for 0.5 hr. gives the red Ba salt, which is the Ba salt of a dibasic acid. In the presence of 2 equivs. of Ba(OH)<sub>2</sub> a normal Ba salt is formed, while with an excess of Ba(OH)<sub>2</sub> a partly basic salt results. Concd. HCl liberates I. Addn. of creatinine to alk. solns. of 2,4-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>OH and of 3-methylpicric acid gives orange-red solns., although a few min. is required for the color to develop; alk. solns. of these compds., 2,6-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>OH and 2,4,7-(O<sub>2</sub>N)<sub>2</sub>HO<sub>2</sub>SC<sub>10</sub>H<sub>4</sub>OH contg. creatinine, gradually treated with N HCl, give a transient red color which at neutrality pervades the liquid and is temporarily stable, but disappears on addn. of excess of acid. 2,4-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>OH in abs. EtOH and Me<sub>2</sub>CO gives with EtONa a deep red soln., from which ppts. a brick-red ppt., which explodes on heating; it is a mixt. of about 84.5% C<sub>6</sub>H<sub>3</sub>O<sub>5</sub>N<sub>2</sub>Na. C<sub>3</sub>H<sub>5</sub>ONa and 15.5% C<sub>6</sub>H<sub>3</sub>O<sub>5</sub>N<sub>2</sub>Na.

C. J. WEST

**The constitution of quinovose.** F. VOTOČEK. *Collection Czechoslov. Chem. Comm.* 1, 231–8(1929).—Quinovose (I), a methylpentose derived from quinovin, a principle of various species of cinchona, was proved to be an aldose. It was oxidized with Br<sub>2</sub> water and the quinovinic acid (II) thus obtained was reduced with Na-Hg, yielding I. Furthermore, I responds positively to the Rosenthaler fuclisin test. The [α]<sub>D</sub> of I is 35°. An aq. soln. of II, freshly prepd., is d-rotatory but the rotation diminishes as it stands, probably as the result of the severing of the lactone ring. On the other hand, when 0.5012 g. of the Ba salt was dissolved in 20 cc. of 0.2 N HCl the rotation in a 20-cc. tube (Fric's app.) [α] rose from an immediate reading of 10° to 20° after 22 hrs., after which time no further change took place. II does not reduce Fehling soln.

I. M. LEVINE

**The identity of quinovose with d-glucomethylose (isorhodeose).** F. VOTOČEK AND F. RÁČ. *Collection Czechoslov. Chem. Comm.* 1, 239–44(1929); cf. *C. A.* 22, 2740; 23, 2939.—Quinovose is found to be identical with isorhodeose, since when reduced with Na-Hg (3%) they both yield isorhodeitol. The identity of the dibenzylidene deriv. of the latter confirms this. This finding was missed by earlier workers because the

m. p. of the osazone of quinovose was too high, perhaps because of the presence of another sugar, the osazone of which melts very high.

**Structure of  $\alpha$ -methyl xyloside.** F. P. PHELPS AND C. B. PURVES. *J. Am. Chem. Soc.* **51**, 2443-9 (1929); cf. *C. A.* **22**, 3140.—Trimethyl- $\alpha$ -methylxyloside, prepd from pure cryst.  $\alpha$ -Me xyloside and purified by distn., shows  $n_D^{25}$  1.4397,  $[\alpha]_D^{20}$  121.5° (CHCl<sub>3</sub>), 112.7° (H<sub>2</sub>O), 122.2° (MeOH). The  $\beta$ -deriv. was prepd. from cryst.  $\beta$ -Me xyloside and also from pure xylose, using the Me<sub>2</sub>SO<sub>4</sub>-NaOH method. After purification by recrystn., the product from the 1st method m. 51°,  $[\alpha]_D^{20}$  -69.5° (CHCl<sub>3</sub>), 81.7° (H<sub>2</sub>O), while that from the 2nd method has  $[\alpha]_D^{20}$  -59.6° (CHCl<sub>3</sub>). As this value, which is about 10° low, did not change appreciably on recrystn., it is concluded that this method gives a less pure product. On hydrolysis both products yield the same cryst. trimethylxylose; thus these 2 substances contain the same ring structure, forming an  $\alpha$ - and  $\beta$ -pair. They have thus been definitely correlated for the 1st time and likewise the parent substances,  $\alpha$ - and  $\beta$ -Me xylosides, from which they were derived. The purified trimethyl- $\alpha$ -xylose m. 91-2°,  $[\alpha]_D^{20}$  24.2° (CHCl<sub>3</sub>, final); 64.5° (H<sub>2</sub>O, initial), 17.7° (final). For the most part the consts. given differ markedly from those previously recorded.

C. J. WEST

**Mechanism of tautomeric interchange and the effect of structure on mobility and equilibrium.** IV. Further evidence relating to the mechanism of acid catalysis in the mutarotation of nitrogen derivatives of tetraacetylglucose. JOHN WM. BAKER *J. Chem. Soc.* 1929, 1205-10; cf. *C. A.* **22**, 3634.—In *C. A.* **22**, 3395, 2 types of catalysts for the mutarotation of certain N derivs. of sugars were recognized: Those which attack the ionizing proton directly and those which facilitate its liberation indirectly, this class including strong acids. In the case of derivs. of very strong bases, it was considered possible that actual coordination of the catalyst proton might occur. The resulting salt might thus have acquired the necessary mobile H and exhibit mutarotation consequent on the equil of the cationic system. In order to test this possibility various tetraacetylglucose derivs. of the type required have been prepd.; the solns of their HCl derivs. in abs. or 90% EtOH do exhibit a change in rotation in accordance with the kinetics of unimol. reaction. The change, however, does not appear to be due to the interconversion of the  $\alpha$ - and  $\beta$ -forms but to slow fission of the deriv. into the parent tetraacetylglucose and the HCl of the base. A similar phenomenon is observed when the free sugar derivs. are examd. in AcOEt in the presence of a little HCl. On the basis of these negative results, it seems probable, therefore, that for mutarotation, dependent on the simple isomeric change, to be possible, the original sugar deriv. itself must contain a separable H atom (cf. Baker, Ingold and Thorpe, *C. A.* **18**, 972). *p*-Methylbenzylmethylamine,  $b_p$  84°; *HBr* salt m. 166°; *di*-*p*-methylbenzylmethylamine,  $b_p$  about 180°; *p*-Cl deriv.,  $b_p$  101° (*HBr* salt, m. 196°); *di*-*p*-Cl deriv.,  $b_p$  about 200°; *p*-CN deriv.,  $b_p$  143° (*HBr* salt, m. 209-10°); *di*-*p*-CN deriv., m. 65° (*HCl* salt, m. 250° (decompn.)). Tetraacetylglucosidyl bromide (I) (1 mol) and the amine (2 mols.), gently warmed in Et<sub>2</sub>O until most of the Et<sub>2</sub>O evaps., give the following derivs. of the tetraacetylglucose: Benzylmethylamide, m. 125° (*HCl* salt, m. 80°), *p*-methyl deriv., m. 99-100° (*HCl* salt, m. 175° (decompn.)), *p*-Cl deriv., m. 104.5° (*HCl* salt, m. 137° (decompn.)); *p*-CN deriv., m. 85.6° (*HCl* salt, m. 146° (decompn.)). When 30 g. I is added to 50 cc. piperidine at 0-10° and then a large vol. Et<sub>2</sub>O added, *piperidide A*, m. 123°, is formed (*HCl* salt, m. 126°); when the I is added in 0.5 g. portion to the piperidine dild. with 0.5 its vol. Et<sub>2</sub>O, there results *piperidide B*, m. 136° (decompn.); the *HCl* salt is unstable, m. 130.1° (decompn.), if rapidly crystd., slower crystn. appears to give a deacetylated deriv., m. 126-7°. The *diethylamide-HCl*, m. 152-3°; the *dimethylamide-HCl*, m. 159-60°. Data are given for the rate of fission of the various derivs. in 90% EtOH and abs. EtOH at 24.5°.

**Constitution of glucosemonoacetone, glucosediacetone and of the derived 3,5-trimethylglucose and 3-monomethylglucose.** CAMERON G. ANDERSON, WM. CHARLTON AND WALTER N. HAWORTH. *J. Chem. Soc.* 1929, 1329-37.—Glucosediacetone, m. 109-10°,  $[\alpha]_D^{17}$  -18.6°, yields a mono-Me deriv.,  $b_p$  105-6°,  $[\alpha]_D^{21}$  -31.4°,  $n_D^{17}$  1.451; which, on hydrolysis, yields 3-methylglucose, m. 160-1,  $n_D^{17}$  1.043°  $\rightarrow$  55; (after 19.5 hrs., H<sub>2</sub>O,  $c$  1.33); proof of the position of the Me group is furnished by methylation, which gives the usual tetra-Me glucopyranose, m. 90.4° (anilide, m. 135°); the phenylosazone, m. 178-9° (Irvine and Scott, *C. A.* **7**, 2383, gives 164-5° and may be identical with that from 3-methylfructose, since the m. p. and rate of mutarotation appear to be identical. Trimethylglucosemonoacetone,  $[\alpha]_D^{20}$  -29.5° (MeOH,  $c$  1.55),  $n_D$  1.4470, on hydrolysis yields 3,5,6-trimethylglucose,  $b_p$  104.5°

134°,  $[\alpha]_D -44.1$  (EtOH,  $c$  1.49),  $-25.9$  (H<sub>2</sub>O,  $c$  1.3); phenylosazone,  $m.$  70-2°; methylation gives 2,3,5,6-tetramethylglucose, and a by-product,  $m.$  97-8°, contg. 53.9% MeO. The identification was supported by conversion into 2,3,5,6-tetramethyl- $\gamma$ -gluconolactone,  $m.$  25.5-6°. These results indicate that the structural form of glucose in its Me<sub>2</sub>CO derivs. is that of glucofuranose and support the following constitutional formulas for the monoacetone (I) and the diacetone (II):

(I)

(II)

**Constitution and  $\alpha$ - and  $\beta$ -fructosediacetones.** The alleged oxidative degradation of the derived monomethyl- and tetramethylfructose. CAMERON G. ANDERSON, WM. CHARLTON, WALTER N. HAWORTH and VINCENT S. NICHOLSON. *J. Chem. Soc.* 1929, 1337-46.— $\alpha$ -Fructosediacetone (I) yields a Me deriv. having the consts. given by Irvine and Hynd (*C. A.* 3, 2933); the 3-methylfructose (II) obtained therefrom  $m.$  128-30°,  $[\alpha]_D^{20} 84.1^\circ$  (after 15 min.)  $\rightarrow -53.5^\circ$  (H<sub>2</sub>O,  $c$  0.92); phenylosazone,  $m.$  177-9° (I and H. give 142-4°; cf. preceding abstr.). I. and H. state that this is oxidized with Br-H<sub>2</sub>O to MeOCH<sub>2</sub>CH(OH)CH(OH)CO<sub>2</sub>H; repetition of this expt. shows that II is not attacked by Br-H<sub>2</sub>O or only very slightly; II forms a complex with Ba(OH)<sub>2</sub>, which accounts for the Ba salt of the supposed degradation product of I and H. Oxidation of tetramethylfructose and hydrolysis of the ester, followed by oxidation with KMnO<sub>4</sub>, gives *d*-2,3,4-trimethyl- $\delta$ -arabonolactone,  $m.$  44°,  $[\alpha]_D^{18} -177.3^\circ$ , diminishing to  $-111.4^\circ$ ,  $-83^\circ$  and  $-10.2^\circ$  after 1 hr., 2 hrs. and 2 days, resp. Combined hydrolysis and methylation of K fructuronate dilactone from  $\beta$ -fructosediacetone (III) give Me tetramethylfructuronate (IV),  $m.$  102-3° (amide,  $m.$  118-9°). Hydrolysis of the K salt by heating with *N*H<sub>2</sub>SO<sub>4</sub> for 24 hrs., followed by methylation, gives IV and a liquid ester,  $b.$  87°, whose amide  $m.$  100-1°, identical with that obtained by the oxidation of tetramethyl- $\gamma$ -fructose (*C. A.* 21, 3182). These results indicate the following formulas:

(I)

(III)

C. J. WEST

**Cellulosexanthoacetic acid.** TADASHI NAKASHIMA *Z. anorg. Chem.* 42, 546-9 (1929); cf. *C. A.* 22, 2744.—The prepn. of cellulosexanthoacetic acid (I), HO<sub>2</sub>CCH<sub>2</sub>SO cellulose, from cellulose xanthate and ClCH<sub>2</sub>CO<sub>2</sub>H is described. The Na salt he acid is sol. in water but the free acid is insol. The alk. soln. decomps. on standing regenerates cellulose and HSCH<sub>2</sub>CO<sub>2</sub>H. The Cu, Ag, Hg, Ba and Zn salts of the were prepd. by adding the metallic salt soln. to an alk. soln. of I. The Cu salt is and the others are white. J. G. McNALLY

**Constitution of starch.** KURT H. MEYER, HEINRICH HOPFF and H. MARK. *Ber.* 1103-12 (1929).—Since maltose derivs. are formed from starch not only by enzymic degradation but also by relatively simple chem. reactions (e. g., treatment with *tr*) it may be assumed that maltose is already in some way preformed in starch and  $\alpha$ -unions are present in starch but it is still a question whether or not  $\beta$ -unions mate with the  $\alpha$ -unions. As with cellulose (*Z. physik. Chem.*, Abt. B, 2, 115 (1929)), authors have now used the Hudson rule as a guide in detg. the constitution of st. As shown in the accompanying figure the increments of the rotation of  $\beta$ -ose (corresponding to the 1-C atom and to the rest of the mol., resp.) are all present -maltose also and the latter contains a glucose residue corresponding completely glucose residue in an  $\alpha$ -1,4-union in a chain. By subtracting the mol. rotation of

$\beta$ -glucose from that of  $\beta$ -maltose it is possible, therefore, to calc. the mol. rotation of a compd. consisting of 1,4-glucosyl groups united to each other through  $\alpha$ -bridges. Since the rotation of starch in  $H_2O$  varies widely and is difficult to det. because of the opalescence of the solns.,  $HCONH_2$  was used as the solvent; 0.5 g. starch, dried 12 hrs. at  $90^\circ$  over  $P_2O_5$  at 0.1 mm. pressure, was heated on the  $H_2O$  bath in 100 cc. freshly

distd.  $HCONH_2$ , a clear soln. generally resulting in 2 hrs. Only rice starch did not dissolve completely in 5 hrs. and on standing most of the dissolved part sepd. as a viscous jelly. The following values for  $[\alpha]_D^{21}$  were obtained: native potato starch,  $198^\circ$ ; potato starch extd. 11 times with 10 parts of  $H_2O$  for 6 hrs.,  $208^\circ$ ; amylopectin (Pringsheim),  $216.6^\circ$ ; amylose (P.),  $204^\circ$ ; native arrowroot starch,  $204^\circ$ ; arrowroot starch, defatted and pptd. from  $HCONH_2$  with alc.,  $210^\circ$ ; native wheat starch, defatted,  $220^\circ$ ; glycogen,  $201^\circ$ . Starch, therefore, in  $HCONH_2$  has a rotation of about  $220^\circ$ , while the calcd. value for a chain consisting solely of  $\alpha$ -1,4-glucosyl residues is  $226^\circ$ , as shown by the table below;  $\beta$ -unions should betray themselves by a lower rotation, for a chain of purely  $\beta$ -1,4-glucosyl unions has a sp. rotation of only about  $20^\circ$ .

	$[\alpha]_D^{21}$	Mol. rotation	Mol. rotation $\alpha$ -1,4-glucosyl res
$\beta$ -Maltose	$112^\circ$	$403.2^\circ$	
$\beta$ -Glucose	$20^\circ$	$36.0^\circ$	$367.2^\circ$
Equil. maltose	$126.0^\circ$	$453.6^\circ$	
Equil. glucose	$52.6^\circ$	$94.68^\circ$	$358.92^\circ$
			$221.6^\circ$

In boiling  $H_2O$  the rotation first increases as dispersion and solvation of the micelles progresses, and then begins to fall because of beginning hydrolysis; the highest value obtained ( $212^\circ$ ) therefore probably comes nearest to the true rotation; from the observed values of  $[\alpha]_D$  given below for 4 pairs of compds., the calcd. values for the  $\alpha$ -1,4-chain in  $H_2O$  are  $231^\circ$ ,  $230^\circ$ ,  $216^\circ$ ,  $230^\circ$ , resp.:  $\alpha$ -maltose  $168^\circ$ ,  $\alpha$ -glucose  $141.2^\circ$ ,  $\beta$ -maltose  $118^\circ$ ,  $\beta$ -glucose  $17.5^\circ$ ;  $\beta$ -Me maltoside  $78.8^\circ$ ,  $\beta$ -Me glucoside  $34.2^\circ$ , equil maltose  $136^\circ$ , equil. glucose  $52.5^\circ$ . The great variability of starch indicates a much greater variation in the length of the primary valence chains than in the case of cellulose. A study of the kinetics of starch cleavage showed that acid cleavage remains of the same order of magnitude from the beginning to the end and has the velocity of a glucosidic hydrolysis. With 50 cc. of 1% maltose and 50 cc. of  $N H_2SO_4$  quite a good const. for a monomol. reaction was obtained ( $k_2 \cdot 10^3 = 1.07-1.14$  at  $70^\circ$ , 2.18-2.54 at  $80^\circ$ , 10.7-13.5 at  $90^\circ$ ). Amylose also gave a fairly good const. (0.36-0.47, 1.28-1.54, 4.1-5.6, resp.); only at  $90^\circ$  did there seem to be an indication of a slow uniform rise. As a matter of fact, the hydrolysis of amylose must be considered as a complex series of reactions, the last stage of which (hydrolysis of the maltose) is known. As a first approximation, a 2-stage reaction was taken as the basis of calcn.; the values of  $k_1 \cdot 10^3$  so calcd. were 1.0 at  $70^\circ$  and 2.4 at  $80^\circ$ . Therefore the union of the glucose residues in amylose must be essentially the same as that of the 2 residues in maltose. The large temp. coeff. indicates that the process is a normal chem. reaction and not a diffusion phenomenon. Roentgenographic studies on starch have thus far established only that certain parts of starch have a lattice arrangement which is related to the presence of  $H_2O$  of hydration. It has thus far been impossible, by spinning of threads, tension or pressure so to orient the starch micelle that it showed a fiber diagram; on the other hand, the lattice structure of starch is much more easily destroyed than that of cellulose and, when once destroyed, it cannot be regenerated. Under 20,000 atm. pressure starch loses its roentgenogram. Likewise, starch swollen in  $HCONH_2$  is amorphous when pptd. out. Of amylose and amylopectin only the latter is crystalline. The fact that the starch micelles can be oriented not at all or only with difficulty suggests that the primary valence chains are shorter than in cellulose and not parallel in elongated bundles but in some other, not yet clearly recognized arrangement.

C. A. R.

A crystalline difructose anhydride from hydrolyzed inulin. RICHARD F. JACKSON

AND SYLVIA M. GOERGEN. *Bur. Standards J. Research* **3**, 27-38(1929).—Inulin upon hydrolysis with dil. acids yields solns. contg. in 100% solid matter 91.8% fructose (I), 94.8% reducing sugar and a 5.2% unfermentable residue. The residue has a  $[\alpha]_D^{20}$  55° and is hydrolyzed solely to I. It is 25 times as resistant to hydrolysis as the remainder of the inulin mol. Acetylation of the original residue yielded a mixt. of acetates, one of which crystd. in 30% yield in the form of prismatic needles of  $[\alpha]_D^{20}$  0.54°. This was found to be the hexaacetate of a disaccharide contg. but 6 hydroxyl groups. The mother liquors from the cryst. acetate contained one or more acetylated difructoses with a mean  $[\alpha]_D^{20}$  31°. The cryst. hexaacetate upon deacetylation yielded a cryst. difructose anhydride of  $[\alpha]_D^{20}$  27°. The latter was hydrolyzed to I. G. C. STROUSE

**The action of ozone on cyclogeraniolenes.** RENÉ ESCOURRON. *Bull. soc. chim.* **43**, 1277-9(1928).—Ozonides of cyclogeraniolene (I), methyl-(II) and phenylcyclogeraniolene (III) were prepd. by treatment with  $O_3$ . During the treatments, white fumes were evolved and the odor of  $CH_2O$  was apparent. Decompn. of the ozonides with boiling water gave  $CH_2O$  and a strong menthol odor resembling cyclic ketones of this series. On the basis of the results obtained the following formulas are given, resp., for I, II and III:  $Me_2C.CH_2.C(:CH_2).(CH_2)_2.CH_2$ ,  $Me_2C.CHMe.C(:CH_2).(CH_2)_2.CH_2$  and  $Me_2C.CHPh.C(:CH_2).(CH_2)_2.CH_2$ . Tieman's methylcyclohexene formula for II should in reality be a methenecyclohexane.

**Synthesis of isoamylcyclopentane.** JOHN MCA. HARRIS, JR. *J. Am. Chem. Soc.* **51**, 2591(1929).—Isoamylcyclopentanol, from cyclopentanone and iso-AmBr,  $b_{17}^{101}$ ,  $d_4^{26}$  0.8848,  $n_D^{26}$  1.4549; dehydration with  $p-MeC_6H_4SO_3H$  gives isoamylcyclopentene,  $b_{760}^{168-70}$ ,  $d_4^{25}$  0.8010,  $n_D^{25}$  1.4467; catalytic reduction gives isoamylcyclopentane,  $b_{760}^{168-70}$ ,  $d_4^{25}$  0.7837,  $n_D^{25}$  1.4321. C. J. WEST

**Hydrolysis of naphthenic acids at elevated temperatures and cracking under pressure of hydrogen.** V. N. IPAT'EV AND A. D. PETROV. *Zhur. Prikladnoi Khim.* **2**, 327-35(1929).—Exptl. work was done with acids b. 260-360° and having an acid no. of 233 and an av. mol. wt. of 240. Heating for 5 hrs. at 440-60° (temp. measurements were approx.) and 210 atm. of 100 g. acids, 50 cc. water, and 10 g.  $Al_2O_3$  resulted in a yield of 80 cc. of oil and 55 cc. of water contg. AcOH and other acids of the same series. The oil had an acid no. 131.4 and on distn. yielded 19 g., b. 65-150° (5% sol. in NaOH and 20% in  $H_2SO_4$  of d. 1.84), 90 g., b. 150-260° (35% sol. in NaOH and 25% in  $H_2SO_4$ ; acid no. 101), and 80 g., b. above 260° (2 g. of yellow oil, 40 g. of acids with acid no. 176.7 and residue of d. < 1). Fractions b. below 260° contained paraffins, naphthenes, some aromatics, 20-25% unsatd. hydrocarbons, 10-15% ketones, naphthenic acids deprived of their disagreeable odor and other O compds. Heating for 4 hrs. at 440° and 250 atm. of 100 g. acids, 50 cc. water, and 15 g. NaOH, yielded 20% unsatd. compds. or considerably less than by heating under atm. pressure (C. A. **20**, 2152). Heating for 8 hrs. at 460-70° and 240 atm. of 100 cc. tetralin, 50 cc. water, and 10 g.  $Al_2O_3$  yielded 40 cc. of water layer and 90 cc. of hydrocarbons contg. only little  $C_6H_6$ , but large amts. of aromatic hydrocarbons of high b. p. The yield of low boiling fractions was smaller than in cracking in presence of  $H_2$  (C. A. **22**, 396). Heating for 6 hrs. at 460° and 215 atm. of 35 cc. hexahydrotoluene, 50 cc. water, and 20 g.  $Na_2CO_3$  was of no effect and only traces of carbon were found. Heating at 460° and 175 atm. for 3 hrs. of 60 g. paraffins (m. 56-8°), 50 cc. water, and 10 g. NaOH yielded 27 cc. of cracked products. On longer heating up to 70% of liquid cracked products was obtained. 80% of these products b. below 200° and contained about 10% unsatd. compds. Palmitic acid could not be decompd. under similar conditions, which indicates stability of fatty acids of the paraffin series. Heating for 8 hrs. at 460° and 190 atm. of 75 cc. naphthenic acids and 5 g.  $Al_2O_3$  in presence of  $H_2$  showed that less O compds. were obtained than by cracking in presence of water, while the amt. of low-boiling compds. was higher. V. KALICHEVSKY

**The catalytic condensation of cyclohexanone and cyclohexene during heating.** A. D. PETROV. *Bull. soc. chim.* **43**, 1272-6; *J. Russ. Phys.-Chem. Soc.* **60**, 1435-40 (1928).—Heating cyclohexanone (80 g.) to 320° under 30 atm. with  $Al_2O_3$  for 24 hrs. results in both dehydration and pyrogenic disocn., giving a cyclohexylidene-cyclohexanone fraction  $b_{15}^{142-5}$  (I) and a fraction  $b_{14}^{214-9}$  corresponding to dicyclohexylidene-cyclohexanone and dodecahydrotriphenylene (15 g.), m. 224-5°. Semicarbazone of I m. 178-9°. Cyclohexene (60 g.),  $Al_2O_3$  (6 g.) for 24 hrs. at 400-40° gave a gas ( $C_nH_{2n+2}$ ), aromatic hydrocarbons, and higher-boiling fractions. F. C. H.

### Catalytic influences in three-carbon tautomerism. I. Sodium alkoxides.

A. R. KON AND REGINALD P. LINSTAD. *J. Chem. Soc.* 1929, 1269-82.—On the ionic view of the mechanism of tautomeric change, the formation of the active form in a 3-C prototropic change, *viz.*, the anion, will be influenced, apart from structural factors, by the nature of the catalytic medium. The more affinity the medium has for the proton, the more ready will be the tautomeric interconversion. The standard conditions chosen were 1 equiv. of *N* EtONa at 25°. Using cyclohexylideneacetone (I) and cyclohexenylacetone (II), both ketones pass rapidly into the equil. mixt., which contains 30% of I. The rate of equilibration and the point of equil. are the same when com abs EtOH is used in place of the specially dried solvent, but large amts. of H<sub>2</sub>O diminish the rate of equilibration. II reaches equil. in about 60 min., while I requires much longer. The difference is more marked with MeONa and an equil. mixt. is not obtained from I even at the end of 48 hrs. 1-Ethoxycyclohexylacetone semicarbazone, m. 174°. *MeO deriv.*, m. 181-2°. Other alkyl oxides produce the same equil. mixt., the order of efficiency being iso-PrONa, PrONa, EtONa, MeONa, the iso-PrONa being the most active. NaOH in 75% EtOH is much less effective than EtONa. The action of EtONa upon Et cyclohexylideneacetate (III) and Et Δ<sup>1</sup>-cyclohexenylacetate (IV) was also studied. III gives an equil. mixt. contg. 57% of IV, a gradual change taking place through 250 hrs.; IV gives the same mixt. but this value is attained in 63 hrs. The retarding effect of H<sub>2</sub>O is not attributed to a sp. anticatalytic action but merely to greatly increased hydrolysis which removes both the ester and the catalyst. IV is hydrolyzed more rapidly than III; this does not, however, affect the equil. The true equil. is considered to be 62% of IV. *Et 1-ethoxycyclohexylacetate*, b<sub>p</sub> 122°, d<sub>4</sub><sup>20</sup> 0.9865, n<sub>D</sub><sup>20</sup> 1.45753.

C J WEST

**Superheating of homogeneous organic compounds. V. Naphthenic aryl esters and experiments on the mechanism of their transformations.** SIEGFRIED SKRAUP AND OTMAR BINDER. *Ber* 62B, 1127-38(1929); cf. *C. A.* 21, 2463.—As model expts for the behavior of aryl naphthenates in general, other ring systems have been studied to det. whether the observation made with Ph cyclohexanecarboxylate (I) holds good in general. Such proved to be the case, for Ph cyclopentane- (II), cyclobutane- (III) and (probably) cyclopropanecarboxylate (IV) isomerize into the corresponding *o*-hydroxy phenyl ketones, characterized by analysis and the Dimroth boric ester reaction. The sensitivity to temp. increases quite uniformly in the order I → II → III, the temps. required for isomerization being about 360°, 330° and 300°, resp. When the C atom carrying the CO<sub>2</sub>H group also carries a Me group, the compds. are markedly more resistant and remain practically unchanged at 360°; at 390° they do not isomerize but decomp. into methylcyclohexene or -pentene and HCO<sub>2</sub>Ph, the latter decompg. further into PhOH and CO. It had been suggested that in the isomerization of cyclohexyl Ph ether into *o*-C<sub>6</sub>H<sub>11</sub>C<sub>6</sub>H<sub>4</sub>OH the ether first breaks down into cyclohexene and PhOH. I-III could similarly be conceived as breaking down into PhOH and cyclic ketenes but this would not be possible with their *α*-alkyl derivs. To be sure, Ph<sub>2</sub>C:CH<sub>2</sub> gently heated with PhOH forms not *o*-Ph<sub>2</sub>CHCOC<sub>6</sub>H<sub>4</sub>OH but Ph<sub>2</sub>CHCO<sub>2</sub>Ph, however, as found with J. KAUPP, when Ph<sub>2</sub>CHCO<sub>2</sub>Ph or PhCH<sub>2</sub>CO<sub>2</sub>Ph is heated in H at 300° it splits off 85-95% of the theoretically possible amt. of PhOH in a few hrs. and the resulting ketene polymerizes, but if the decompn. is effected under a reflux or in sealed tubes the PhOH reacts with a part of the ketene to form the ketone *o*-Ph<sub>2</sub>CHCOC<sub>6</sub>H<sub>4</sub>OH or *o*-PhCH<sub>2</sub>COC<sub>6</sub>H<sub>4</sub>OH. With catalysts (Cu bronze, silicates, etc.) the decompn. temp. can be greatly lowered (down to 140°) and the yield of HO ketone materially improved. Again, the intermediate formation of ketenes can be detected by means of PhN:NPh, which with Ph<sub>2</sub>C:CH<sub>2</sub> yields a heterocyclic compd Ph<sub>2</sub>C.NPh.CO yielding, on superheating, chiefly Ph<sub>2</sub>C:NPh and PhNCO.

both of these substances, along with PhOH, were readily obtained when Ph<sub>2</sub>CHCO<sub>2</sub>Ph was heated with PhN:NPh, and PhNCO was identified with certainty when PhCH<sub>2</sub>CO<sub>2</sub>Ph was similarly heated. 1-Methylcyclohexane-1-carboxylic acid (V) was obtained rather surprisingly by alk. KMnO<sub>4</sub> oxidation of the methylcyclohexylphenol obtained by Schrauth and Quasebarth from PhOH and methylcyclohexene. The splitting of

of HCO<sub>2</sub>Ph observed in the esters of the type

$$\begin{array}{c} \text{---CH}_2 \\ \text{---CH}_2 \end{array} \text{C} \begin{array}{l} \text{Me} \\ \text{CO}_2\text{Ph} \end{array} \quad (\text{VI}) \text{ had hitherto been}$$

noted only with CH<sub>2</sub>:CHCO<sub>2</sub>Ph, which thereby yields C<sub>3</sub>H<sub>2</sub> and had been assumed to be an intermediate product in the cleavage of satd. paraffins from fatty acid Ph esters. The above observation suggested that in this reaction the fatty acid ester first

splits off  $\text{HCO}_2\text{Ph}$  with formation of a  $\Delta^1$ -alkylene, which then decomps. into  $\text{C}_2\text{H}_2$  and a satd. paraffin. This suggestion was tested with hexadecylene (VII), which is thus obtained from Ph margarate, but the VII yielded no  $\text{C}_2\text{H}_2$ ; except for the formation of a dimer and still higher-boiling products it remained for the most part unchanged. Investigations by v. Braun, which are still under way, have shown that in the greater part of the naphthenic acids in petroleum the  $\text{CO}_2\text{H}$  group is several C atoms removed from the alicyclic ring, thus occupying an intermediate position between the above alicyclic nucleus- $\text{CO}_2\text{H}$  acids and ordinary fatty acids, and it seemed of interest to det. how their Ph esters would behave on superheating. Expts on an acid  $\text{C}_{10}\text{H}_{18}\text{O}_2$  (VIII) from Galician petroleum showed that the aryl esters behave like neither those of the nucleus-carboxylated naphthenic acids nor those of the fatty acids;  $\text{CO}_2$  is split off and the "naphthenyl" and Ph residues combine to an alicyclic-substituted benzene,  $\text{C}_{11}\text{H}_{17}\text{Ar}$  (IX), the aromatic character of which can be shown by sulfonation. The aryl esters were prepd. by heating the acid chlorides (obtained with  $\text{SOCl}_2$ ) with an excess of PhOH at 100–40°. The superheating and working up of the products were carried out as described in earlier papers. Cyclopentanecarboxylic acid, obtained in 91.6% yield from cyclopentanecarboxylic acid in MeOH with  $\text{PdCl}_2$ -gum arabic and H at room temp.,  $b_{14}$  112–3°. Ph ester (II) (65% yield),  $b_{13}$  137°, does not solidify –15°; heated 72 hrs. at 340°, 4.5 g. gives 0.25 g. cyclopentyl *o*-hydroxyphenyl ketone, pale yellow,  $b_{13}$  125–35°, does not solidify –15°. III (54%),  $b_{13}$  127°,  $d_{17}^{20}$  1.0747; 13 g. yields after 72 hrs. at 300° 1.8 g. cyclobutyl *o*-hydroxyphenyl ketone,  $b_{13}$  139–40°, gives a dark violet color with alc.  $\text{FeCl}_3$  (as by-product was obtained 0.4 g. of the Me ester of the acid,  $b_{13}$  40°, whose vapors produced coughing). Cyclopropanecarboxylic acid, obtained in 38.4% yield from the di- $\text{CO}_2\text{H}$  acid after 8 hrs. by slowly heating it in 3 parts  $\text{C}_{10}\text{H}_8$  to 200°,  $b_{13}$  182–4°. Ph ester (IV) (53%),  $b_{13}$  117–8°; 10 g. gave after 72 hrs. at 360° 0.5 g. substance,  $b_{13}$  85–6°, which gave the boric ester reaction and a brown-red color with alc.  $\text{FeCl}_3$  and contained 76.86% C and 7.94% H (calcd. for  $\text{C}_{10}\text{H}_{10}\text{O}_2$ , 74.04, 6.21). V (yield, 21%),  $b_{13}$  127–8°. Ph ester (65.4%),  $b_{13}$  149–50°. Ph 1-methylcyclopentane-1-carboxylate (69%),  $b_{14}$  137°; the 1-methylcyclopentene formed by superheating was identified by comparison with a product, m. 32°, obtained in 65% yield from 1-methylcyclopentanol slowly heated in H with anhyd.  $(\text{CO}_2\text{H})_2$ ; oxidation with  $\text{CrO}_3$  gave  $\text{AcOH}$  and  $(\text{CH}_3\text{CO}_2\text{H})_2$ . Dimer of VII, m. 52–3°, mol. wt. m camphor 441. Ph ester of VIII (70%),  $b_{13}$  161–71°; 21 g. heated 42 hrs. at 320° and 24 hrs. at 350° gave 0.5 g. of the hydrocarbon IX (Ar = Ph). Anisyl ester (88%), pale yellow,  $b_{13}$  198–210°; 32 g. heated 72 hrs. at 340° gave 0.8 g. anisyl-naphthene,  $b_{13}$  150°, easily sol. in cold concd.  $\text{H}_2\text{SO}_4$  with deep orange-red halochromism.

C. A. R.

**Preparation of pure cyclohexene.** H. I. WATERMAN AND H. A. VAN WESTEN. *Rec trav chim.* 48, 637–9 (1929).—Pure cyclohexene was prepd. from a prepn. of Poulenc, which showed a Br value of 180.1 (calcd. 194.7) and a much too low H bromine value, in the following way. On fractional distn. an almost pure product could be obtained with a hydrogen bromine value 186.2 (calcd. 194.7) and with refractometric consts. which are in rather good agreement with those mentioned in the literature for cyclohexene; on hydrogenation, however, this product yielded some water, thus showing the presence of an impurity contg. O. On fractionating the purified product over Na, pure cyclohexene was obtained with the theoretical bromine and hydrogen bromine values,  $b_{769}$  82.8°,  $n_D$  1.4436,  $n_D$  1.44637,  $n_F$  1.45312,  $n_G$  1.45874 at 20.05.

C. F. VAN DUIN

**The properties of some very dry organic compounds.** JEAN TIMMERMAN. *Bull. soc. chim. Belg.* 38, 160–2 (1929).—Benzene, *p*-xylene, cyclohexane and  $(\text{CH}_2\text{Br})_2$  have been submitted to drastic drying over  $\text{P}_2\text{O}_5$  for a period of 35 months. This treatment did not affect the m. p. or the surface tension. These observations agree with those made by Briscoe and co-workers (C. A. 23, 3140). The results obtained with benzene contradict those obtained by Baker.

**Early history of the synthesis of closed carbon chains.** WM. HENRY PERKIN, JR. *J. Chem. Soc.* 1929, 1347–63.—The first Pedler lecture.

C. J. WEST

**Condensation of aromatic aldehydes with nitromethane.** MYSORE GURU SRINIVASA RAO, COLLURAYANA SRIKANTIA AND MYSORE SETHA IYENGAR. *Helv. Chim. Acta* 12, 581–3 (1929).—Condensation of  $\beta$ -resorcyraldehydes with  $\text{MeNO}_2$  was obtained with  $\text{AcONH}_4$  and glacial  $\text{AcOH}$  as catalysts. 2,4-HO(MeO) $\text{C}_6\text{H}_3\text{CHO}$  gives 2-hydroxy-4-methoxy- $\omega$ -nitrostyrene, m. 171–2°. 2,4-(MeO) $\text{C}_6\text{H}_3\text{CHO}$  gives 2,4-dimethoxy- $\omega$ -nitrostyrene, m. 104°. 4,2-MeO(EtO) $\text{C}_6\text{H}_3\text{CHO}$  gives 2-ethoxy-4-methoxy- $\omega$ -nitrostyrene, m. 102°. 5,2,4-O $_2\text{N}$ (MeO) $\text{C}_6\text{H}_3\text{CHO}$  gives 5- $\omega$ -dinitro-2,4-dimethoxy-styrene, m. 214°.

F. J. G. DE LEEUW

**Vapor-phase hydrolysis of phenyl chloride and bromide.** LYMAN CHALKLEY, JR. *J. Am. Chem. Soc.* 51, 2489-95 (1929).—This work was undertaken as a part of a search for new methods for the synthesis of PhOH. PhCl and PhBr are readily hydrolyzed to the extent of at least 25 to 40% by passage of their vapor mixed with steam over silica gel at 500-50° and ordinary pressures. The ability to catalyze the hydrolysis of the phenyl halides is not peculiar to silica gel but is possessed by a variety of hydration catalysts: silica gel, titania,  $Al_2O_3$ ,  $ThO_2$ ,  $ZrO_2$  and blue W oxide. A sample of kaolin showed little activity. Silica gel and  $TiO_2$  appear to be the most active. With silica gel as the catalyst the reaction proceeds at a measurable speed at 300° and above. The products of the reaction are: the halogen acid, PhOH,  $Ph_2O$  and probably smaller quantities of other org. compds. No pronounced halogenation of the PhOH obtained in the primary reaction was noticed and no  $H_2O$ -insol. gases were evolved. The activity of silica gel or  $TiO_2$  which has been fouled by use may be restored by heating the catalyst in air or  $O_2$ . C. J. WEST

**The action of nitrogen chloride on toluene and cyclohexene.** NORBERT STOLL. *Bull. soc. chim. Belg.* 38, 71-96 (1929).—In the light,  $NCl_3$  reacts by substitution with PhMe: both the nucleus and the chain are affected. In the dark, in the presence of  $C_6H_6$ , it reacts by addn. with cyclohexene. However, traces of  $C_6H_5Cl$ , PhCl, HCl and  $NH_3$  have been detected indicating that some substitution occurs. The formation of PhCl is explained by induction due to the simultaneous formation of  $C_6H_5Cl$ . No traces of  $C_6H_5Cl_2$  have ever been detected. ALBERT L. HENNE

**Derivatives of 2,5-dibromonitrobenzene.** L. CHAS. RAIFORD AND B. C. BREN. *J. Am. Chem. Soc.* 51, 2539-41 (1929).—The following derivs. were prepd. by the usual methods. *Tetrabromoazoxybenzene*, m. 217°, 15% yield; *tetrabromoazobenzene*, red, m. 247°, 13% yield; *tetrabromodiazaminobenzene*, yellow, m. 185°, nearly quant. yield; *di-bromophenyldiazonium chloride*, which does not give a phenol when boiled with  $H_2O$  but couples with  $\beta$ - $C_{10}H_7OH$  to give a red dye,  $C_{16}H_{10}ON_2Br_2$ ; the diazoamino compd. could not be rearranged into the isomeric aminoazo compd.; reduction of the diazonium salt with  $SnCl_2$  and HCl did not give the expected hydrazine but regenerated the amine and split off  $NH_3$ . *5,5'-Dibromoazoxy-o-anisole*, straw-colored, m. 121°, 60% yield; *5,5'-dibromoazo-o-anisole*, red, m. 238°, 81% yield; *5,5'-dibromohydrazo-o-anisole*, m. 120-1°, very small yield. *6,6'-Dibromodianisidine*, fawn-colored, m. 168° (th. Bz deriv., m. 274°; dye from diazo compd. and  $\beta$ - $C_{10}H_7OH$ , amorphous red powder, 5,5'-dibromohydrazo-o-phenetole, m. 171-2°, 14% yield. C. J. WEST

**Schiff bases derived from 5-chlorovanillin.** RAYMOND M. HANN, GEORGE S. JAMIESON AND E. EMMET REID. *J. Am. Chem. Soc.* 51, 2586-8 (1929).—The following *5-chlorovanillin* derivs. were prepd. by heating with the amine in 95% EtOH: *o-toluidine*, m. 115° (all m. ps. cor.) (*picrate*, yellow, m. 224°); *p-toluidine*, canary-yellow, in 142° (*picrate*, golden yellow, m. 230°); *m-nitroaniline*, light yellow, m. 160° (*picrate*, orange, m. 190°); *p-chloroaniline*, orange-yellow, m. 128° (*picrate*, orange-yellow, m. 215°); *cymidine*, yellow, m. 146-7°; *p-anisidine*, straw-colored, m. 131° (*picrate*, bright orange, m. 229-30°); *benzidine*, yellow, m. 251-2° (*picrate*, orange, m. 250-60° (decompn.)); *m-aminobenzoic acid*, yellow, m. 207° (*picrate*, orange-red, crystg. with EtOH, m. 211°); *p-aminophenol*, brick-red, m. 150° (*picrate*, orange, m. 224-5° (decompn.)); *o-dianisidine*, orange, m. 188° (*picrate*, golden yellow, decompn. 225°); *bis-nitro-p-toluidine*, yellow, m. 125° (*picrate*, bright yellow, m. 148°). No derivs. could be obtained from *o*- and *p*- $O_2NC_6H_4NH_2$ , 2,4- $Cl_2C_6H_3NH_2$  and  $(O_2N)_2C_6H_3NH_2$ . C. J. WEST

**Action of aromatic amines on nitric esters.** HUGH RYAN AND MICHAEL T. CASEY. *Sci. Proc. Roy. Dublin Soc. [N.S.]*, 19, 101-11 (1928).—The course of the reactions between primary aromatic amines and nitric esters seems to be indirectly hydrolytic. Thus aniline, *o*- and *p*-toluidine, and *m*-xylidine reacted with Et, Bu and Am nitrates to form the nitrate of the base. In those cases which were fully investigated the alkyl deriv. of the base was also formed. The chief reaction between a secondary amine and a nitric ester seems to be one of oxidation, a slight degree of nitration also occurring. Thus PhNHMe and BuNO<sub>2</sub> formed a red viscous product, while Ph<sub>2</sub>NH and EtNO<sub>2</sub> gave a green amorphous solid. Ph<sub>2</sub>NNO was also formed. Tertiary amines are also oxidized by nitric esters. PhNMe<sub>2</sub> was converted into a violet viscous solid, with evolution of oxides of N. The reactions between PhNMe<sub>2</sub> and the nitric esters of polyhydric alcs. are much more rapid than those between the base and the monohydric alcs. If the relative speeds of decompn. of nitric esters be measured by the colors produced with PhNMe<sub>2</sub>, the speeds of decompn. of Et, Bu, Am, cellulose and mannitol nitrates, when heated for 40 hrs. with PhNMe<sub>2</sub>, are in the ratio 1, 2.85, 0.175, 0.4 and 22.9, resp. PAUL BOONE

**New series of anesthetics. Acylaniline derivatives.** WALTER H. HARTUNG AND

J. C. MUNCH. *J. Am. Chem. Soc.* 51, 2570-4 (1929).—Acylanilines and acyltoluidines have anesthetic properties, particularly their HCl salts, if there is at least a butyrophenone skeleton. The following intermediate  $\text{NO}_2$  derivs. were prepd.: *m*-Nitrovalerophenone,  $b_p$  145-50°; 3-nitro-4-methylphenyl *Pr* ketone, m. 77.5° (semicarbazone, m. 215-6°); *iso-Pr* deriv., m. 41.0; *Bu* deriv., m. 48.0° (semicarbazone, m. 210°); *iso-Bu* deriv., m. 54.5° (semicarbazone, m. 214°). These were reduced to the  $\text{NH}_2$  derivs. *m*-Aminovalerophenone,  $b_p$  160-3° (HCl salt, m. 155.5-6.0°); 3-amino-4-methylphenyl *Et* ketone,  $b_p$  190-5°, m. 85.5-6° (*Ac* deriv., m. 131.5°; HCl salt, m. 204° (decompn.)); *Pr* deriv.,  $b_p$  150-65°, m. 69.0° (*Ac* deriv., m. 130.5°; HCl salt, m. 168°); *iso-Pr* deriv.,  $b_p$  150-3° (HCl salt, m. 167.5°); *Bu* deriv.,  $b_p$  170-85°, m. 61.0° (*Ac* deriv., m. 93-4°; HCl salt, m. 91.5-3.0°); *iso-Bu* deriv.,  $b_p$  165-70° (*Ac* deriv., m. 117.5°; HCl salt, m. 142.5°). Preliminary data are given on the m. l. d. of the HCl salt and the duration of anesthesia when applied to the rabbit cornea. C. J. WEST

Constitution of the normal diazotates and diazo hydrates. A. HANTZSCH. *Ber.* 62B, 1235-41 (1929).—H. cannot agree with Cambi and Szegő (*C. A.* 22, 337) that the normal diazotates are not *syn*-stereoisomers of the *anti*-diazotates but structurally isomeric nitro derivs. C. A. R.

Organic derivatives of silicon. XXXIX. The action of sodium on phenoxychlorosilicane. REGINALD AUBREY THOMPSON AND FREDERICK STANLEY KIPPING. *J. Chem. Soc.* 1929, 1176-9; cf. *C. A.* 23, 2954.—A very few compds. of the type  $\text{R}_2\text{SiCl}$  are known to be converted into derivs. of silicoethane when they are heated with Na (Kipping, *C. A.* 15, 2416) but  $\text{Ph}_2\text{SiCl}_2$  does not yield a deriv. of silicoethylene; the action of Na on  $\text{Ph}_2(\text{PhO})\text{SiCl}$  did not yield the desired product,  $(\text{PhOSiPh})_2$ . It therefore seemed of interest to study the action of Na on various phenoxychlorosilicane.  $\text{PhOH}$  (2.5 mols.) in an approx. equal vol. of  $\text{C}_6\text{H}_6$ , dropped into 1 mol. boiling  $\text{SiCl}_4$  and the mixt. heated at 200° for 3-4 hrs., gives a mixt. of 4 products: *Phenoxytrichlorosilicane*,  $b_{60}$  183-6°, fumes strongly in moist air and readily hydrolyzed by  $\text{H}_2\text{O}$  (about 20% yield); *diphenoxydichlorosilicane*,  $b_{60}$  199.5-202°,  $b_{60}$  215-8°, viscous, fuming liquid (35-40%); *triphenoxychlorosilicane*,  $b_{25}$  235-9°,  $b_{60}$  252-6°, very viscous, fumes only slightly in moist air (about 35%);  $\text{Si}(\text{OPh})_4$ , m. 48° (2-5%). Heated with excess of Na in boiling  $\text{C}_6\text{H}_5\text{Me}_2$ , the Cl derivs. are slowly attacked, giving a dark bluish black deposit; the whole of the Cl is finally eliminated as NaCl. The filtered soln. contains  $\text{Si}(\text{OPh})_4$ , the yield of which shows that practically all of the PhO groups in the original halogen compd. are obtained in the form of the ester. Since the Cl compds., when heated alone, do not undergo any change, some  $\text{PhONa}$  must be formed, which then reacts with the remainder to give the ester. The original insol. material is largely Si, most of which is converted into  $\text{SiO}_2$  or silicoformic acid by the action of  $\text{H}_2\text{O}$ . XL. Attempts to prepare unsaturated compounds from phenylsilicon trichloride. FREDERICK STANLEY KIPPING, ARTHUR GEORGE MURRAY AND JOHN GWILLIAM MALBY. *Ibid* 1180-91.—At the present time there is no evidence of a compd. contg. the group  $\text{Si C}$ ; when dichlorides,  $\text{R}_2\text{SiCl}_2$ , are heated with Na, the products do not contain the complex  $:\text{Si}:\text{Si}:$ , but are either open- or closed-chain structures consisting of  $-\text{SiR}_2-\text{SiR}_2-$  groups. The action of Na upon  $\text{PhSiCl}_3$  under different conditions does not give  $\text{PhSi}:\text{SiPh}$  but a mixt. of very complex products, most of which apparently are satd. compds.  $\text{PhSiCl}_3$ ,  $b_{200}$  152-3°, is easily obtained pure by using 2 mols.  $\text{SiCl}_4$  and 1.5 mols.  $\text{PhMgBr}$  (100 g. from 170 g.  $\text{SiCl}_4$ ). At about 180°, in the absence of a solvent,  $\text{PhSiCl}_3$  and Na slowly but almost quant. give a grayish insol. powder, with 25.1-26.8% Si, which does not react with I or Br and is not attacked by a mixt. of piperidine and aq. alkalis. In boiling  $\text{C}_6\text{H}_6$  or  $\text{PhMe}$ , the action of Na is inappreciable. In boiling  $\text{C}_{10}\text{H}_8$ , the reaction with Na is definitely exothermic and is completed much more rapidly than without a solvent. The proportion of product insol. in org. solvents is small and contains 33.9-34.7% Si and gives 1-1.2 atoms of H per atom Si readily with NaOH. The main product, fractionated from various solvents, gives preps., all of which contain O, while some contain  $\text{SiPh}_2$  groups and possibly  $\text{C}_{10}\text{H}_7$  radicals; various analyses are reported. In boiling  $\text{C}_6\text{H}_6$  at about 150° in a sealed tube or in boiling  $\text{C}_6\text{H}_5\text{Me}_2$ ,  $\text{PhSiCl}_3$  is attacked by Na fairly readily at first but prolonged heating is necessary to complete the reaction; K is therefore added towards the end of the operation in most of the expts. with  $\text{C}_6\text{H}_5\text{Me}_2$ . With either solvent there is only a small proportion of insol. product, similar to that obtained with  $\text{C}_{10}\text{H}_8$ . The sol. matter from the  $\text{C}_6\text{H}_5\text{Me}_2$  solns., prepd. in a N atm., is a pale yellow resin, contg. only a small proportion of unsatd., probably tervalent, Si atoms. Fractionation gives a series of colorless powders and gelatinous products, all of which appear to be complex mixts., which either char without melting or liquefy over a wide range of temp. The more sol. ones contain  $\text{SiPh}_2$  groups. Analyses of the freshly prepd., unfractionated sol.

material indicates the presence of at least 4% O; a further quantity of O is absorbed at 120°, the material becoming much less sol., but its glue-like character at that temp. prevents very accurate detns.; it does not seem to oxidize in the air at room temp. The source of the O in the unexposed products has not been ascertained. The results of many analyses seem to show that the more sparingly sol. fractions are composed principally of compds. contg. oxidized SiPh groups, whereas the components of the more sol. fractions contain in addn. a considerable proportion of SiPh<sub>2</sub> groups. F p detns. in C<sub>6</sub>H<sub>6</sub> and camphor show that the av. mol. wt. of the components of the more sparingly sol. fractions is about 5000, that of the substances in the most sol. material being about 900. The crude product, therefore, seems to be mixts. of compds. contg. from about 6 to at least 50 Si atoms in their mols. All the fractions are attacked by aq. piperidine and by aq. alkalis in the presence of an org. solvent, with evolution of H and fission of Si-Si linkages. The only fission product isolated was Ph<sub>2</sub>Si(OH)<sub>2</sub>, the difficulties of the identification of the products of fission are pointed out. The results indicate that under all the different exptl. conditions the PhSiCl<sub>3</sub> is converted into a complex mixt. of products, the components of which contain not only SiPh and SiPh<sub>2</sub> groups but also Si atoms uncombined with C; some of the Si atoms seem to be unsatd., probably tervalent, but most of them have become satd. by combination with O. The mechanism of the reaction is discussed. C. J. WEST

**New observations upon improved active magnesium-copper alloys for the preparation of the Grignard reagent.** HENRY GILMAN AND LLOYD L. HECK. *Bull. soc. chim.* **45**, 250-4(1929); cf. C. A. **22**, 1134.—A series of Mg-Cd alloys varying in compn. from 0 to 19.6% Cu to be used in the prepn. of the Grignard reagent was studied. Several of these were found superior to Baeyer's active Mg. An alloy with 14.5% Cu was found to be most active of those investigated. ROBERT F. MEHL

**The Grignard reagents prepared from *p*-dibromobenzene.** HENRY GILMAN, N. J. BEABER AND H. L. JONES. *Rec. trav. chim.* **48**, 597-602(1929).—In general polyhalogen aromatic compds. undergo a reaction with Mg, which is almost exclusively confined to the prepn. of a mono-organomagnesium halide. Particular exceptions have been noted with some poly-I compds. where varying quantities of polyorgano magnesium iodides form (Votocek and Kohler, C. A. **8**, 2385; Thomas, C. A. **19**, 3085; Bruhat and Thomas, C. A. **20**, 3451). The reaction between *p*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub> and Mg in ether is, however, according to the results of previous investigators, confined to one of the Br atoms, the formation of *p*-C<sub>6</sub>H<sub>4</sub>(MgBr) being only reported in a few cases. Houben (*Ber.* **38**, 3796(1905)) obtained a 1.25% yield of *p*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> by adding CO<sub>2</sub> to the Grignard reagent, prep'd from *p*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>, whereas Pink (C. A. **18**, 669) states that the di-Grignard reagent is only formed in traces. On refluxing *p*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub> with an excess of Mg for 12 hours and subsequent hydrolysis Quelet (C. A. **22**, 231, 23, 2157) obtained 12% of benzene, 70% of PhBr and 10% of (*p*-BrC<sub>6</sub>H<sub>4</sub>)<sub>2</sub>. The present authors have found that under ordinary conditions there is no evidence of the appreciable formation of *p*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> from CO<sub>2</sub> when no catalyst is used in the Grignard reaction. With 15-mesh Mg and no catalyst but with extended refluxing in an ether-benzene mixt. the apparent (see below) yield of C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> was 4.2%. On using the highly active 12.75% Cu-Mg alloy of G. Peterson and Schulze (C. A. **22**, 1134), it was possible to get an apparent yield of 23.5% of C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> as follows. The Grignard reaction was allowed to take place between 28.8 g. (0.8 atom) of the freshly reactivated alloy and 23.6 g. of C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub> (0.1 mole) in 200 cc. ether; when the reaction was over, the greater part of the ether was distd. off and replaced by benzene and the mixt. refluxed for 6 hrs. After the reaction with CO<sub>2</sub> according to the method of G. and Parker (C. A. **19**, 467) the crude mixt. of acids was collected in the usual way, dried and extd. with CHCl<sub>3</sub> in order to remove *p*-BrC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H as well as any phenolic compds. that might have been present. The yield of C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> was 23.5%, but this acid gave a Na fusion test for Br while the neutralization value indicated only a yield of 7.7% of C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>, assuming that the contaminant was *p*-BrC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H. By assuming the intermediate formation of free radicals and of MgX the possibility exists that several transformation products are formed from the *p*-BrC<sub>6</sub>H<sub>4</sub> radical (cf. G. and Kirby, C. A. **23**, 2953) so that a large no. of Grignard reagents may be formed. A development of this type is helpful in understanding the fact that the C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> is not pure but contains other acids to a lesser extent. C. F. VAN DUIN

**Nitro- and halonitrobenzenesulfonic acids.** J. N. FLIGERSMA. *Rec. trav. chim.* **48**, 752-64(1929).—Several nitro- and halonitrobenzenesulfonic acids have been prep'd in a pure condition, viz., free from isomers, according to the method of Blankensma (*Ver. slag. Akad. Wetenschappen Amsterdam* **8**, 299(1899); **9**, 401(1900); *Rec. trav. chim.* **19**, 111(1900); **20**, 121(1901)) by replacement of a mobile halogen atom or a mobile

nitro group in a (halo-)nitrobenzene by S by means of Na polysulfide and subsequent oxidation of the disulfide to the corresponding (halo-) nitrobenzenesulfonic acid by means of fuming  $\text{HNO}_3$ . The following compds. are described: *2,2'-dinitrodiphenyl disulfide*, m.  $195^\circ$ ; *2-nitrobenzenesulfonic acid*; *4,4'-dinitrodiphenyl disulfide*, for which the m. ps.  $170^\circ$  and  $181^\circ$  are given in the literature and which shows a characteristic transition point at  $134^\circ$  (Blanksma, *Rec. trav. chim.* **20**, 128(1901)) which is denoted by the sudden disruption of the crystals (cf. Leuckart, *J. prakt. Chem.* (2) **41**, 199 (1890)); Zincke, *C. A.* **7**, 3746; Willgerodt, *Ber.* **18**, 331(1885); Kehraman and Bauer, *Ber.* **29**, 2366(1896); Ekbohm, *Ber.* **35**, 655(1902); Fromm and Wittman, *C. A.* **2**, 2932; Bamberger and Kraus, *Ber.* **29**, 282(1896); Fries and Schürmann, *C. A.* **8**, 2382; Chalenger and Collins, *C. A.* **18**, 2689). It is now shown by E that this disulfide exists in 2 forms: 36 g. of crude disulfide, m.  $155-66^\circ$ , was extd. with 80 cc boiling alc., which is far too small an amt. to dissolve the whole mass. The residue, 32 g., m.  $176-8^\circ$  and was extd. with boiling  $\text{AcOH}$ ; the residue, 1 g., m.  $181^\circ$ , while the  $\text{AcOH}$  soln. on cooling deposited colorless crystals, m.  $170^\circ$ . Both substances retained the same m. p. after recrystn. from  $\text{EtOH}$  and both showed the characteristic transition point noted by Blanksma. *4-Nitrobenzenesulfonic acid*; *2,2',4,4'-tetranitrodiphenyl disulfide*, m.  $280^\circ$ ; *2,4-dinitrobenzenesulfonic acid*,  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{SO}_3\text{H} \cdot 3\text{H}_2\text{O}$ , non-hygroscopic needles, m.  $108^\circ$ ; *2,2'-dinitro-4,4'-dichlorodiphenyl disulfide*, m.  $212.8^\circ$ ; *2-nitro-4-chlorobenzenesulfonic acid*, m.  $114-5^\circ$  in the anhyd. state; aniline salt, m.  $207^\circ$ ; this salt is formed on heating the  $\text{SO}_3\text{H}$  acid with aniline at  $185^\circ$ , the  $\text{SO}_3\text{H}$  group being not replaced by the  $\text{NHPh}$  group in this way as in  $2,4-(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{SO}_3\text{H}$ . The constitution of this acid was proved by reduction with Zn dust to *2-amino-4-chlorobenzenesulfonic acid*, leaflets with a sweet taste, which, on treatment with Br water, passes into *2,4,6-tribromo-3-chloroaniline*, m.  $123-4^\circ$ . *2,2'-Dinitro-5,5'-dichlorodiphenyl disulfide*, m.  $171-2^\circ$ ; *2-nitro-5-chlorobenzenesulfonic acid*. *3-Nitro-6-chlorobenzenesulfonic acid* was obtained from Schuchardt and on recrystn. from water m.  $169^\circ$  and contains  $\text{H}_2\text{O}$ ; the structure was proved as follows: (a) on boiling the acid with alkali it was converted into  $6,3\text{-HO}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SO}_3\text{H}$ , which, on treatment with Br water, yields  $2,6,4\text{-Br}_2(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{OH}$ , m.  $145^\circ$ ; (b) the acid was converted by means of alc.  $\text{NH}_3$  at  $130^\circ$  into the  $\text{NH}_4$  salt of  $3,6\text{-O}_2\text{N}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{SO}_3\text{H}$ , which, on treatment with 2 moles  $\text{NaNO}_2$  and boiling with  $\text{EtOH}$ , gave  $m\text{-O}_2\text{NC}_6\text{H}_4\text{SO}_3\text{H}$  (chloride, m.  $61.5^\circ$ ), while on treatment with Br water  $2,6,4\text{-Br}_2(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{NH}_2$ , m.  $206^\circ$ , was obtained. *2,2'-Dinitro-4,4'-dibromodiphenyl disulfide*, m.  $174^\circ$ ; *2-nitro-4-bromobenzenesulfonic acid*, which, after standing over  $\text{P}_2\text{O}_5$  for 14 days still contains 1 mole  $\text{H}_2\text{O}$ , m.  $120^\circ$ .

C. F. VAN DUIN

The preparation and solubility in water of some salts of the nitro- and halonitrobenzenesulfonic acids. J. N. ELGERSMA. *Rec. trav. chim.* **48**, 765-9(1929); cf. preceding abstract.—The results are given in the following tables:

I Water of crystn.

	Cs	Rb	K	Na	$\text{NH}_4$	$\text{Li}$
2 Nitrobenzenesulfonic acid	0	0	0	..	..	..
3-Nitrobenzenesulfonic acid	0	0	0	..	..	..
4-Nitrobenzenesulfonic acid	0	0	1	..	..	..
2,4-Dinitrobenzenesulfonic acid	1	$3\frac{1}{2}$	0	..	..	..
2-Nitro-4-chlorobenzenesulfonic acid	0	0	0	0	..	1
2-Nitro-5-chlorobenzenesulfonic acid	0	0	0	..	..	..
3-Nitro-6-chlorobenzenesulfonic acid	0	0	0	1	1	..
2 Nitro-4-bromobenzenesulfonic acid	0	0	0	1	..	..

II Soly. at  $25^\circ$  (the figures give the amt. of anhyd. salt dissolving at  $25^\circ$  in 100 g. of water)

	Cs	Rb	K
2-Nitrobenzenesulfonic acid	20.74	16.08	9.63
3-Nitrobenzenesulfonic acid	37	6.09	3.04
4 Nitrobenzenesulfonic acid	5.46	5.80	5.95
2,4-Dinitrobenzenesulfonic acid	2.50	3.90	4.70
2-Nitro-4-chlorobenzenesulfonic acid	6.98	1.93	0.87
2-Nitro-5-chlorobenzenesulfonic acid	2.25	1.07	1.59
3-Nitro-6-chlorobenzenesulfonic acid	1.51	1.32	2.83
2-Nitro-4-bromobenzenesulfonic acid	6.09	1.80	1.68

Of all the K salts investigated, that of  $4,2\text{-Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{SO}_3\text{H}$  appeared to be most sparingly sol. and it was found that in a diln. 1:300 K may be detected with certainty,

brilliant crystals being formed in the course of 4 min. Thus this acid may be used as a qual. reagent for K. From the 2nd table it follows that the introduction of a  $\text{NO}_2$  group in  $\text{PhSO}_3\text{H}$  decreases the soly. of the Cs, Rb and K salts, the further introduction of a halogen atom or a  $\text{NO}_2$  group causing a further decrease in the soly. independent of the position of the groups in the benzene ring. A relation between structure and soly. cannot be traced.

C. F. VAN DUIN

**Nitro- and halonitrobenzenesulfonic acids. III.** J. N. ELGERSMA. *Rec. trav. chim.* 48, 770-7(1929); cf. preceding abstrs.—The equiv. cond. in  $\text{H}_2\text{O}$  at various dilns. as also the equiv. cond. at infinite diln. was measured for 2-nitro-, 3-nitro-, 4-nitro-, 2,4-dinitro-, 2-nitro-4-chloro-, 2-nitro-5-chloro-, 3-nitro-6-chloro- and 2-nitro-4-bromobenzenesulfonic acids and some of their salts. The value for  $\lambda_\infty$  varies for all these acids only between the values 376 and 378, while the measurements of the cond. of the K salts of 2- and 3- $\text{O}_2\text{NC}_6\text{H}_4\text{SO}_3\text{H}$  as well as of the Na salt of the 2-nitro-4-chloro acid are in harmony with those of the acids itself. In practice the values of  $\lambda_\infty$  are the same for all the acids investigated, even for the non-isomeric ones. The rule of Ostwald (*Z. physik. Chem.* 2, 850(1888)), that  $\lambda$  is equal for isomeric ions, is thus confirmed, and the values found for  $\lambda_\infty$  are in agreement with the rules of Walden (*Das Leitvermögen der Lösungen*, II, 130(1924)) and of Rimbach (*Kleines physikalisch-chemisches Praktikum*, 84(1921)) but not with the rule of Ostwald-Luther (*Physiko-chemische Messungen* 481 (1910)). From the degree of dissoen. calcd. from these measurements, it follows that the acids investigated belong to the strong acids and in this respect are comparable with the strong inorg. acids. When 1 mole is dissolved in 16 l. water, the degree of dissoen. is about 93%, except for 2,4- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{SO}_3\text{H}$ , the strongest of the acids used, which is practically completely split up into its ions in this diln. For all the figures detd. experimentally as well as for details the original paper must be consulted.

C. F. VAN DUIN

The reaction between phenylmagnesium bromide and some amides of sulfonic, sulfinic and sulfenic acids. HENRY GILMAN AND C. C. VERNON. *Rec. trav. chim.* 48, 745-7(1929).—Under ordinary conditions, viz., in ether soln. at room temp., there is no appreciable reaction between *p*-toluenesulfonyldiphenylamine, di-*p*-toluenesulfimide, benzenesulfanilide and benzenesulfonyldiethylamine with  $\text{PhMgBr}$ . Except in the latter case a reaction was not observed when the reaction was carried out at higher temps. in ether-toluene mixts. Benzenesulfonyldiethylamine, however, reacted under these forced conditions with the formation of  $\text{Ph}_2\text{S}$  and  $\text{NH}_4\text{Et}_2$ .

C. F. VAN DUIN

**Syntheses in the diphenyl ether series. I. Preparation of some simple derivatives.** C. M. SUTER. *J. Am. Chem. Soc.* 51, 2581-5(1929).—In the nitration of  $\text{Ph}_2\text{O}$  best results were obtained by using 100 cc. fuming  $\text{HNO}_3$  (d. 1.52) in 300 cc. glacial  $\text{AcOH}$ , added over a period of 2 hrs., to a well-stirred soln. of 340 g.  $\text{Ph}_2\text{O}$  in 400 cc.  $\text{Ac}_2\text{O}$  at 25-30° and pouring the mixt. into  $\text{H}_2\text{O}$  after 3.5 hrs.; 370 g. or 80% of the mono- and di- $\text{NO}_2$  derivs. were obtained, the first  $b_{14}$  193-210°, 700 g. of the mono- $\text{NO}_2$  mixt. at 0° deposited 270 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{OPh}$ ; the remaining oil contained about 25% of the *p*-isomer, so that the original mixt. contained 54% of the *p*-deriv., m. 57°, yields under various conditions are reported. Reduction with Zn and  $\text{CaCl}_2$  in  $\text{H}_2\text{O}$  gives the *p*- $\text{NH}_2$  deriv.,  $b_{14}$  187-9° (cor.). The mixt. of  $\text{NO}_2$  compds., on reduction, gives 54% *o*- and 21% *p*- $\text{NH}_2$  derivs., the latter being pptd. as the sulfate; the *o*- $\text{NH}_2$  deriv.,  $b_{14}$  172-3° (cor.), m. 44-5° (*Ac* deriv., m. 81°). *p*-Cyanodiphenyl ether, from the *p*- $\text{NH}_2$  deriv. through the diazo reaction,  $b_{14}$  187-8° (cor.), m. 47°; the *o*- $\text{CN}$  deriv.  $b_{14}$  188° (cor.). *p*-Bromo-*p*-aminodiphenyl ether, by reduction of the  $\text{NO}_2$  deriv. with Fe and HCl, m. 109° (84% yield); *Ac* deriv., m. 162-3° (cor.). A Br atom in 1 ring of  $\text{Ph}_2\text{O}$  affects only slightly substitution in the 2nd ring, which is in contrast to the influence of the  $\text{NO}_2$  group.

C. J. WEST

**Conjugated systems. I. Chlorination of phenylbutadiene.** IRVING E. MUSKAY AND K. A. HUGGINS. *J. Am. Chem. Soc.* 51, 2496-502(1929).—Chlorination of  $\text{PhCH=CHCH=CH}_2$  gives the 3,4-*di*-Cl deriv. (I),  $b_s$  125°; the structure of I was detd. by the decompn. of the ozonide, the acid portion giving  $\text{BzOH}$ , the aldehyde,  $\text{BzH}$ . I is further chlorinated in  $\text{CHCl}_3$  to a *tetra*-Cl deriv., which is a mixt. of stereoisomers,  $b_s$  155-66°, partially reduced by Zn to I and completely reduced to  $\text{PhCH}_2\text{CHCH}_2\text{CH}_2$ . Heating I with aq. KOH at 90° for several hrs. gives nearly quant. 1-phenyl-4-chlorobutadiene (II),  $b_s$  115.5°, m. 53°, also obtained in 60% yield by refluxing I for several hrs. The structure of II was established by hydrolysis and oxidation to  $\text{PhCH}_2\text{CHCH}_2\text{CO}_2\text{H}$ . II absorbs 1 mol. Cl, giving 1-phenyl-4-chloro- $\Delta^1$ -butene 3,4-dichloride (1-phenyl-3,4,4'-trichlorobutene),  $b_s$  140°, whose structure was proved by ozonization; excess Cl gives 1-phenyl-1,2,3,4,4'-pentachlorobutane,  $b_s$  162°. Straus' work (*C. A.* 3,

2697) on the bromination of  $\text{PhCH:CHCH:CH}_2$  was confirmed in every particular.

C. J. WEST

**Mobility of symmetrical triad prototropic systems. V. A new triad system (methylenazomethine).** CHRISTOPHER KELK INGOLD and CHARLES WM. SHOPPE. *J. Chem. Soc.* 1929, 1199–204; cf. *C. A.* 23, 2958.—The present position relating to the study of mobile H tautomerism (prototropy) is summarized, the principles of which are applied to a new triad prototropic system, termed the "methylenazomethine" system,  $\text{CHN:C} \rightleftharpoons \text{C:NCH}$ . *p*- $\text{MeOC}_6\text{H}_4\text{CHO}$  and  $\text{PhCH}_2\text{NH}_2$ , heated at  $100^\circ$  for 0.5 hr. in H, give *p*-methoxybenzylidenebenzylamine (I), m.  $42^\circ$ . Hydrolysis with 2 N  $\text{H}_2\text{SO}_4$  by boiling 0.5 hr. gives the 2 components. The *picrate*, m.  $198^\circ$  (decompn.).  $\text{BzH}$  and *p*- $\text{MeOC}_6\text{H}_4\text{CH}_2\text{NH}_2$  give benzylidene-*p*-methoxybenzylamine (II),  $b_{17}$   $217^\circ$ ; *picrate*, m.  $188^\circ$  (decompn.); *benzoate*, m.  $135^\circ$ . Hydrolysis gives the 2 components. Either I or II, heated 2 hrs. with 30 parts 1.45 N  $\text{EtOH-EtONa}$  at  $85^\circ$ , gives a mixt. consisting of 21.1% II and 78.9% I.  $\text{PhCH}_2\text{N:CH}_2$ , in  $48^\circ$ , is stable to boiling 2.92 N  $\text{EtOH-EtONa}$  and is hydrolyzed by hot 2 N  $\text{H}_2\text{SO}_4$  to  $\text{HCHO}$  and  $\text{PhCH}_2\text{NH}_2$ . Fusion with KOH at  $300^\circ$  or heating with 1.45 N  $\text{EtOH-EtONa}$  at  $190^\circ$  for 7 hrs. causes partial conversion into  $\text{PhCH:NMe}$  (III). However, III is not converted into the tautomer under similar conditions.

C. J. WEST

**Reduction with alcohols of cinnamaldehyde to  $\beta$ -phenylpropionaldehyde.** PAUL F. WESTON and HOMER ADKINS. *J. Am. Chem. Soc.* 51, 2589 (1929).—By the method of reducing  $\text{CH}_2\text{:CHCHO}$  described in *C. A.* 22, 3132, 100 g.  $\text{PhCH:CHCHO}$  gives about 55 g. unchanged aldehyde, 20 g.  $\text{PhCH}_2\text{CH}_2\text{CHO}$  and 15 g. of a dark brown, viscous liquid b. above  $250^\circ$ ; thus, about 35% of the aldehyde reacted and 60% of the part reacting is converted into  $\text{PhCH}_2\text{CH}_2\text{CHO}$ ; about 50% of the alc. was used in the formation of  $\text{EtCHO}$  and  $\text{PhCH}_2\text{CH}_2\text{CHO}$  while most of the remainder forms  $\text{Pr}_2\text{O}$ . Similar reactions occurred and approx. the same yields of  $\text{PhCH}_2\text{CH}_2\text{CHO}$  were obtained from 50 g.  $\text{PhCH:CHCHO}$  in 100 cc.  $\text{MeOH}$ ,  $\text{EtOH}$  or  $\text{PrOH}$ . C. J. W.

**Question of the tautomerism of *o*-nitro compounds.** F. ARNDT. *Ber.* 62B, 1167–71 (1929).—Reply to Tanasescu (*C. A.* 23, 1126).

C. A. R.

**$\beta$ -Phenylisobutyl methyl ketone and its derivatives. Synthesis of  $\alpha$ - and  $\beta$ -phenylisovaleric acids.** ALFRED HOFFMAN. *J. Am. Chem. Soc.* 51, 2542–7 (1929).— $\text{Me}_2\text{C:CHAc}$ ,  $\text{C}_6\text{H}_5$  and  $\text{AlCl}_3$  give about 80% of  $\beta$ -phenylisobutyl Me ketone (I),  $b_{22}$   $134^\circ$ ,  $b_{700}$   $252^\circ$  (cor.),  $d_{25}^{20}$  0.972; *semicarbazone*, m.  $163\text{--}4^\circ$ ; *oxime*, m.  $52\text{--}4^\circ$ ; *tetra-Br deriv.*, m.  $96\text{--}8^\circ$ . I and  $\text{ZnCl}_2$  at  $180^\circ$  give a mixt. of hydrocarbons, from which the *compd.*  $\text{C}_{21}\text{H}_{24}$ ,  $b_{18}$   $195^\circ$ , m.  $130.5\text{--}1^\circ$  (cor.), is obtained from the fraction,  $b_{18}$   $150\text{--}230^\circ$ ; it does not react with Br but yields a *tri-NO}\_2* deriv., m.  $180\text{--}4^\circ$ . Reduction of I gives  $\beta$ -phenylisobutylmethylcarbinol,  $b_{17}$   $132\text{--}3^\circ$ ,  $d_{25}^{20}$  0.960, dehydrated by  $\text{ZnCl}_2$  to the hydrocarbon  $\text{C}_{12}\text{H}_{16}$  (probably  $\text{Me}_2\text{PhCCH:CHMe}$ ),  $b_{17}$   $96\text{--}8^\circ$ ,  $d_{25}^{20}$  0.889; Br reacts instantly; oxidation with  $\text{CrO}_3$  gives a complex mixt. of ketones. Oxidation of I with  $\text{NaBrO}$  gives  $\beta$ -phenylisovaleric acid, m.  $58\text{--}8.5^\circ$ ; *Me ester*,  $b_{11}$   $120^\circ$ , anilide, m.  $122\text{--}3^\circ$ ; *NO}\_2* deriv., m.  $169\text{--}72^\circ$ . This was synthesized from  $\text{PhMe}_2\text{CCl}$  and  $\text{CH}_2(\text{CO}_2\text{Et})_2$ , the resulting product being hydrolyzed and then heated at  $200^\circ$  until  $\text{CO}_2$  evolution ceased. The  $\alpha$ -acid was similarly prepd from  $\text{PhCH}(\text{CO}_2\text{Et})_2$  and  $\text{Me}_2\text{CHI}$ , and  $b_{14}$   $159\text{--}60^\circ$ , m.  $60^\circ$ , .1g salt; *anilide*, m.  $132\text{--}3^\circ$ . These results show that the acid obtained by oxidation of the product from  $\text{C}_6\text{H}_5$ ,  $\text{Me}_2\text{C:CHCO}_2\text{H}$  and  $\text{AlCl}_3$  (Rijkman) is the  $\beta$ - and not the  $\alpha$  acid, as he assumed.

C. J. WEST

**Formation of bases from carbonyl compounds. III. A synthesis of *dl*-ephedrine and other amino alcohols.** A. SKITA and F. KEIL (in part with L. BOENTE). *Ber.* 62B, 1142–51 (1929); cf. *C. A.* 23, 111.—In the earlier paper the conversion of  $\text{CH}_2\text{Ac}_2$  in the presence of cyclohexylamine into  $\text{MeCH(OH)CH}_2\text{CH(NHC}_6\text{H}_{11})\text{Me}$  was described as an example of the transformation of diketones into  $\text{NH}_2$  alcs. by catalytic reduction in basic soln. Some time later Manske and Johnson reported the synthesis of *dl*-ephedrine,  $\text{PhCH(OH)CH(NHMe)Me}$  (I), from  $\text{AcBz}$  in  $\text{MeNH}_2$  (*C. A.* 23, 1404). They ascribe the entrance of the  $\text{MeNH}$  group next to the alkyl group to the peculiar influence of the Ph residue, but it has been established that in all unsym. diketones, even the purely aliphatic 1,2-, 1,3- and 1,4-diketones, the keto group next to the smaller radical has the greater power of condensation, so that aryl alkyl 1,2-diketones like  $\text{AcBz}$  occupy no special position in this respect. Moreover, with their Pt oxide or Pt sponge catalyst M. and J. obtained only 25–40% yields of I while the authors with their method (colloidal Pt) were able to convert 0.1 g. mol. of  $\text{AcBz}$  into I within an hr. and to isolate 50% of pure I; because of the appearance of M. and J.'s paper they therefore feel impelled to describe a few more examples of the application of their method sooner than they had intended.  $(\text{CH}_3\text{Ac})_2$  reduced in the presence of  $\text{C}_6\text{H}_{11}\text{NH}_2$  gave

on the 1 hand 5-cyclohexylamino-2-hexanol (II) and on the other hand a *N*-cyclohexyl-2,5-dimethylpyrrolidine (III), formed by reaction of the  $(\text{CH}_3\text{Ac})_2$  with the  $\text{C}_6\text{H}_{11}\text{NH}_2$  with elimination of  $\text{H}_2\text{O}$ , and reduction of the resulting pyrrole deriv.  $\text{MeCHAc}_2$  gave only 1 product, 4-cyclohexylamino-3-methyl-2-pentanol (IV), but  $\text{BzCH}_2\text{Ac}$  in the presence of  $\text{MeNH}_2$  gave a mixt. of 2 diastereomeric 1-phenyl-3-methylamino-1-butanols (V and VI) sepd. through their picrates.  $\text{Bz}_2$  in the presence of  $\text{MeNH}_2$  gave 1,2-diphenyl-2-methylamino-1-ethanol (VII) and  $\text{MeCOPr}$  yielded 2-methylamino-3-hexanol (VIII) and a pyrrolidine deriv. (IX) formed by the action of  $\text{MeNH}_2$  on the  $\text{PrCOMe}(\text{OH})$ .  $\text{CH}_3\text{COAc}$  produced from the  $\text{PrCOMe}$  in basic soln., and subsequent reduction of the resulting pyrrole deriv. The I obtained by this method contained no pseudophedrine. Catalytic reduction of I in the presence of  $\text{HCHO}$  gave the tertiary *dl*-*N*-methylphedrine (X). These tertiary bases can also be obtained directly from the diketones in the presence of secondary bases; thus,  $\text{CH}_2\text{Ac}_2$  in  $\text{NHMe}_2$  gave 4-*N*-dimethylamino-2-pentanol (XI). II (2 g. from 13.7 g.  $(\text{CH}_3\text{Ac})_2$ ),  $b_{21}$  153°, m. 76-7°; *picrate*, m. 150-1° III (6 g.),  $b_{16}$  100°,  $d_4^{20}$  0.8927,  $n$  1.47067, 1.47339, 1.47973 for  $\alpha$ , D and  $\beta$  at 20°,  $E_D$  -0.14, -0.13, -0.15, 3% for  $\alpha$ , D,  $\beta$  and  $\beta - \alpha$ , gives the pyrrole pine-splinter reaction after rapid heating in a test tube; *picrate*, light yellow, m. 111-4°. IV,  $b_1$  104° ... H; *picrate*, m. 157-9°. V,  $b_{16}$  155-6°,  $d_4^{20}$  1.0101°  $n$  1.52032, 1.52421, 1.53443 for  $\alpha$ , D and  $\beta$  at 20.5°,  $E_D$  -0.17, -0.17, -0.14, 4% for  $\alpha$ , D,  $\beta$  and  $\beta - \alpha$ ; *picrate*, light yellow, m. 193-4°. VI,  $b_{16}$  155-6°,  $d_4^{20}$  1.0079,  $n$  1.51902, 1.52298, 1.53331,  $E_D$  0.15, -0.15, -0.12, 4%; *picrate*, dark yellow, m. 118-9°. "Oxidizing" actions of alkalis. II. Aromatic hydroxy aldehydes. GUNTHER Lock. *Ber.* 62B, 1177 88(1929); cf. C. A. 23, 827.—Like *o*- $\text{HOC}_6\text{H}_4\text{CHO}$ , the *m* and *p*-comps. on fusion with  $\text{KOH}$  decomp. almost quantitatively into  $\text{H}_2$  and  $\text{KOC}_6\text{H}_4\text{CO}_2\text{K}$ , but while the *o*- and *p*-comps. begin to evolve  $\text{H}$  below 110°, the *m* compd. (I) begins to react only at about 190°, and moreover the yellow color which is produced when the aldehyde is mixed with the powd.  $\text{KOH}$  gradually disappears without any external heating. The cause of these phenomena is that I undergoes the Cannizzaro reaction with solid  $\text{KOH}$  or its soln. at room temp. and at 190° the  $\text{KOH}$  further reacts with the *m*- $\text{HOC}_6\text{H}_4\text{CH}_2\text{OH}$  resulting from the disproportionation. The gradual disappearance of the yellow color at room temp. marks the 1st reaction, the yellow phenolate changing into the colorless salts of  $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$  and  $\text{HOC}_6\text{H}_4\text{CH}_2\text{OH}$ . The old rule that a phenolic  $\text{HO}$  group prevents the disproportionation into alc and acid holds, therefore, only when the  $\text{HO}$  group is in the *o*- or *p*-position to the  $\text{CHO}$  group. With aq.  $\text{KOH}$  I reacts at room temp. without evolution of gas and gives more than 90% of the acid and alc. In parallel expts. with I and  $\text{KOH}$  on the 1 hand and the alc. and  $\text{KOH}$  on the other, to det. whether a Cannizzaro reaction precedes the evolution of  $\text{H}$ , the evolution of  $\text{H}$  in both cases began at 190°, showing that it is produced from the alc. The 6-Br deriv. of I reacts visibly more sluggishly with 50%  $\text{KOH}$ , the mixt. must be slightly warmed but the end result is the same as with I itself. The 4- and 6- $\text{NO}_2$  derivs. likewise do not undergo the Cannizzaro reaction as readily as I, giving 38-9 and 70%, resp., of the corresponding alc. The 4-nitro-3-hydroxybenzyl alc. (II) so obtained m. 97° but depresses about 30° the m. p. of the 3,4-isomer, likewise m. 97°, obtained by Stoermer by introducing the  $\text{CH}_2\text{OH}$  group into *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ . There are conflicting data in the literature as to whether or not *p*- $\text{HOC}_6\text{H}_4\text{CHO}$  (III) changes into the alc. and acid with alkalis at room temp.; L. finds that it undergoes no change when allowed to stand 5 weeks, protected from the air, in excess of 50%  $\text{KOH}$ ; on fusion it begins to evolve  $\text{H}$  at about 110° while the alc. does not react below 165°. 3,4-( $\text{HO}$ ) $_2\text{C}_6\text{H}_3\text{CHO}$  (IV) behaves quite like III both on fusion with  $\text{KOH}$  and with 50%  $\text{KOH}$  at room temp. Since the *p*- $\text{HO}$  group in IV prevents the Cannizzaro reaction, its 2 Me ethers, vanillin (V) and isovanillin (VI) should, and as a matter of fact do, behave differently. V is unchanged at room temp. but on fusion evolves  $\text{H}$  at 110° and gives a mixt. of 3,4-( $\text{HO}$ ) $_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$  and about 24% 4,3- $\text{HO}(\text{MeO})\text{C}_6\text{H}_3\text{CO}_2\text{H}$  after 3 hrs. at 150-210°, while VI is converted into the alc. and acid and does not evolve  $\text{H}$  below about 190°. 6-Bromo-3-hydroxybenzyl alc. (yield, 70%), m. 142°, has a burning taste and causes sneezing, gives a blue-violet color with aq.  $\text{FeCl}_3$ , a yellowish color with alkalis, a flocculent ppt. with  $\text{Br}$  water, does not react with  $\text{NH}_3\text{-AgNO}_3$ , dis-

solves in concd.  $\text{H}_2\text{SO}_4$  without color. *6-Nitro compd.*, m.  $120.5^\circ$ , forms a yellow aq. soln. turned intensely yellow by alkalis, gives a red-violet color with  $\text{FeCl}_3$ , forms an intensely S-yellow salt with basic Pb acetate, does not react with  $\text{NH}_3\cdot\text{AgNO}_3$ , dissolves in concd.  $\text{H}_2\text{SO}_4$  with yellow color. II is cream-yellow while Stoermer's compd. is green-yellow; otherwise the 2 isomers greatly resemble each other; both form green-yellow aq. solns., give no characteristic color with  $\text{FeCl}_3$ , form red-yellow solns. with aq. alkalis, do not react with  $\text{NH}_3\cdot\text{AgNO}_3$ , even on boiling, form almost colorless ppts. with Br water; with concd.  $\text{H}_2\text{SO}_4$  II forms a deep red soln. and with aq.  $\text{Pb}(\text{OAc})_2$  yields a cinnabar-red ppt. while the S. compd. dissolves in  $\text{H}_2\text{SO}_4$  with yellow color and forms a reddish yellow Pb salt. *Isovanillyl alc.* (yield, 80%), m.  $132^\circ$ , gives a green color with  $\text{FeCl}_3$ , dissolves in  $\text{H}_2\text{SO}_4$  with Bordeaux-red color. C. A. R.

Optically active isomers of *N*-phenyl- $\beta$ -methylglycineamide-*p*-arsonic acid and their use in the resolution of ephedrine. E. FOURNEAU AND V. NICOLITCH. *Bull. soc. chim.* **43**, 1232-64 (1928).— $\text{MeCHBrCONH}_2$  and  $p\text{-NH}_2\text{C}_6\text{H}_4\text{AsO}_3\text{HNa}$  give 74% *N*-phenyl- $\beta$ -methylglycineamide-*p*-arsonic acid (I). By the use of quinine (strychnine or quinine is unsatisfactory) I is resolved into the *l*-acid (less sol. quinine salt),  $[\alpha]_D^{20} -15.50^\circ$ , and *d*-acid,  $[\alpha]_D^{20} 16.6^\circ$ . Both of these forms of I may be used to resolve ephedrine.  $\alpha$ -Bromopropionylaminophenyl-*p*-arsonic acid is prepd. from  $\text{MeCHBrCOBr}$  and  $p\text{-NH}_2\text{C}_6\text{H}_4\text{AsO}_3\text{H}_2$  (II) in 70% yield. Hydrolysis of  $p\text{-NO}_2\text{C}_6\text{H}_4\text{CH}_2\text{CN}$  with  $\text{H}_2\text{SO}_4$  gives 65%  $p\text{-NO}_2\text{C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H}$  (III), m.  $149.5^\circ$ . The acid chloride of III and Br give the corresponding bromoacetyl chloride or bromide, which with  $\text{NH}_3$  gives  $p\text{-NO}_2\text{C}_6\text{H}_4\text{CHBrCONH}_2$  (IV), m.  $148^\circ$ . Condensation of IV with II gives  $\alpha,\alpha\text{-di-}p\text{-nitrophenylsuccinamide}$ , m.  $212^\circ$ .  $\text{PhCHBrCONH}_2$  and II give 56% phenylglycineamide-*p*-arsonic acid (V). Attempts to resolve V by means of quinine were unsuccessful. Br and  $\text{EtCOCl}$  at  $80^\circ$  give  $\text{MeCHBrCOBr}$ , b.  $153\text{--}5^\circ$ . Other bromides prepd. were:  $\text{Et}_2\text{CHCOBr}$ , b.  $153\text{--}8^\circ$ ;  $\text{Et}_2\text{CBrCOBr}$ , b.  $98\text{--}100^\circ$ ;  $\alpha$ -bromoisovaleryl, b.  $90^\circ$ ;  $\alpha$ -bromoheptyl, b.  $135^\circ$ ;  $\alpha$ -bromolauryl, b.  $188^\circ$ ; bromophenylpropionyl, b.  $160^\circ$ ;  $\alpha$ -bromophenylacetyl (84% yield), b.  $150^\circ$ , and the chloride, b.  $123^\circ$ . The homologs of trypanamide prepd. show little action on trypanosomiasis animals. It is necessary to use approximately toxic doses to obtain therapeutic action. F. C. H.

Catalytic hydrogenation of cyano derivatives. The reduction of esters of phenylcyanopyrroacetic acid, benzoylcyanacetic acid and benzilideneacyanoacetic acid. H. RUPE AND BERNHARD PIEPER. *Helv. Chim. Acta* **12**, 637-49 (1929).—The reduction with Ni as a catalyst of CN ketones and CN acids gives always the product most suitable for ring formation, if this is at all possible. The reduction of Et phenylcyanopyrroacetate goes as far as the primary amine which splits off EtOH with closing of the 5 ring and gives 4-phenyl-2,3-diketopyrrolidine (I). Yield of crude product 95%. Recrystd. from glacial AcOH it is obtained as white laminas, m.  $295^\circ$ . I gives with  $\text{BzCl}$  and NaOH a Bz deriv., m.  $218^\circ$ , with NaOEt and MeI a mono-Me deriv., m.  $197\text{--}8^\circ$ , with  $\text{PhNHNH}_2$  a phenylhydrazone, m.  $224\text{--}5^\circ$ . The catalytic reduction of  $\text{NCCHBzCO}_2\text{Et}$  gives Et  $\alpha$ -benzoylpropionate, b.  $143\text{--}4^\circ$ . The reduction of Et benzilideneacyanoacetate gives the half aldehyde of benzylmalonic acid (II) and a new amino acid,  $\alpha$ -benzyl- $\beta$ -aminopropionic acid (III). II and III condense together to a Schiff base, which is obtained as a resin and can be sepd. into its components with mineral acid. The constitution of III was proved by the formation with HCNO of 5 benzylhydrouracil. F. J. G. DE LEEUW

The oxide of  $\alpha$ -pinene in the Grignard reaction. II. N. PRILEZHAEV AND V. VERSHUK. *J. Russ. Phys.-Chem. Soc.* **61**, 473-82 (1929).—It was shown earlier that hydration of the oxides of  $\alpha$ - and  $\beta$ -pinenes is always accompanied by decompn. of the unstable glycols, formed as primary products, into unsatd. alcs. of the cyclohexene series. In the case of  $\alpha$ -pinene at least the reaction with Grignard reagents where R is Me, Et or iso-Pr proceeds quite analogously as follows, yielding homologs of 1-menthen-6-ol:

The evolved gases were not analyzed, but the other products strongly indicate the above scheme. Where R is of greater mol. wt.—Bu or Ph—satd. alcs. are obtained. Thus

it appears that the instability of the primary products is a function of the polarity of R as compared to Me, rather than of the spatial relationship of the component parts of the mol. The oxide of 1- $\alpha$ -pinene (I) with MeI and Mg gave 1-menthen-6-ol (II),  $b_{18}$  109–10°,  $d_{15}^{20}$  0.9275,  $\alpha_D^{20}$  +7.90°,  $n_D^{15}$  1.4769. II could not be reduced by the catalytic methods of Skita, Willstätter, or Zelinskii nor with Na metal or amalgam. Reduction by Sabatier's method gave an alc. with intense odor of menthol and wormwood, probably 1-menthanol,  $b_{180}$  223–4°,  $d_4^{20}$  0.9241,  $d_{15}^{15}$  0.9116,  $n_D^{15}$  1.4654. Oxidation of II with  $BzO_2H$  gave 1-menthen-6-ol oxide (III), golden-yellow liquid with camphor odor,  $b_{17}$  147–8°,  $d_4^{15}$  0.9960,  $n_D^{15}$  1.47068, easily sol. in  $H_2O$ , and not further oxidizable by  $KMnO_4$ . Hydration of III gave a triol which on distg. split out 1 mol.  $H_2O$  giving presumably a menthenediol,  $b_{21}$  170–5°. The oxide of  $\delta$ - $\alpha$ -pinene (IV) with EtI and Mg gave 1-ethyl-4-isopropyl-1-cyclohexen-6-ol,  $b_{80}$  142–43.5°,  $d_4^{25}$  0.9315, with an odor recalling geraniol, easily oxidized by  $KMnO_4$ , and adding 2 atoms Br.  $EtCO_2H$  was a product of oxidation I with iso-PrCl and Mg gave presumably 1,4-diisopropyl-1-cyclohexen-6-ol,  $b_{17}$  132–3°,  $d_4^{20}$  0.9246,  $d_{15}^{15}$  0.9176. IV with iso-BuBr and Mg gave a nonhomogeneous product. A small amt. of substance of empirical formula  $C_{10}H_{16}(OH)CH_2CHMe_2$  was obtained,  $b_{17}$  140–3°, having unsatd. properties due ostensibly to the presence of a labile bridge I with PhBr and Mg gave  $C_{10}H_{16}(OH)Ph$ , viscous liquid easily oxidized by  $KMnO_4$ ,  $b_{17}$  189–90°,  $d_4^{15}$  1.0126,  $n_D^{15}$  1.53554.

LEWIS W. BUTZ

**Photobromination of coumarin.** DAVID M. WILLIAMS. *J. Chem. Soc.* 1929, 1383–4.—Berthoud and Nicolet (*C. A.* 22, 1912) showed that the photobromination of  $\alpha$ -phenylcinnamitrile in  $CCl_4$  leads to an equil. The same is true of coumarin (I). The light source was a Hg vapor quartz lamp and the solns. were in quartz tubes 18 in. from the lamp. With concns. of I and Br of  $1/_{60}$  M in  $CCl_4$ , equil. was reached in 25 min. and 85.6% of the Br had reacted; in  $CHCl_3$  equil. was reached in 45 min. and 65.8% of the Br had reacted. With the nitrile under identical conditions, equil. was reached in about 60 min. in  $CCl_4$  at 40.2% addn. and in about 150 min. in  $CHCl_3$  at 35.4% addn. In the thermal reaction the velocity of bromination was invariably greater in  $CHCl_3$ ; it seems that the reverse is true for the photobromination

**Ozonide of nopinene.** GEORGES BRUS AND G. PEYRESBLANQUES. *Bull. inst. pin.* 1929, 157–8.—See *C. A.* 23, 829.

A. PAPINEAU-COUTURE

**Contribution to the study of retene.** LI MAN CHEUNG. *Bull. inst. pin.* 1929, 159–64, 183–90, 215–20; cf. *C. A.* 23, 3467.—A more detailed account of the investigation is given, together with a bibliography of 36 references. A. PAPINEAU-COUTURE

**Chemistry of the caryophyllene series. II. Clovene and isoclovene.** GEO. G. HENDERSON, ROBT. O. O. MCCRONE AND JOHN M. ROBERTSON. *J. Chem. Soc.* 1929, 1368–72; cf. *C. A.* 20, 1072.—Wallach and Walker (*Ann.* 271, 283 (1892)) showed that when carophyllene alc. (I) is heated with  $P_2O_5$ , clovene (II) is produced; other methods of dehydrating I are now shown to give the same result; in no case is carophyllene (III) obtained. Other reactions which are reported indicate that under the influence of mineral acids and other reagents, III readily undergoes ring closure with formation of II or of another tricyclic sesquiterpene which is very similar to II in its phys. properties. II is attacked by  $KMnO_4$  but so far no definite oxidation products have been isolated; all attempts to prep. an alc. from II by hydration have been unsuccessful; II does not appear to yield eudalene or cadalene when heated with S and therefore does not belong to either the eudesmene or the cadinene group of the sesquiterpenes.  $P_2O_5$  (90 g.) added to 70 g. of  $\beta$ -I, m. 96°, at its m. p., gives a mixt. of II and isoclovene (IV),  $b_{10}$  115–8°, isolated as the mono-HCl deriv., m. 87°; the mono-HBr, m. 75°. If the above expt. is carried out at the b. p. of the alc., only II is formed. Pure IV, isolated from the HCl deriv. with AcONa and AcOH,  $b_{12}$  130–1,  $d_4^{19}$  0.943,  $n_D^{19}$  1.5039,  $[\alpha]_D^{14}$  –56.6°,  $[R_L]_D$  64.11. IV is much more unstable than II, resinifying quickly when exposed to air and becoming sticky and resinous even when enclosed. Heating IV with  $P_2O_5$  at its b. p. completely decomps. it. IV united with 1 mol. Br, but the dibromide is also very unstable. The HCl deriv. is stable when pure. The HCl salt of IV and AcOAg in AcOH in the dark for 4 days gives isoclovene acetate, m. 25–6°; hydrolysis with MeOH-KOH gives the alc., m. 98°,  $[\alpha]_D^{25}$  227° (EtOH, c 0.5714). It does not add Br and does not yield esters with  $Ac_2O$ ,  $(C_6H_5CO)_2O$  or  $p$ - $O_2NC_6H_4COCl$ ;  $Ac_2O$  dehydrates the alc. The relation of IV to II remains for the present unsettled.

C. J. WEST

**The reaction between carboxylic acid halides and organomagnesium halides.** HENRY GILMAN, R. E. FOTHERGILL AND H. H. PARKER. *Rec. trav. chim.* 48, 748–51

(1929).—G. and Heckert (*C. A.* 22, 2741) have found that an excellent yield of  $\text{Ph}_3\text{COH}$  can be obtained in the reaction between  $\text{BzCl}$  and  $\text{PhMgBr}$ ; they suggested the possible use of acid chlorides as a satisfactory method for the prepn. of tert. alcs. The present paper deals more fully with these reactions and with some preliminary expts. on the prepn. of ketones from acid chlorides and Grignard reagents. The following compds. were prepd. by the addn. of 0.2 mole of the acid chloride to a well-cooled soln. of 0.5 mole  $\text{PhMgBr}$ :  $\text{Ph}_2\text{CMeOH}$ , yield 39%;  $\text{Ph}_2\text{CEtOH}$ , 57%; 1,1-diphenylbutene, 84%, the tert. alc. having lost water with formation of the olefin;  $\text{PhCEt}_2\text{OH}$  from  $\text{BzCl}$  and  $\text{EtMgBr}$ , 93%;  $\text{PhCPr}_2\text{OH}$  by means of  $\text{PrMgBr}$  and  $\text{BzCl}$ , 81%. On using only 0.17 mole of  $\text{BzCl}$  and 0.5 mole  $\text{PhMgBr}$  96.6% crude  $\text{Ph}_3\text{COH}$  was obtained and 91.5% of the pure product, recrystd. from benzene. An attempt to prep. aldehydes or sec. alcs. from nascent  $\text{HCOCl}$ ,  $\text{CuCl}$  and a Grignard reagent did not give the desired result. When 0.5 mole  $\text{PhMgBr}$  was added slowly (in the course of 2 hrs.) to 0.5 mole  $\text{BzCl}$  in 500 cc. well-cooled ether, 29% of  $\text{Ph}_2\text{CO}$  and 38.0% of  $\text{Ph}_3\text{COH}$  were obtained; on adding only 0.3 mole of the Grignard reagent to the same amount of  $\text{BzCl}$  the yield of  $\text{Ph}_2\text{CO}$  was 45.2%. C. F. VAN DUIN

**Pyrogenic decomposition of the perhydrides of fluorene and acenaphthene under hydrogen pressure.** N. A. ORLOV and M. A. BELOPOLSKI. *Ber.* 62B, 1226–34 (1929); cf. *C. A.* 22, 75.—In the earlier paper it was shown that under the action of a high H pressure and high temps. on some condensed aromatic hydrocarbons the partial hydrogenation, which is the 1st reaction, diminishes the stability of the mols. and causes a rupture of the union between the resulting  $\text{CH}_2$  groups. Because the so-called polynaphthenes are an important constituent of many raw materials which are subjected to heat treatments of various kinds in industry, O. and B. chose for a similar study the readily available acenaphthene and fluorene perhydrides as examples of such polynaphthenes. The pressure hydrogenation product of fluorene (which, in addn. to the true perhydride, always contains a mixt. of its cleavage products) was subjected to berginization at  $380^\circ$  under 70–5 atm. initial H pressure; the light fraction of the product (up to  $150^\circ$ ) contained a mixt. of monocyclic naphthenes and the following fraction gave indications of the presence of bicyclic naphthenes; the formation of such substances is readily explainable by the scheme:

The identification of perhydridene would have confirmed this view but perhydridene, especially when it is mixed with its homologs, is not readily characterized; mild dehydrogenation gives only bicyclononadiene instead of indene and higher temps. decomp. it into  $\text{C}_6\text{H}_6$  and its homologs. After it had been found that when pure perhydridene is dehydrogenated in a tinne-Fe tube at  $750^\circ$  indene can be detected in the products, along with cyclopentadiene,  $\text{C}_{10}\text{H}_8$  and chrysene, the higher fractions of the above berginization product were subjected to the same process, with similar results. The berginization of perhydroacenaphthene is somewhat more difficult and accompanied by the formation of larger amts. of gaseous products; direct cracking gives indene, its homologs, cyclopentadiene,  $\text{C}_6\text{H}_6$  hydrocarbons and unidentified unsatd. compds. C. A. R.

**Compounds of metal chlorides and polyenes.** HANS V. EULER AND HARRY WILLSTAEDT. *Arkiv Kemi, Mineral. Geol.* 10B, No. 9, 1–6 (1929). (In German); cf. *C. A.* 20, 215, 3020; 23, 1941.—Carotin and carotinoids give color reactions with  $\text{SbCl}_3$  and certain other metal chlorides. The colored products, not hitherto isolated, may be mol. compds. of metal chlorides and the  $-\text{CH}:\text{CH}-$  group of polyenes. v. E. and W. have studied the metal chloride compds. of simple members of the diphenylpolyene series. Stilbene and  $\text{SbCl}_3$  in anhyd.  $\text{CHCl}_3$  gave  $(\text{PhCH}:\text{CH})_2 \cdot 2\text{SbCl}_3$ , colorless crystals, sintering at  $100^\circ$  and m.  $106-7^\circ$ . Isostilbene gave the same product. Both stilbene and isostilbene and  $\text{FeCl}_3$  gave  $(\text{PhCH}:\text{CH})_2 \cdot 2\text{FeCl}_3$ , which is almost colorless and may be heated to  $326^\circ$  without melting. Dimethylfulvene and  $\text{SbCl}_3$  or  $\text{FeCl}_3$  gave dark solns. from which only resinous products could be sepd. Diphenylbutadiene and  $\text{FeCl}_3$  gave  $(\text{PhCH}:\text{CH})_2 \cdot 2\text{FeCl}_3$ . Carotin and  $\text{SbCl}_3$  gave the characteristic blue color in max. intensity only with a very large excess of  $\text{SbCl}_3$ . Carotin seemed to combine with a max. of  $8\text{SbCl}_3$ , but upon purification and recrystn. the product became progressively less blue and approached the compn.,  $\text{C}_{40}\text{H}_{56} \cdot 2\text{SbCl}_3$ . M. W. MCP.

The structure of the octalin (octahydronaphthalene) obtained from tertiary decalol (hydroxydecahydronaphthalene). S. S. NAMEKIN AND E. V. GLAGOLEVA. *J. Russ.*

*Phys.-Chem.* 61, 535-40(1929).—Nametkin and Madaeva-Sulcheva earlier (cf. *C. A.* 20, 1802) investigated the following series of reactions: Decalin (decahydronaphthalene)  $\xrightarrow{\text{HNO}_3}$

$\xrightarrow{\text{tert-nitrodecalin}} \xrightarrow{\text{tert-aminodecalin}} \xrightarrow{\text{tert-decalol}} \xrightarrow{-\text{H}_2\text{O}}$  octalin (I). The structure of I (2 are possible) was left undetd. The action of  $\text{BzO}_3\text{H}$  on I is now reported, yielding octalin oxide (II) convertible to a glycol (III) which by dehydration gives hexalin (hexahydronaphthalene) (IV). This indicates the ditertiary structure for III, and hence the structure shown below for I, since secondary-tertiary alicyclic glycols yield ketones by dehydration (cf. *Ann.* 396, 268). The structure of IV was not detd

II was prepd. according to Prilezhaev; yield 8 g.,  $b_p$  82-3°,  $d_4^{20}$  1.003,  $n_D^{20}$  1.4847, from 16.2 g. I. 7.5 g. II gave 5 g. III, consisting of a mixt. of the *cis*- and *trans*-isomers, which were not sep'd. The fact that III was impure is traced to the decalin used, which probably contained both *cis*- and *trans*-isomers. Three g. III by dehydration in a sealed tube at 150° with dil.  $\text{H}_2\text{SO}_4$  gave 3 g. IV,  $b_p$  75-6°,  $d_4^{20}$  0.9726,  $n_D^{20}$  1.5322. IV with concd.  $\text{HNO}_3$  gives a rose color, changing to deep violet on shaking; with a 1:1 mixt. of EtOH and  $\text{H}_2\text{SO}_4$ , IV gives a rose color which gradually becomes red and then reddish violet.

**Hydrogenation of ar-1,3-dibromo-2-tetralol by means of bromine.** MILOSLAV JAKŠ. *Chem. Obzor* 1, 285(1926); *Collection Czechoslov. Chem. Comm.* 1, 215-56 (1929); cf. *C. A.* 16, 4201; 19, 3486.—Since nitronaphthalene is obtained when ar-nitrotetralin is heated with 2 mols. of  $\text{Br}_2$  at 100° and the resulting dibromotetralin is decompd. at 140-80°, it was expected that 1,3-dibromo-2-tetralol (I) would undergo the same type of reactions to yield 1,3-dibromo-2-naphthol. However, a mixture of 3,6-naphthol (II), m. 124-5°, and 3,7-dibromo-2-naphthol (III), m. 185-6°, was actually obtained. The Br in position 1 is lost. The compd. II was also obtained by addn of the product of diazotization of 3,6,2- $\text{C}_{10}\text{H}_6\text{Br}_2\text{NH}_2$  to boiling  $\text{H}_2\text{SO}_4$  (62.5%) and hot satd. aq.  $\text{CuSO}_4$ . The compd. m. 134-5° to which Franzen and Stauble (*C. A.* 16, 1945) assigned structure II is shown by J. to be 4,6-dibromo-2-naphthol (III). When 1,4,6-tribromo-2-naphthol which yields IV upon reduction with tin and HCl is treated with  $\text{HNO}_3$  it yields a dibromonaphthoquinone m. 150°, different from the 3,6 dibromonaphthoquinone m. about 200° (decompn.) prepd. from 1,3,6,2- $\text{C}_{10}\text{H}_4(\text{NO}_2)_2(\text{NH}_2)_2$ . Neither II nor III is reduced by tin and HCl but with Na-Hg (2.5%) they yield 6,2-naphthol and 7-bromo-2-naphthol, m. 132-3°, resp. The latter compd. was also prepd by addn. of boiling 2-hydroxy-7-naphthylhydrazine in dil. HBr to hot  $\text{CuBr}_2$  in the same solvent. Bromination of II gives a quant. yield of 1,3,6-tribromo-2-naphthol (V), reduction of which with tin and HCl yields II. V is also obtained when the acetate of I is heated with more than 2 mols. of  $\text{Br}_2$ . With 2 mols. it yields the same mixt as does I.

**The methylated nitronaphthylamines.** V. VESELÝ AND A. VOJTĚCH. *Collection Czechoslov. Chem. Comm.* 1, 104-18(1929).—Methylation of 3,1- $\text{C}_{10}\text{H}_6(\text{NO}_2)\text{NH}_2$  with  $\text{Me}_2\text{SO}_4$  gave 45% of the *di-Me* deriv., m. 64-5°; its *picrate*, m. 188.9°. Similarly 1,3- $\text{C}_{10}\text{H}_6(\text{NO}_2)\text{NH}_2$  gave 40% of its *di-Me* deriv., m. 65°; its *picrate*, m. 194.6°. Methylation of the 4,1-compd. is more difficult and gave some of the *mono-Me* deriv., m. 184-5°, as well as a small yield of the *di-Me* deriv., m. 65-6°. Nitro-1-dimethylaminonaphthalene,  $b_{14}$  182-4°, was prepd. by treating 1,2- $\text{C}_{10}\text{H}_6(\text{NO}_2)_2$  with  $\text{NHMe}_2$ . Heating with concd. NaOH gave 2-nitro-1-naphthol, m. 127-8°. 5,1- $\text{C}_{10}\text{H}_6(\text{NO}_2)\text{NH}_2$  gave a *di-Me* deriv.,  $b_{14}$  194-6°, with  $\text{Me}_2\text{SO}_4$ . Methylation of the 8,1-compd gave only 8-nitro-1-methylaminonaphthalene, m. 81°. The 5,2-compd. gave a *di-Me* deriv., m. 74°, obtained from its *picrate*, m. 176-7°. Similarly the 8,2-isomer gave a *di-Me* deriv., m. 77°, obtained either from its *picrate*, m. 174-6°, or its *perchlorate*, and the 6,2-compd. gave a *di-Me* deriv., m. 164°, identified by its *picrate*, m. 158-60°. 6-Nitro-2-methylaminonaphthalene, m. 185-6° (*picrate*, m. 138-40°), was obtained by saponif. 6-nitro-2-methylacetamido-2-naphthalene, m. 186-7°. Nitration of 1- $\text{C}_{10}\text{H}_7\text{NMe}_2$  in AcOH gave 2,4,1- $\text{C}_{10}\text{H}_6(\text{NO}_2)_2\text{NMe}_2$ , m. 88°, which with concd. NaOH gave 2,4,1- $\text{C}_{10}\text{H}_6(\text{NO}_2)_2\text{OH}$ . Carrying out the same nitration in  $\text{H}_2\text{SO}_4$  gave a compd. m. 137-8° whose N content corresponded to a dinitro deriv. but the position of the nitro groups

was not established. The mother liquor gave a *picrate*, m. 162–4°, from which a *compd.*, b<sub>14</sub> 192–5°, corresponding to 5,1-C<sub>10</sub>H<sub>6</sub>(NO<sub>2</sub>)NMe<sub>2</sub> was obtained. Nitration of 2-C<sub>10</sub>H<sub>7</sub>NMe<sub>2</sub> in AcOH gave a *dinitro deriv.*, m. 157–8°, but the position of the nitro groups was not detd. A similar nitration but in H<sub>2</sub>SO<sub>4</sub> gave an eutectic, m. 52°, composed of a mixt. of 5,2- and 8,2-C<sub>10</sub>H<sub>6</sub>(NO<sub>2</sub>)NMe<sub>2</sub>. These were identified by nitrating the eutectic and forming the corresponding dinitro derivs. Treating 1,8,2-C<sub>10</sub>H<sub>7</sub>(NO<sub>2</sub>)<sub>2</sub>NMe<sub>2</sub> with NaOH gave 1,8,2-C<sub>10</sub>H<sub>6</sub>(NO<sub>2</sub>)<sub>2</sub>OH, m. (decompn.) 198–9°. Attempts were made to prep. dyes from these nitrodimethylnaphthylamines and their derivs. but with only slight success.

R. C. ROBERTS

*N*-Methyl derivatives of 2-phenylnaphthylene-1,3-diamine. WM. S. KENTISH. *J. Chem. Soc.* 1929, 1169–75.—The isomerism of  $\alpha$ -(I) and  $\beta$ -*N,N'*-dimethyl-2-phenylnaphthylene-1,3-diamines (II) (Lees and Thorpe, *C. A.* 2, 125; Gibson, Kentish and Simonsen, *C. A.* 22, 4501) can be explained by assuming either definite structural differences between I and II or by an interlocking of the Ph and Me groups producing *cis-trans* isomerism. Arguments against the latter assumption are given; among these is the behavior with HNO<sub>2</sub>, which converts I into II, the mechanism of which is now examd. I (7 g.) in 70 cc. 15% HCl and 1.95 g. NaNO<sub>2</sub> in 10 cc. H<sub>2</sub>O give 70% of  $\alpha$ -3-nitrosomethylamino-1-methylamino-2-phenyl-1,2-dihydronaphthalene (III), which first seps. as the unstable form, yellow needles, and quickly passes into orange-red prisms, m. 154°. Reduction of III with Sn and concd. HCl in glacial AcOH gives nearly quant. I. III and excess of NaNO<sub>2</sub> in 20% HCl slowly give the  $\beta$ -dinitrosoamine, m. 179°. III does not react with *p*-MeC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>Cl in C<sub>6</sub>H<sub>6</sub>N after heating 4 hrs. at 100° and is not methylated by Me<sub>2</sub>SO<sub>4</sub> in NaOH-MeOH. The slow reaction of III with HNO<sub>2</sub> indicates that the transformation occurs when the second NO group is introduced. In order to discover whether the transformation was in any way specifically assocd. with the first NO group, the action of HNO<sub>2</sub> upon various derivs. was studied. The Ac deriv. and a slight excess of NaNO<sub>2</sub> in 10% HCl give  $\beta$ -3-acetylmethylamino-1-methylamino-2-phenylnaphthalene, m. 147°, which is not appreciably hydrolyzed by boiling with 40% NaOH or alc. H<sub>2</sub>SO<sub>4</sub>; refluxing with concd. HCl for 4 hrs. gives a good yield of II. The *p*-MeC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub> deriv. and HNO<sub>2</sub> give *nitroso-p-toluenesulfonyl-beta-N,N'-dimethyl-2-phenylnaphthylene-1,3-diamine*, pale yellow, m. 183°. Reduction and hydrolysis give II. The transformation is thus seen to be unassocd. with the nature of the 1st substituent in I and the evidence shows that HNO<sub>2</sub> effects a definite structural transformation. II and 1 mol HNO<sub>2</sub> in 20% HCl give a small amt. of the  $\beta$ -mononitrosoamine (IV), deep-red needles with violet fluorescence, m. 248°, most of the II being recovered unchanged. IV yields a yellow HCl salt, rather sparingly sol. in H<sub>2</sub>O; the EtOH and C<sub>6</sub>H<sub>6</sub> solns. of IV are deep crimson, whereas those of III are only slightly colored. The acetylacetate of 2-phenylnaphthylene-1,3-diamine (Atkinson and Thorpe, *J. Chem. Soc.* 89, 1906(1906)) is not a true salt, as, on treatment with NaOH, it passes immediately into the di-Ac deriv., m. 272°.

C. J. WEST

Transposition and purity of the methyl naphthyl ketones. L. CHOPIN. *Bull. soc. chim.* 45, 167–8(1929).—Two isomerides ( $\alpha$  and  $\beta$ ) of C<sub>10</sub>H<sub>7</sub>COMe have been previously obtained (Durand, *C. A.* 18, 1466).  $\beta$  is unstable and spontaneously isomerizes into  $\alpha$ . The transformation requires germs of  $\alpha$ , and several yrs. to be completed. NaOH does not have any influence on the transformation; heat or HCl favors it very much, H<sub>2</sub>SO<sub>4</sub> less and H<sub>3</sub>PO<sub>4</sub> very little. The solvents used in the synthesis reaction are without effect. The  $\alpha$ -compd. can be prepd. in a very high degree of purity, but the  $\beta$ -form contains always traces of PhNH<sub>2</sub> and PhN:C, which favor its deterioration. A purification with H<sub>3</sub>PO<sub>4</sub> yielded only mediocre results.

ALBERT L. HENNE

The preparation of  $\beta$ -naphthoic acid from  $\beta$ -naphthylmagnesium bromide. HENRY GILMAN AND NINA B. ST. JOHN. *Rec. trav. chim.* 48, 745–7(1929).—Recently Loevenich and Loeser (cf. *C. A.* 21, 1649) found that  $\beta$ -C<sub>10</sub>H<sub>7</sub>Br could only be induced with some difficulty, with the aid of MeI as a catalyst, to enter into reaction with Mg and that the  $\beta$ -C<sub>10</sub>H<sub>7</sub>MgBr, thus prepd. did not give  $\beta$ -naphthoic acid on treatment with CO<sub>2</sub>. According to G., Zoellner and Dickey (cf. *C. A.* 23, 2934), however,  $\beta$ -C<sub>10</sub>H<sub>7</sub>Br reacts easily with Mg, giving the Grignard compd. in 83% yield, while almost invariably the yield of CO<sub>2</sub>H acids from Grignard reagents and CO<sub>2</sub> is distinctly high and approaches the quantity of available Grignard reagent within 15–20%, lower and higher yields being observed occasionally. Accordingly the authors prepd.  $\beta$ -C<sub>10</sub>H<sub>7</sub>MgBr from 0.1 mol  $\beta$ -C<sub>10</sub>H<sub>7</sub>Br, 0.1 atom Mg and 60 cc. of ether with a yield of 80%. This soln. gave on treatment with CO<sub>2</sub> (G. and Parker, *C. A.* 19, 467) 62.7% crude  $\beta$ -naphthoic acid, m. 165°, which was completely pure after one recrystn. from dil. alc. C. F. VAN DUIN

Color and chemical constitution. XXV. Quantized phenomenon—halochromic color of the doubly-linked diphenylene compounds. JAMES MOIR. *Trans. Roy. Soc.*

*S. Africa* 18, Pt. 2, 137-42(1929); cf. *C. A.* 23, 383.—The following compds., practically all the possible ones in which 2 benzene rings are connected, in *o*-positions, by 2 identical or different elements, or their related oxidized groups, were prepd. and examd in  $H_2SO_4$  soln., dihydroanthracene, anthracene, anthranol, anthraquinol, anthraquinone, dihydrophenazine, phenazine, phenazonium, phenozine (diphenylene dioxide) (I), thianthrene (V), thianthrene monoxide, thianthrene dioxide, thianthrene trioxide, thianthrene tetroxide, selenanthrene (VI), selenanthrene oxide, dihydroacridine, acridine, acridone, xanthene, xanthidrol, xanthone, thioxanthene, thioxanthidrol, thioxanthone, selenoxanthone, phenoxazine, phenoxazonium, phenthiazine, phenthiazonium, phenarsenazine, phenarsenazonium, phenthioxine (II), phenthioxine oxide, phenthioxine dioxide, phenoxselenine (III), phenoxselenine oxide, phenoxtellurine (IV), phenoxtellurine oxide, phenoxtellurine quinhidrone, phenoxtellurine dioxide. The colors depend largely on the fact that all the mols. are of the same shape, and all are nearly of the same size. The recorded wave numbers,  $\nu$ , of the strongest lines of most of the substances can, by certain divisions, be made to yield the same quotient. For I the divisor is 6, for II and for III 7, for IV 8, for V 7.5, and for VI 5.5 and 8.5. These give as the quotients for each approximately 2440. This, in turn, is divided by 4, giving 610. If this latter value be permitted to vary from 594, for the lowest element, to 612, for the highest, all the observations may be represented by this "const." multiplied by integral nos. These range rather widely, from 22-51, yet show some regularities. Replacing  $CH_2$  by O reduces the relative integer by 3, while with  $NH$ , for  $CH_2$ , the alteration is  $\pm 1$ . The whole phenomenon seems to depend on the rings rather than the linkages. Variations of the latter change the const., 610, by about 1-2%. While the no. of valency electrons, in the benzene ring 30, and in the mols. of most of the substances utilized 68, is doubtless concerned in these results, no satisfactory accounting of the values has been arrived at. Similarly,  $\nu$  values for some of the members of the  $Ph_3COH$  series, dihydroxybenzhydrol, benzaurin, malachite green, aminomalachite green, diaminobenzhydrol, fuchsin, dimethyldiaminofuchson, give integers ranging from 34 to 84.

G. A. HILL

**Sulfonation of phenanthrene. I. New monosulfonate.** LOUIS F. FIESER *J. Am. Chem. Soc.* 51, 2460-70(1929); cf. Werner, *Ann.* 321, 248(1902).—The *p*-toluidine salts are suitable for the identification of the phenanthrenesulfonic acids; 1, m. 267° (cor.); 2, m. 291°; 3, m. 222°; 9, m. 235°; by these salts a few mg. of the acid or of any of its metal salts may be identified. In working up the sulfonation mixt it is more convenient to prepare first a Na salt mixt. and to treat a soln. of this with only enough  $BaCl_2$  to cause the pptn. of the Ba 2-salt. Sulfonation at 120-5° for 4 hrs. gives 18% of the 2-acid and 27% of the 3-acid, but the most suitable conditions for these acids is sulfonation with 2 mol. equivs. of concd. acid at 120-5°. Sulfonation at 60° gives 18% of the 2-acid, 19% of the 3-acid, 13% of the 9-acid and 4% of the 1-acid, although at least 8% are formed. The original should be consulted for the details of the sepn. of these products. *K phenanthrene-1-sulfonate*, plates, sparingly sol. in EtOH, the Ba and Fe" salts were prepd.; *Me ester*, m. 102°;  $CrO_3$  and the K salt give *K phenanthrenequinone-1-sulfonate*, orange-yellow plates; the concd.  $H_2SO_4$  soln is deep red. Alkali fusion and acetylation give *1-acetoxyphenanthrene*, m. 135-6°; alk hydrolysis gives *1-phenanthrol*, m. 157° (cor.); *Me ether*, m. 105° (picrate, m. 154° (cor.)); *1-acetoxyphenanthrenequinone*, orange, m. 206° (cor.); *1-HO deriv.*, fiery red, m. 227° (cor.). Through the azo dye and 4-amino-1-phenanthrol, there results *1,4-phenanthrenequinone*, yellow, m. 155° (cor.). *Triacetyl-4-amino-1-phenanthrol*, m. 143°; *1,4-Diacetoxyphenanthrene*, m. 137-8°; *1,4-diacetoxy-9,10-phenanthrenequinone*, golden yellow, m. 184° (cor.). **II. Disulfonation.** *Ibid* 2471-86.—In order to gain an idea of the compn. of the mixt. of disulfonates which is produced by the action of  $H_2SO_4$  on phenanthrene, the 2- and 3-mono- $SO_3H$  acids were sulfonated and the products were at least partly identified by sepg. the mixt. of diacetoxyphenanthrenes which were obtained as the results of alkali fusion and acetylation. The second substituent enters the unsubstituted terminal nucleus in the 6-, 7- and 8-positions. No attempt will be made to abstract the details of the sulfonations or the method of identification of the compds. isolated. *Diacetoxyphenanthrenes*: 2,6-, m. 122-3°; 2,7-, m. 183.5° (cor.); 2,8-, m. 125°; 3,6-, m. 124.5°; 3,8-, m. 186° (cor.). *Dihydroxyphenanthrenes*: 2,6-, m. 239° (all cor.); 2,7-, m. 265°; 3,6-, m. 225°; 3,8-, m. 253°; 2,8-, m. 205° *Dimethoxyphenanthrenes*: 2,6-, m. 87°; 2,7-, m. 167-8°; 3,6-, m. 105°; 3,8-, m. 117°. *Diacetoxy-9,10-phenanthrenequinones* (all m. ps. cor.): 2,6-, golden yellow, m. 220-1°; 2,7-, orange, m. 244°; 2,8-, orange, m. 223-4°; 3,6-, yellow, m. 232°; 3,8-, orange-yellow, m. 221-2°. *Dihydroxy-9,10-phenanthrenequinones*: 2,6-, reddish brown; 3,6-, orange-red; color reactions are given for the 5 isomers with  $H_2SO_4$ , 0.1 N and 6 N

**Reactions of sugars and their decomposition products with nitrogenous substances.**  
**I. Formation of imidazoles.** K. BERNHAUER. *Z. physiol. Chem.* **183**, 67-73 (1929).—The prepn. of methylimidazole by treatment of a sugar with  $\text{NH}_4\text{OH}$  contg.  $\text{Zn}(\text{OH})_2$  depends upon the intermediate formation of  $\text{AcCHO}$  and  $\text{CH}_3\text{O}$ . At room temp. the reaction requires 6 months for completion, but at  $40^\circ$  it is complete in 24 hrs. and at  $100^\circ$  in 2 hrs. The best yields are obtained with 20-5%  $\text{NH}_4\text{OH}$  satd. with  $\text{Zn}(\text{OH})_2$ .  $\text{AcCHO}$  gives a better yield than glucose, but here the addn. of  $\text{CH}_3\text{O}$  is necessary. Apparently the  $\text{CH}_3\text{O}$  required results from breakdown of sugar but not from that of  $\text{AcCHO}$ . Addn. of  $\text{AcH}$  gives rise to the formation of methylimidazole and dimethylimidazole in the proportions of 3:2 or 2:1. The intermediate formation of  $\text{AcCHO}$  from glucose was demonstrated by isolation and identification of the phenyllosazone, the *p*-nitrophenyllosazone and the disemicarbazone.

**Mechanism of the azide rearrangement.** GARFIELD POWELL. *J. Am. Chem. Soc.* **51**, 2436-9 (1929).—In testing the univalent N hypothesis of azide rearrangement, the decompn. of  $\text{BzN}_3$  in the presence of  $\text{Ph}_3\text{C}$  was studied; no reaction with  $\text{Ph}_3\text{C}$  took place and  $\text{BzN}_3$  decompd. in the presence of  $\text{Ph}_3\text{C}$  as easily and smoothly as when alone. *Dibenzylacetazide*, m.  $51-3^\circ$ ; on standing for 1 day, it decomp.; the same decompn. takes place on warming or melting, giving *dibenzylmethyl isocyanate*, thick liquid, which, on warming with  $\text{EtOH}$  for 1 hr., gives *dibenzylmethylethylurethane*, m.  $106.7^\circ$ , while  $\text{PhNH}_2$  in  $\text{C}_6\text{H}_6$  gives *dibenzylmethylphenylurea*, m.  $153-4^\circ$ . **2-Phenyl-4-quinolylformohydroxamic acid** (*atophanhydroxamic acid*), m.  $155-6^\circ$ , is formed from the Me ester and  $\text{NH}_2\text{OH}\cdot\text{HCl}$  with  $\text{MeONa}$ ; Cu salt, emerald-green; Bz deriv., m.  $150.1^\circ$ .

**Action of diazo compounds on tetrazolyl disulfides.** R. SROLLÉ, FRITZ HENKE-STARK AND HERTHA PERREY. *Ber.* **62B**, 1112-8 (1929); cf. Schönberg, Schütz and Peter, *C. A.* **23**, 3216.—The authors have some time since (Henke-Stark, *Diss. Heidelberg*, 1928; Perrey, *Ibid.*) studied the action of  $\text{CH}_2\text{N}_2$ ,  $\text{MeCHN}_2$  and  $\text{N}_2\text{CHCO}_2\text{Et}$  on 1-substituted bis-[5-tetrazolyl] disulfides (I). Two classes of compds. were obtained, sometimes together. To one is assigned the structure (II) of methylene addn. products; they give with  $\text{AgNO}_3$  ppts. which are apparently not homogeneous, for analysis gives no values corresponding to  $\text{AgNO}_3$  addn. products;  $\text{CH}_2\text{N}_2$  cannot be made to react with other disulfides, and the results of cleavage, reduction and oxidation thus far obtained agree best with the structure II. The second type of compds. obtained are mercaptals (III), also prepd. for comparison by the action of the dihalogen derivs. on the Na salts of the corresponding 5-mercaptotetrazoles. They give no ppts. with alc.  $\text{AgNO}_3$ . *Methylenebis-[1-phenyl-4,5-dihydro-5-tetrazolyl] disulfide* (II, R = H, R' = Ph) (61 g. from 64 g. I (R = Ph) and  $\text{CH}_2\text{N}_2$  in cold  $\text{Et}_2\text{O}$ ), yellowish, m.  $124^\circ$ , begins to decomp. about  $160^\circ$ , mol. wt. in  $\text{C}_6\text{H}_6$  332, the  $\text{Et}_2\text{O}$  filtrate yields, when evapd. and treated with  $\text{MeOH}$ , 1 g. of *dimercaptomethane bis-[1-phenyl-5-tetrazolyl] ether* (III, R = H, R' = Ph), also obtained from Na 1-phenylmercapto-5-tetrazole and  $\text{CH}_2\text{I}_2$  or  $\text{CH}_2\text{Cl}_2$  in boiling alc., m.  $136^\circ$ , decomp. about  $175^\circ$ .  *$\alpha,\beta$ -dimercaptoethane homolog* (6.5 g. from 10 g. of the Na tetrazole and  $(\text{CH}_3\text{Br})_2$  refluxed 3 hrs.), m.  $150^\circ$ , deflagrates on rapid heating. *Methylenebis-[1-p-tolyl-4,5-dihydro-5-tetrazolyl sulfide]* (30.7 g. from 32.2 g. I (R = *p*- $\text{MeC}_6\text{H}_4$ ), m.  $108^\circ$ , begins

to evolve gas at  $160^\circ$ . *o-Tolyl isomer* (yield, 85%), m.  $118^\circ$ , begins to decomp.  $160^\circ$ . *Dimercaptomethane bis-[1-p-tolyl-5-tetrazolyl] ether*, from the tetrazole and  $\text{CH}_2\text{Cl}_2$ , m.  $136^\circ$ , begins to decomp.  $145^\circ$ ; *o-isomer*, decomp.  $161^\circ$ . *Methylenebis-[1-m-xylyl-4,5-dihydro-5-tetrazolyl sulfide]* (1.8 g. from 2 g. of the I), m.  $106^\circ$ . *Dimercaptomethane bis-[1-methyl-5-tetrazolyl] ether* (20%, together with a very small amt. of a substance m.  $133^\circ$ , from the I and  $\text{CH}_2\text{N}_2$ , and quant. from the tetrazole with  $\text{CH}_2\text{I}_2$ ), m.  $157^\circ$ ; on  $\text{CuO}$  it imparts a distinct light green color to a flame. *Ethylidenbis-[1-phenyl-4,5-dihydro-5-tetrazolyl disulfide]* (7.4 g. from 7.1 g. of the I with  $\text{MeCHN}_2$ ), decomp.  $177^\circ$ .  *$\alpha,\alpha'$ -Dimercaptoethane bis-[1-phenyl-5-tetrazolyl] ether*, obtained in poor yield from the tetrazole and  $\text{MeCHBr}_2$ , m.  $93^\circ$ . *Carbethoxymethienylbis-[1-phenyl-4,5-dihydro-5-tetrazolyl sulfide]* (50% from the I with  $\text{N}_2\text{CHCO}_2\text{Et}$ ), m.  $104^\circ$ , begins to decomp. about  $150^\circ$ , dissolves in  $\text{NaOH}$  (probably with decompn.) but not in  $\text{Na}_2\text{CO}_3$ . *Et dimercaptoacetate bis-[1-phenyl-5-tetrazolyl] ether* (about 50% from the tetrazole and  $\text{Cl}_3\text{CHCO}_2\text{Et}$  in  $\text{C}_6\text{H}_6$  at  $150^\circ$ ), m.  $110^\circ$ , gives with alc.  $\text{AgNO}_3$  a gradually increasing ppt.; when pptd. in finely divided form from alc. by  $\text{H}_2\text{O}$  it dissolves in hot  $\text{NaOH}$

with decompn. for on acidification it evolves  $\text{H}_2\text{S}$ . *Carbomethoxymethylenbis*-[1-phenyl-4,5-dihydro-5-tetrazolyl sulfide] (50%), decomp.  $139^\circ$ . I (R = Ph) shaken with Hg gives Hg 1-phenyl-5-mercaptotetrazole, decomp.  $223^\circ$ .  $\text{CS}(\text{NPh})_2$  with excess of alc.  $\text{AgNO}_3$  forms an addn. compd.,  $\text{C}_{21}\text{H}_{20}\text{N}_2\text{S}$ .  $\text{AgNO}_3$ , decomp. about  $240^\circ$ . C. A. R.

**5-Aminotetrazole.** R. STOLLÉ (WITH E. SCHICK, F. HENKE-STARK AND L. KRAUSS). *Ber.* 62B, 1118–26(1929).—5-Aminotetrazole (I), leaves or prisms with  $\text{H}_2\text{O}$ , m.  $119^\circ$ , is obtained almost quantitatively from aq.  $\text{HN}_3$  and  $\text{NH}:\text{C}(\text{NH}_2)\text{NHCN}$ ; it gives no ppt. with basic or normal Pb acetate in  $\text{H}_2\text{O}$ ; nitrate, decomp.  $174^\circ$ ; *HBr* salt, begins to shrink  $110^\circ$ , m.  $118^\circ$ , evolves gas about  $150^\circ$ . The urea could not be obtained but with  $\text{PhNCO}$  at  $100^\circ$  it readily yields *N*-phenyl-*N'*-5-tetrazolylurea (18 g. from 8.5 g. I), m.  $245^\circ$  (decompn.); the suspension obtained by pptn. from alc. with  $\text{H}_2\text{O}$  is distinctly acid to litmus and dissolves in  $\text{Na}_2\text{CO}_3$  and alkalis; in alc. it gives with  $\text{AgNO}_3$  a white ppt. which is only difficultly sol. in both alc.  $\text{NH}_3$  and concd.  $\text{HNO}_3$ . 5-Tetrazolylurethan (15 g. from 8.5 g. I refluxed in  $\text{CICO}_2\text{Et}$ ), m.  $256^\circ$  (decompn.), forms a strongly acid  $\text{H}_2\text{O}$  soln., gives a Ag salt sol. in  $\text{NH}_3$  and  $\text{HNO}_3$ . With excess of  $\text{AcCl}$  on the  $\text{H}_2\text{O}$  bath, I gives the mono-Ac deriv., m.  $269^\circ$  (decompn.), but when refluxed 8 hrs. with  $\text{Ac}_2\text{O}$  it splits off a mol. of  $\text{N}_2$  and yields 2-methyl-5-acetyl-amino-1,3,4-furodiazole, m.  $180^\circ$  (8.5 g. from 8.5 g. I), identical with the product obtained by acetylating 2-methyl-5-amino-1,3,4-furodiazole. I (10.3 g.) converted into the diazonium sulfate and slowly added to a suspension of  $\text{Cu}(\text{OH})_2$  in  $\text{H}_2\text{O}$  at  $60^\circ$  gives 6.5 g. of 5-hydroxytetrazole, m.  $254^\circ$  (decompn.), whereas with  $\text{H}_3\text{PO}_4$  and  $\text{CuSO}_4$  is obtained tetrazole. The diazonium chloride from 10.3 g. I with  $\text{CuCl}_2$  gives 11.9 g. of the light blue *Cu* salt, detonates on rapid heating, of 5-chlorotetrazole, m.  $73^\circ$ , begins to decomp. about  $120^\circ$ , not attacked by  $\text{SO}_2$ ,  $\text{Na}_2\text{SO}_3$  or  $\text{NaOEt}$  even on long heating. In the same way is obtained the green *Cu* salt (15 g. from 10.3 g. I) of the 5-Br deriv., m.  $156^\circ$  (decompn.). 5-I compd. (70% from diazotized I and KI), decomp. about  $190^\circ$ , reduced by  $\text{SO}_2$  and  $\text{Na}_2\text{SO}_3$  and by  $\text{NaOEt}$  to tetrazole and converted by long boiling with 60%  $\text{NaOH}$  into the 5-HO compd. Diazotized I coupled with  $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$  gives 75% of *N*¹-5-tetrazolyl-*N*²-4'-nitrophenyltriazene, yellowish, deflagrates about  $169^\circ$  on the Maquenne block, forms with alc.  $\text{AgNO}_3$  an orange-yellow ppt. (probably a mono-Ag salt) turned reddish by alc.  $\text{NH}_3$ , cautious addn. of  $\text{Na}_2\text{CO}_3$  or alkali to the fine suspension obtained by pptn. from alc. with  $\text{H}_2\text{O}$  gives first a yellow soln. which changes quite sharply to red as soon as the acid imino H atom has been neutralized; the triazene is also obtained, together with more or less di-[4-nitrophenyl]-triazene, from  $p\text{-O}_2\text{NC}_6\text{H}_4\text{N}_2\text{Cl}$  and I. The diazo-amino compd.  $\text{C}_7\text{H}_7\text{N}_7$  from tetrazole-diazonium chloride and  $\text{PhNH}_2$  deflagrates  $97^\circ$ . 5-Guanylaminotetrazole nitrate (90% from  $\text{NH}:\text{C}(\text{NH}_2)\text{NHCN}$  in hot  $\text{H}_2\text{O}$  with  $\text{HN}_3$  and  $\text{HNO}_3$ ), deflagrates weakly about  $183^\circ$ , gives on repeated crystn. from  $\text{H}_2\text{O}$  the free base, does not m.  $300^\circ$ , which is also obtained from  $\text{NCNH}_2$  and I in  $\text{H}_2\text{O}$  on the  $\text{H}_2\text{O}$  bath and with  $\text{H}_2\text{O}$  at  $200^\circ$  decomp. into I,  $\text{NH}_3$  and  $\text{CO}_2$ , together with a certain amt. of N. C. A. R.

Action of alcoholic hydrochloric acid on methyldiphenyltetrahydropyrone. HUGH RYAN AND J. J. LENNON. *Sci. Proc. Roy. Dublin Soc.* [N. S.] 19, 121–4(1928).—The object was to prove that the 1st stage in the reaction of BzH on methyldiphenyltetrahydro- $\gamma$ -pyrone in the presence of alc. HCl was conversion into methyldiphenylcyclopentenone. A large vol. of the concd. acid gave a product which could be isolated as slightly yellow crystals, m.  $73\text{--}8^\circ$ . PAUL BOONE

New condensations of ketones with phenols. III. Condensation products of mesityl oxide and monohydroxybenzenes. JOSEPH B. NIEDERL (WITH NATHAN AMBINDER, RICHARD CASTY, DE WITT C. KNOWLES, IRVING RAPAPORT AND WM. SASCHER). *J. Am. Chem. Soc.* 51, 2426–30(1929); cf. C. A. 23, 2431.—Addn. of 1 mol. concd.  $\text{H}_2\text{SO}_4$  (in small amts.) to a mol. mixt. of  $\text{AcCH}:\text{CMe}_2$  and  $\text{PhOH}$  at  $0^\circ$  and the mixt. allowed to stand 1 week at  $15\text{--}20^\circ$  gives 2,2,4-trimethylchroman-2-ol (I), m.  $89^\circ$ ; di- $\text{NO}_2$  deriv., m.  $155^\circ$ .  $m\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$  gives the 7- $\text{NO}_2$  deriv. of I, m.  $148^\circ$  and  $p\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$  gives the 6- $\text{NO}_2$  deriv., m.  $132^\circ$ .  $o\text{-MeC}_6\text{H}_4\text{OH}$  gives the 2,4,4,8-tetramethylchroman-2-ol, m.  $120^\circ$ , and  $m\text{-MeC}_6\text{H}_4\text{OH}$  (article says trinitro-*m*-cresol) gives the 2,4,4,7-tetramethyl deriv., m.  $120^\circ$  and also by dehydration di-[2,4,4,7-tetramethylchromanyl] 2-ether, m.  $58^\circ$  (tetra- $\text{NO}_2$  deriv., m.  $145^\circ$ ).  $p\text{-MeC}_6\text{H}_4\text{OH}$  gives only di-[2,4,4,6-chromanyl] 2-ether, m.  $57^\circ$  (tetra- $\text{NO}_2$  deriv., m.  $167^\circ$ ). 3,6-MeCIC $_4$ - $\text{H}_3\text{OH}$  gives di-[5-chloro-2,4,4,7-tetramethylchromanyl] 2-ether, m.  $71^\circ$ . 2,4-Me $_2$ C $_6$ H $_3$ OH gives di-[2,4,4,6,8-pentamethylchromanyl] 2-ether, semi-solid (tetra- $\text{NO}_2$  deriv., m.  $155^\circ$ ). Carvacrol gives di-[2,4,4,8-tetramethylisopropylchromanyl] 2-ether, semi-solid (di- $\text{NO}_2$  deriv., m.  $185^\circ$ ). Thymol gives di-[2,4,4,5-tetramethyl-8-isopropylchromanyl] 2-ether, m.  $136^\circ$  (di- $\text{NO}_2$  deriv., m.  $201^\circ$ ). Reduction of these compds. with HI or Zn and

HCl gives chromans, while on distn. they lose 1 mol.  $\text{H}_2\text{O}$  and form the corresponding chromenes. These products are valuable intermediates for the prepn. of Ph-substituted aldehydes and acids (by oxidation) and by the distn. of the acids or their Na salts so obtainable, the corresponding iso-Pr and iso-Bu phenols can be synthesized; hence this condensation process furnishes an additional means for the introduction of alkyl groups into the  $\text{C}_6\text{H}_5$  ring.

**Benzanthrone.** J. MARTINET AND A. DROBATSCHIEFF. *Chimie & industrie* 21, 227-42, 1149-60 (1929).—A review, with bibliography of 95 references. A. P. C.

**Rotenone.** I. Reduction products of rotenone. F. B. LAForge AND I. E. SMITH. *J. Am. Chem. Soc.* 51, 2574-81 (1929); cf. Kariyone, *C. A.* 17, 3025; 19, 1708, 2485; Butenandt, *C. A.* 22, 3630.—Rotenone (I), the active insecticidal principle of *Derris elliptica*, m.  $163^\circ$ ; a fairly good sample of *Derris* root contains 2.5% I. Catalytic reduction of I with Pt oxide gives, after the absorption of 1 equiv. of H, about equal amts. of dihydrorotenone (II),  $\text{C}_{23}\text{H}_{24}\text{O}_6$ , m.  $164^\circ$  (K. gives  $216^\circ$ ),  $[\alpha]_D^{20} -225^\circ$  (0.3153 g. in 15 cc.  $\text{C}_6\text{H}_6$ ), and an acid (III),  $\text{C}_{23}\text{H}_{24}\text{O}_6$ , m.  $209^\circ$ ,  $[\alpha]_D^{20} 36.2^\circ$  (0.3154 g. in 15 cc.  $\text{CHCl}_3$ ); Pd-BaSO<sub>4</sub> gives the same results, though II predominates in the reduction product. Further reduction of II or III gives the same product, an acid,  $\text{C}_{23}\text{H}_{24}\text{O}_6$ , m.  $215^\circ$ . Reduction of I oxime or II and  $\text{NH}_2\text{OH} \cdot \text{HCl}$  give the oxime of II, m.  $256^\circ$  (decompn.); with concd. HCl this gives quant. an isoxime, m.  $270^\circ$  (decompn.). The benzenesulfonyl deriv. of II m.  $143^\circ$ . The quantities of rotenol (IV) and derritol (V) obtained from I may be varied by varying the % of KOH used: 5%, 2.0 g. IV, 0.1 g. V; 10%, 1.1 and 0.65 g.; 15%, 0.9, 0.95 g.; 20%, 0.2, 1.15; IV m.  $164^\circ$ ; V m.  $120^\circ$ ,  $[\alpha]_D^{20} -66.2^\circ$  (0.1700 g. in 5 cc.  $\text{CHCl}_3$ ); a by-product, m.  $161^\circ$ , with 17.65% MeO is obtained in small yields. Contrary to B., II is converted into dihydrorotenol and dihydrorotenol with Zn in alk. EtOH. Isorotenone yields isoderritol and isorotenol by the same treatment, m.  $133^\circ$  and  $150^\circ$ , resp. The formation of V is independent of an unsatd. bond in I.

C. J. WEST

**A synthesis of 5,7,2',4'-tetrahydroxyflavone and of 7,2',4',6'-tetrahydroxyflavone.** NICHOLAS MICHAEL CULLINANE, JOSEPH ALGAR AND HUGH RYAN. *Sci. Proc. Roy. Dublin Soc.* [N. S.], 19, 77-83 (1928).—The tri-Me ether of phloracetophenone treated with an equal wt. of  $\text{AlCl}_3$ , at  $110^\circ$  yields phloracetophenone 4,6-di-Me ether (I) which upon condensation with 2,4-(MeO)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>Me (II) in the presence of Na gives 2-dihydroxy-4,6,2',4'-tetramethoxybenzoylacetophenone (III), m.  $151^\circ$ . On treatment with HI, the diketone (III) was converted into 5,7,2',4'-tetramethoxyflavone; this with further HI gave 5,7,2',4'-tetrahydroxyflavone, yellow plates almost insol. in water,  $\text{CHCl}_3$  or petroleum. The similar condensation of phloracetophenone tri-Me ether with II produced 2,4,6,2',4'-pentamethoxybenzoylacetophenone (V), m.  $153^\circ$ , readily sol. in hot alc. Treated with HI (d. 1.94) it yielded 7,2',4',6'-tetrahydroxyflavone (VI), m.  $240^\circ$ , minute yellow plates, slightly sol. in  $\text{CHCl}_3$ ; in concd.  $\text{H}_2\text{SO}_4$  the soln. is yellow with greenish blue fluorescence.

PAUL BOONE

**1-Methoxy derivatives of thioxanthone.** KENNETH C. ROBERTS AND SAMUEL SMILES. King's College, London. *J. Chem. Soc.* 1929, 1322-6.—That the basic character of the thioxanthone nucleus as indicated by the stability of its salts is promoted by the presence of the MeO group has been shown in *C. A.* 23, 3706; this influence depends on the position rather than the no. of the MeO groups. The influence of the 1-MeO group is most pronounced. Further evidence of this is now given *p*-MeOC<sub>6</sub>H<sub>4</sub>OH and 2-HSC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, condensed with concd.  $\text{H}_2\text{SO}_4$  at  $15^\circ$  for 15 min. give a mixt. of 1-hydroxy-4-methoxythioxanthone (I) and 4-hydroxy-1-methoxythioxanthone (II), sep'd. by the insolv. of I in 2 N aq. NaOH. I, orange-red, m.  $182^\circ$ ; it does not form a HCl salt or a perchlorate; EtONa in  $\text{C}_6\text{H}_6$  gives a purple Na deriv.; Ac deriv., m.  $138^\circ$ ; diacetoborate, deep red, m.  $205^\circ$ , decompd. by boiling  $\text{H}_2\text{O}$ ;  $\text{H}_2\text{O}_2$  gives the dioxide, orange, m.  $184^\circ$ ; Na salt, red. II, yellow, m.  $270^\circ$  (decompn.); di-HCl salt, crimson; perchlorate; Ac deriv., yellow, m.  $133^\circ$ ; II is decompd. by  $\text{H}_2\text{O}_2$ . 2,3-Dimethoxythioxanthone yields a chlorostannate, yellow; that of the 1,4-di-MeO deriv. is crimson. Absorption curves are given for the HCl derivs. and diacetoborates of various methylated derivs.

C. J. WEST

**Reaction of piperidine and piperazine with oxides of ethylene, isobutylene and trimethylethylene.** K. A. KRASUSKII AND K. G. KOSENKO. *Ukrainskii Khim. Zhur.* 4, Sci. Pt., 37-59 (1929).—The reaction of piperidine and piperazine with  $\alpha$ -oxides proceeds with the formation of  $\alpha$ -amino alcs. and those with oxides of isobutylene and trimethylethylene result in the formation of amino alcs., developing considerable heat. Theoretical and exptl. data are given concerning these reactions. ROBERT SCHLESS

**The action of piperazine upon the oxide of isosafrole.** T. S. KUSNER. *Ukrainskii*

*Khem. Zhur.* 4, Sci. Pt. 85-8(1929); cf. *C. A.* 23, 2162.—The piperazine (I) deriv. of isosafrole oxide (II),  $\text{CH}_2\text{O}_2\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{CH}(\text{CH}_3)\text{N}(\text{CH}_2)_4\text{NH}$ , was prepd. when 5.3 g. of I in 10 g. of alc. and 11 g. of II in 10 g. of alc. were allowed to stand at room temp. for 28 hrs., the ppts. being removed every 2 days for 10 days, then after 4, 6 and 8 days; yield, 10.7 g. of a white powder, insol. in org. solvents, m.  $238-40^\circ$  (decompn.). The HCl salt was formed on boiling the base in  $\text{H}_2\text{O}$  and adding HCl until dissolved.

CHAS. BLANC

**10-Chloro-5,10-dihydrophenarsazine and its derivatives. IX. Synthesis of nitromethylphenylamine-6'-arsonic acids and their conversion into nitromethyl derivatives of 10-chloro-5,10-dihydrophenarsazine.** Constitution of 10-chloro-5,10-dihydrophenarsazine. CHARLES S. GIBSON AND JOHN D. A. JOHNSON. *J. Chem. Soc.*, 1929, 1229-62; cf. *C. A.* 23, 3709.—This is a study of the cyclization of diphenylamine-6'-arsonic acids in greater detail than has previously been reported, since, if the ring-formation process follows the course which has been suggested, all substituted acids having a  $\text{NO}_2$  or other strongly electronegative group in the *o*-position to the :NH group should yield isolable dichloroarsines on reduction in the presence of HCl; further evidence regarding the constitution of the reduction product of 3-nitrodiphenylamine-6'-arsonic acid is also presented. 2-Bromo-3-nitrotoluene,  $b_p$   $135-6^\circ$ ,  $b_m$   $157^\circ$ , m  $41-2^\circ$ , results in 67% yield from the 2- $\text{NH}_2$  deriv. through the diazo reaction. Notes are given on the prepn. of the other 7 known isomers. 4,2-Me( $\text{H}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ , *o*-Br $\text{C}_6\text{H}_4\text{NO}_2$ ,  $\text{K}_2\text{CO}_3$ , AmOH and a trace of Cu powder, boiled 5 hrs., give 66% of 2-nitro-3'-methylphenylamine-6'-arsonic acid (I), golden yellow, m.  $215-7^\circ$  (decompn.); the alkali salts give deep red solns.; the Mg salts form on boiling with magnesia mixt. Reduction of I in a mixt. of EtOH and HCl contg. a trace of I with  $\text{SO}_2$  gives 2-nitro-3'-methylphenylamine-6'-dichloroarsine, bright yellow, m.  $129.5-30^\circ$ ; if the crude product is boiled in AcOH for 1.5 hrs., HCl is evolved and there results 72% of 10-chloro-4-nitro-7-methyl-5,10-dihydrophenarsazine, deep red, m.  $201-2^\circ$ , oxidized by  $\text{H}_2\text{O}_2$  in AcOH in 15 min. at  $100^\circ$  to 4-nitro-7-methylphenarsazinic acid, yellow, m.  $300-3^\circ$  (decompn.); the Na salt is orange; 4- $\text{NH}_2$  deriv., needles which do not m. at  $310^\circ$ , by reduction with  $\text{Fe}(\text{OH})_2$ , which is further reduced by  $\text{SO}_2$  in EtOH-HCl to 10-chloro-4-amino-7-methyl-5,10-dihydrophenarsazine-HCl, grayish yellow, m.  $216-20^\circ$  (decompn.). 3-Nitro-3'-methylphenylamine-6'-arsonic acid, prepd. like I from *m*-Br $\text{C}_6\text{H}_4\text{NO}_2$ , yellow, m.  $191-2^\circ$  (73% yield); reduction with  $\text{SO}_2$  in EtOH-HCl gives 10-chloro-1(or 3)-nitro-7-methyl-5,10-dihydrophenarsazine, deep red, m.  $253-5^\circ$  (decompn.); in EtOH-HBr the 10-Br deriv., deep red, m.  $248-50^\circ$  (decompn.). *p*-Br $\text{C}_6\text{H}_4\text{NO}_2$  gives 89% of 4-nitro-3'-methylphenylamine-6'-arsonic acid, yellow, m.  $276^\circ$  (decompn.). 5,2-Me( $\text{H}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$  and *o*-Br $\text{C}_6\text{H}_4\text{NO}_2$  give 65% of 2-nitro-4-methylphenylamine-6'-arsonic acid, deep bronze-yellow, m.  $226-7^\circ$ , decompn.  $234^\circ$ ; the alkali salts give deep red solns. Reduction with  $\text{SO}_2$  in HCl gives an oily dichloroarsine which, boiled with AcOH for 2 hrs., gives 10-chloro-4-nitro-8-methyl-5,10-dihydrophenarsazine, red, m.  $206^\circ$ ; oxidation with  $\text{H}_2\text{O}_2$  gives 4-nitro-8-methylphenarsazinic acid, orange-yellow, decompn.  $297-300^\circ$ ; the salts are characteristic: Na, bronze-yellow needles;  $\text{NH}_4$ , deep red needles whose aq. soln. evolves  $\text{NH}_3$ ; Ba, reddish yellow needles; Ca, orange-yellow needles; Mg, orange plates; salts of the heavy metals are amorphous. 2,6-Br( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{Me}$  and *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{AsO}_3\text{H}_2$  give 68% of 3-nitro-2-methylphenylamine-6'-arsonic acid, pale yellow, m.  $223-4^\circ$  (decompn.); Na salt, pale yellow needles;  $\text{NH}_4$  salt, yellow; Ba and Ca salts, pale yellow. Reduction with  $\text{SO}_2$  in HCl gives 10-chloro-3-nitro-4-methyl-5,10-dihydrophenarsazine, yellow, m.  $216.5^\circ$ ; 10-Br deriv., orange-yellow, m.  $216.5^\circ$ . Oxidation of the Cl deriv. with  $\text{H}_2\text{O}_2$  gives 3-nitro-4-methylphenarsazinic acid, pale yellow, does not m.  $306^\circ$ . 2,5-Br( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{Me}$  gives 73% of 4-nitro-2-methylphenylamine-6'-arsonic acid, pale yellow, m.  $277^\circ$  (decompn.); salts: Na, golden yellow needles;  $\text{NH}_4$ , orange-yellow needles, giving a deep red aq. soln.; Ba, yellow plates; Ca, orange-yellow plates; Mg, orange, amorphous; Hg salts, yellow needles; Ag and Pb, yellow.  $\text{SO}_2$  in HCl gives 10-chloro-2-nitro-4-methyl-5,10-dihydrophenarsazine, deep yellow, m.  $303-5^\circ$  (decompn.); 10-Br deriv., orange-yellow, m.  $301-2^\circ$  (decompn.); either deriv., oxidized with  $\text{H}_2\text{O}_2$ , gives 2-nitro-4-methylphenarsazinic acid, pale yellow, does not m.  $306^\circ$ ; salts:  $\text{NH}_4$ , yellow needles, whose aq. soln., on boiling, evolves  $\text{NH}_3$ ; Ba, pale yellow needles; Ca, orange-yellow prisms; Ag, yellow, amorphous; Mg, yellow prisms; Hg, pale yellow, amorphous; Pb, deep yellow, amorphous; K, golden yellow prisms, giving an orange-red concd. or pale yellow dil. aq. soln., changed to deep purple on addn of 25% KOH; Na, orange-yellow needles. 2,5-Br( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{Me}$  gives 56% of 5-nitro-2-methylphenylamine-6'-arsonic acid, light yellow, m.  $224-6^\circ$  (decompn.); the alkali salts form deep red aq. solns.; Ba salt, yellow plates; Ca salt, bright yellow

needles;  $\text{Hg}^{++}$  salt, yellow needles;  $\text{Mg}$  salt, colorless. Reduction with  $\text{SO}_2$  in  $\text{HCl}$  gives 5-nitro-2-methyldiphenylamine-6'-dichloroarsine, bright yellow, m.  $173^\circ$ , which gives in boiling  $\text{AcOH}$  10-chloro-1-nitro-4-methyl-5,10-dihydrophenarsazine, deep red, m.  $258-60^\circ$ ; the corresponding dibromoarsine and 10-Br deriv. yellow, m.  $164^\circ$  and deep red, decomp.  $272^\circ$ . Oxidation of the Cl deriv. with  $\text{H}_2\text{O}_2$  gives 1-nitro-4-methylphenarsazinic acid, orange-yellow, darkens  $295^\circ$  but does not m.  $305^\circ$ . 2,3-Br( $\text{O}_2\text{N}$ )- $\text{C}_6\text{H}_4\text{Me}$  gives 35% of 2-nitro-6-methyldiphenylamine-6'-arsonic acid, golden yellow, m.  $195-7^\circ$ ; the salts are yellow to orange-yellow; reduction gives 2-nitro-6-methyldiphenylamine-6'-dichloroarsine, orange-yellow, m.  $104-5^\circ$ ; the dibromoarsine, bronze-orange, m.  $97-8^\circ$ . 4,3-Br( $\text{O}_2\text{N}$ )- $\text{C}_6\text{H}_4\text{Me}$  gives 2-nitro-4-methyldiphenylamine-6'-arsonic acid, golden yellow, m.  $227-9^\circ$  (decompn.); the 6'-dichloroarsine, orange-yellow, m.  $91-3^\circ$ ; 10-chloro-4-nitro-2-methyl-5,10-dihydrophenarsazine, deep red, m.  $187-8^\circ$ ; 10-Br deriv., deep crimson, m.  $186-8^\circ$ ; 4-nitro-2-methylphenarsazinic acid, yellow, decomp.  $305^\circ$ ; the Ba salt, deep yellow needles, and the Ca salt, plates, are characteristic. 3,5-Br( $\text{O}_2\text{N}$ )- $\text{C}_6\text{H}_4\text{Me}$  gives 88% of 5-nitro-3-methyldiphenylamine-6'-arsonic acid, pale yellow, m.  $228-30^\circ$  (decompn.); salts: Ca, yellow needles; Ba, yellow plates; Na, deep reddish brown; Mg, yellow needles. Reduction with  $\text{SO}_2$  gives 10-chloro-1(or 3)-nitro-3(or 1)-methyl-5,10-dihydrophenarsazine, orange, decomp.  $245-7^\circ$ ; 10-Br deriv., red, m.  $237-42^\circ$ . 1(or 3)-Nitro-3(or 1)-methylphenarsazinic acid, yellow, does not m.  $300^\circ$ . 4,2-Br( $\text{O}_2\text{N}$ )- $\text{C}_6\text{H}_4\text{Me}$  gives 3-nitro-4-methyldiphenylamine-6'-arsonic acid, bright yellow, m.  $165-6^\circ$ , isolated through the Ba salt, golden yellow plates with  $\text{H}_2\text{O}$ . Reduction with  $\text{SO}_2$  gives a mixt. of 10-chloro-2-methyl-3-nitro- and 10-chloro-1-nitro-2-methyl-5,10-dihydrophenarsazine, orange-yellow, m.  $257-8^\circ$  (decompn.) and bright red, m.  $225-6^\circ$  (decompn.); the oxidation products, 1- and 3-nitro-2-methylphenarsazinic acids, yellow, do not m.  $297^\circ$ , could not be distinguished from each other. 3,6-Br( $\text{O}_2\text{N}$ )- $\text{C}_6\text{H}_4\text{Me}$  gives 86% of 4-nitro-3-methyldiphenylamine-6'-arsonic acid, pale yellow, decomp.  $200^\circ$ ; reduction gives 10-chloro-2-nitro-1(or 3)-methyl-5,10-dihydrophenarsazine, orange-yellow, m.  $236-8^\circ$  (decompn.), oxidized to 2-nitro-1(or 3)-methylphenarsazinic acid, yellow, does not m.  $308^\circ$ ; Na salt, crimson needles. The following general conclusions may be drawn from the above and earlier work: All substituted nitrodiphenylamine-6'-arsonic acids (II) in which the  $\text{NO}_2$  group is in the  $\alpha$  position to the  $:\text{NH}$  group, on reduction in the presence of  $\text{HCl}$ , yield dichloroarsines, all II in which the  $\text{NO}_2$  group is in the  $p$ -position to the  $\text{NH}$  group on reduction yield the corresponding cyclic Cl compd.; this is also true of all II in which the  $\text{NO}_2$  group is in the  $m$ -position to the  $\text{NH}$  group, with the exception of the 5-nitro-2-methyl deriv. All substituted 10-chloro-4-nitro-5,10-dihydrophenarsazines are crimson, have lower m. ps. than other nitro-10-chloro derivs. and are volatile under diminished pressure at the ordinary temp. All substituted 10-chloro-2-nitro derivs. are yellow, are sol with difficulty in the usual solvents and generally have very high m. ps. There is a greater tendency for ring closure in the case of Br compds. than in the case of the Cl compds.

**Meriquinoid derivatives of the phenarsazine series.** II. G. A. RAZUVAEV, *Ber* 62B, 1208-20(1929); cf. C. A. 23, 3708.—It was shown in the earlier paper that As substituted derivs. of dihydrophenarsazine add, with varying ease, 1 atom of  $\text{H}$  to form intensely colored solns. of meriquinoid derivs. From a careful study of the action of  $\text{O}$  on these colored solns. it follows that 2 reactions take place: a very rapid splitting off of the added  $\text{H}$  and a slow further oxidation to the phenarsazinic acid,  $\text{C}_6\text{H}_4\text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_2\text{H}$ ; the absorption of  $\text{O}$  is at first very rapid and then suddenly

slows down, the soln. becoming colorless. About 0.5 atom of  $\text{O}$  is absorbed, the further oxidation requires many days. To det. the influence of nucleus substituents on the addn. of  $\text{H}$ , the 2(or 4)-Me (I), 2,7(or 4,5)-di-Me (II), 1,2-benzo (III), 3,4,5,6-dibenzo and 3,6-dinitro derivs. of 10-chloro-9,10-dihydrophenarsazine (IV), and also 10-chlorophenoxarsine were studied. Only I, II and III added 1 atom  $\text{H}$  on heating with  $\text{HCO}_2\text{H}$ , as detd. from the amt. color of the reduced solns.

spends to 1 atom;  $\text{HCl}$  is split off and the halogen replaces the  $\text{H}$  in the  $\text{NH}$  group. With I and II the reduced solns. are intensely red, with III dark violet. phenarsazinic acid formed by oxidizing the reduced soln. of IV m. about  $325^\circ$  (decompn.); with III it is so unstable that it could not be isolated. 10-Br deriv. of III, from the reduced soln. with Br, m.  $209^\circ$ ; 10-I compd., orange-red, m.  $202-3^\circ$ , sol. in concd.  $\text{H}_2\text{SO}_4$  with red color. I, from  $m\text{-MeC}_6\text{H}_4\text{NHPh}$  and  $\text{AsCl}_3$  in  $o\text{-C}_6\text{H}_4\text{Cl}_2$ , yellow, m.  $195-6^\circ$ ; 10-Br deriv., yellow, m. about  $220^\circ$  (decompn.); I compd., orange-red, m.  $188^\circ$ . II, from  $(m\text{-MeC}_6\text{H}_4)_2\text{NH}$  and  $\text{AsCl}_3$ , yellow, m.  $250-2^\circ$ ; 10-I deriv., m.  $241-4^\circ$ . C. A. R.

**Alkaloids of Sinomenium and Cocculus. XXV. Alkaloids of *Stephania tetrandra***  
S. Moore. 2. H. KONDO AND K. YANO. *J. Pharm. Soc. Japan* 49, 315-32 (1929); Abstract sect. 49, 51-4; cf. *C. A.* 22, 2359.—In paper 1 was reported the isolation of 3 kinds of alkaloids from *Stephania tetrandra*, one of which was called *tetrandrine* (I), and it was suspected that I might contain the benzyltetrahydroisoquinoline nucleus further proof for the presence of II in I. *Des-N-tetrandrine*, m. 221°, which was obtained by Hofmann's decompn. of I, shows the presence of 1 double bond by Wijs' method. This fact is difficult to explain since compds. contg. II usually give a compd. having 2 double bonds. By repeating H.'s decompn. of I, an  $\alpha$ -methine (III) (Et<sub>2</sub>O-sol., m. 172°, [ $\alpha$ ]<sub>D</sub><sup>14</sup> 11.09°) and a  $\beta$ -methine (IV) (Et<sub>2</sub>O-insol., m. 227° (decompn.), [ $\alpha$ ]<sub>D</sub><sup>18</sup> 14.64°) were obtained at the 1st stage of the decompn. These compds. contained only 1 double bond. In the 2nd stage of the decompn., the same *des-N-tetrandrine* (V), m. 221°, [ $\alpha$ ]<sub>D</sub><sup>16</sup> 11.69, was obtained from III or IV. It also contained only 1 double bond. Since oxidation of V gave a di-CO<sub>2</sub>H acid with the same no. of C atoms bound instead of 2 in V, it is assumed that in H.'s decompn. of I, the dehydration takes place in the direction of  $\alpha, \alpha'$ -positions to the N atom instead of the  $\alpha$  N-positions due to the stability of H<sub>2</sub> in the PhCH<sub>2</sub>-group as indicated by the following scheme:

In the 1st stage of the oxidation of V with KMnO<sub>4</sub>, *des-N-tetrandrinedicarboxylic acid* (VI) (MeO)<sub>2</sub>C<sub>14</sub>H<sub>10</sub>O(CO<sub>2</sub>H)<sub>2</sub>, m. 130°, was obtained. Further oxidation gave *des-N-tetrandrinedicarbonylic acid*, (MeO)<sub>2</sub>C<sub>13</sub>H<sub>8</sub>CO(CO<sub>2</sub>H)<sub>2</sub>, m. 145° (*semicarbazone*, m. 305°. Direct oxidation of I with an excess of KMnO<sub>4</sub> also gave VII. VII and HBr gave an acid (VIII), m. 282-5°. Methylation of VIII with Me<sub>2</sub>SO<sub>4</sub> gave VII. KOH fusion of VII gave 3,4-(HO)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>H and HOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H. This fact shows that VII has the structure of 2-methoxydiphenyl ether-4,4'-dicarbonylic acid. From the reactions given above the structure IX is proposed for I.

Properties of nicotine and its derivatives. I. Molecular extinction coefficients.

NAO UYER

THOMAS M. LOWRY AND WM. VIVIAN LLOYD. *J. Chem. Soc.* 1929, 1376-82.—Nicotine and its derivs. show a strong absorption band at 2850 A. U., which is twice as strong in the  $\text{ZnCl}_2$  compd. and in the methiodides but is 10 times weaker when the base is dissolved in  $\text{H}_2\text{O}$ . It is therefore suggested that the aq. soln. may contain an unionized hydrate or pseudo-base of the type investigated by Decker in the isoquinoline series (*C. A.* 6, 225). Curves are given for nicotine in  $\text{H}_2\text{O}$  and cyclohexane, for the  $\text{ZnCl}_2$  compd. in  $\text{H}_2\text{O}$  and for the isomethiodide, isomethiodide HI and dimethiodide in  $\text{H}_2\text{O}$ .  
C. J. WEST

**Nicotine tetrachloriodide.** FREDERICK D. CHATTAWAY AND GEORGE D. PARKES. *J. Chem. Soc.* 1929, 1314-7.—Nicotine (I) (10 g.) in 20 cc. cooled concd. HCl and a soln. of  $\text{ICl}_3$  (prepd. by satg. a suspension of 8 g. I in 100 cc. concd. HCl with Cl) give quant. nicotine tetrachloriodide (II),  $\text{C}_{10}\text{H}_{14}\text{N}_2 \cdot 2\text{HICl}_4$ , orange, m.  $150^\circ$ , which is very stable; it does not lose weight when exposed for a considerable period in a vacuum desiccator over  $\text{CaO}$ ; it is decompd. by aq. alkalis and more slowly by  $\text{H}_2\text{O}$  alone, giving mainly a mixt. of I and nicotinic acid (III), together with iodate and iodide. III (10 g.) in 150 cc. concd. HCl and 20 g. I, satd. with Cl, give nearly quant. the tetrachloriodide, yellow, m.  $137^\circ$ . Methyl *N*-methylnicotinate tetrachloriodide, bright yellow, m.  $110^\circ$ . Trigonelline tetrachloriodide, bright yellow, m.  $122^\circ$ . Decompn. of II by  $\text{Na}_2\text{SO}_3$  gives 90% of I. Two recrystns. of crude II from glacial AcOH freed it from the tetrachloriodides of the other bases present in technical I. From 200 g. dried dark rag tobacco, ground with 80 g. NaOH in 1 l.  $\text{H}_2\text{O}$  and steam-distd. until 1800 cc. distillate had been collected, there were obtained 22 g. pure II and from this, 4.5 g. pure I.  
C. J. WEST

**Kauri-resins.** J. R. HOSKING. *Rec. trav. chim.* 48, 622-36(1929).—This research was undertaken with the view to investigate the compn. of kauri-resins of different ages, viz., (a) Kauri-resin, freshly prepd. from the tree; (b) the same resin after exposure to the air during 1.5 or 4.5 years ("Buschharz"); (c) fossil kauri-resin ("range gum"); (d) kauri-resin, obtained from the peat-moors ("Sumpsharz"), the method of investigation being as follows. The resin was first distd. with water and sepd. in this way into essential oil, water-sol. gum and resin, which were further investigated more fully. The gum was obtained in a dry condition by concentrating the aqueous distillate to a small vol. and adding alc., the process being repeated once more with the filtrate. Only in the case of the freshly prepd. resin was a sufficient amt. of the gum obtained for further investigation; it was, however, possible to show that in all cases the gum contains a small amt. of Mn. On hydrolysis of the gum (case a) with 5%  $\text{H}_2\text{SO}_4$  and destruction of the galactose in the soln. obtained, an osazone could be prepared m.  $158^\circ$  and a *p*-bromophenylhydrazone m.  $162^\circ$ , showing that the pentose present in the gum is *l*-arabinose. The filtrate from the prepn. of the gum yields an osazone m.  $186-90^\circ$ , indicating the presence of *d*-glucose. The resin was sepd. into neutral components, low-melting resinic acids ( $\alpha$ -resin) and high-melting resinic acids ( $\beta$ -resin) in the following way (cf. Baker and Smith, *Pines of Australia* 343(1910)). The pulverized resin was extd. with ether, in which the neutral components and the  $\alpha$ -resin are sol. while the  $\beta$ -resin is not. The neutral components were then sepd. from the  $\alpha$ -resin by means of the K salts, while small amts. of the  $\alpha$ -resin present in the  $\beta$ -resin and small amts. of the  $\beta$ -resin present in the  $\alpha$ -resin were obtained by conversion of the resinic acids into the K salts in alc., the K salts of the  $\alpha$ -resin being sol. in EtOH and those of the  $\beta$ -resin insol. in this solvent. The essential oil from the fresh resin consists almost entirely of *d*- $\alpha$ -pinene,  $d_4^{25}$  0.8535,  $n_D^{20}$  1.4658,  $[\alpha]_{D_{401}}^{20}$  22.20°, which was obtained after several fractionations in 92% yield. In case b only the components of a 4.5-year old specimen were investigated in detail; the essential oil again almost entirely (89%) consisted of *d*- $\alpha$ -pinene,  $d_4^{25}$  0.8529,  $n_D^{25}$  1.4633,  $[\alpha]_{D_{401}}^{25}$  10.08°. Fractional distn. of the essential oil from "range gum" (case c) gave 63% *d*- $\alpha$ -pinene,  $d_4^{15}$  0.8662,  $n_D^{15}$  1.4604,  $[\alpha]_{D_{401}}^{15}$  10.90°, and 6% of a high-boiling fraction of camphor-like odor, which probably contains fenchyl alc. The essential oil obtained in case d gave 30.5% *d*- $\alpha$ -pinene,  $b_{788}$  155-6°,  $d_4^{15}$  0.8632,  $n_D^{25}$  1.4653,  $[\alpha]_{D_{401}}^{15}$  11.24°; 38.5% dipentene, contg. some *d*-limonene,  $b_{788}$  175-7°,  $d_4^{14}$  0.8460,  $n_D^{14}$  1.4752,  $[\alpha]_{D_{401}}^{14}$  2.36°; 12.9% *d*-fenchyl alc. (from which 7.5% were isolated) and a resinous residue, amounting to 12.4%. It thus appears that the % of pinene decreases regularly with increasing age of the resin, the optical rotation of the pinene decreasing in the same sense. Probably the dipentene and the fenchyl alc. are formed from the pinene under the influence of water and salts. The investigation of the resins left behind after the distn. of the crude resins with water, gave the following results for acid no.,  $\alpha$ -resin,  $\beta$ -resin and non-

volatile neutral components, resp.: (a), 103, 63%, 19%, 10%; (b), 77, 39%, 45%, 9%; (c), 65, 35%, 48%, 9%; (d), 64, —, —, —; from which it appears that the amt. of  $\alpha$ -resin decreases and that of  $\beta$ -resin increases with increasing age of the crude resin; probably the latter is formed from the  $\alpha$ -resin. The amts. of water-sol. gum were 1.1, 0.3, 0.2 and 0.2% in (a), (b), (c) and (d); the m. p. of the  $\alpha$ - and  $\beta$ -resins: (a) 121–4° and 233–6°, (b) 120–4° and 235–7°, (c) 120–5° and 232–7°; the yield of essential oil: (a) 9.6%, (b) 5.0%, (c) 4.0%, (d) 1.0%; and the amt. of the  $\alpha$ - and  $\beta$ -resins: (a) 89.1%, (b) 94.7%, (c) 95.8%, (d) 98.8%.

C. F. VAN DUIN

**Lichen substances. V. Constitution of thamnolic acid. I.** YASUHIKO ASAHINA AND SETZUJI IHARA. *Ber.* 62B, 1196–207 (1929); cf. C. A. 23, 2982.—According to Hesse, thamnolic acid (I), from *Thamnolia vermicularis*, has the compn.  $C_{20}H_{18}O_{11}$  and on heating with  $Ba(OH)_2$  decomps. into thamnolinic acid,  $C_{16}H_{20}O_9$  (II), MeOH and 3  $CO_2$ . Recently A. and I. obtained from *Cladonia flabelliformis* Flk. v. *polyductyla* (Flk.) Wainio 0.34% *l*-usnicic acid and 1.2% I; the properties of the I agreed well with those given in the literature but the C and H contents (54.46, 3.99%) were somewhat lower than those found by H. I was therefore prepd. from *T. vermicularis* also and found to be identical with the other product. H.'s higher C content was probably due to the fact that the I is unstable, and, on unnecessarily long drying at a high temp., loses  $CO_2$  and becomes contaminated with substances richer in C. Because of its low soly., b.-p. detns. of the mol. wt. are also not reliable and even in Rast's micromethod  $CO_2$  is evolved during the heating with camphor. Although I is turned yellow by alkalis and therefore the end point is not sharp it can be approximately titrated with 0.1 N alkali and hematoxylin; there were thus obtained the values 423 and 442 (calcd. on the basis of a tribasic-acid) for its mol. wt.; the MeO content (7%) gives a mol. wt. of 440 on the assumption that I contains one MeO group. On the basis of these results A. and I. assign to I the formula  $C_{19}H_{16}O_{11}$ , which they have confirmed by degradation expts. The presence of a C:O group in I was shown by the formation of hydrazones. Heated with  $KHCO_3$ ,  $Ba(OH)_2$  or KOH it gave orcinol mono-Me ether (III) and everninic acid (IV), but none of H.'s II could be detected. The m. p. of IV varies greatly according to the method of crystn. and values ranging from 145° to 170° are given in the literature. The highest m. p. (172°) was obtained after recrystn. from petroleum ether, but the same prepn. recrystd. from  $H_2O$  or alc. melted lower (153°, 168°, etc.), and it is quite likely that H.'s acid, m. 163°, was really IV. With  $PhNH_2$  at 200°, I gives the anilide of IV; with hot MeOH only the Me ester of IV was obtained. When it is heated in an open vessel with AcOH, I remains for the most part unchanged but in a sealed tube at 150° it undergoes deep-seated decompn. and gives III, methyl-*p*-orsellinic acid (V) and a yellow substance, thamnol,  $C_8H_8O_4$  (VI), which is of pronounced acid character and at the same time an aldehyde, for it dissolves in  $NaHCO_3$  and in  $NaHSO_3$  and forms an anil and hydrazones. Only about 0.2 g. VI was obtained in this way from 2 g. I, but when 5 g. I was heated in an open dish with pelargonic acid to 200°,  $CO_2$  was evolved (beginning at 170°) and by extg. the resulting dark oil with hot  $NaHSO_3$ , acidifying and shaking out with  $Et_2O$ , about 2 g. VI was obtained; steam distn. of the pelargonic acid mixt. left III behind. VI contains 1 atom of O more than atranol (*p*-orsellinic aldehyde) (VII), which it greatly resembles in appearance and chem. properties. Reduction of VI by the Clemmensen method gave a phenol  $C_8H_{10}O_3$  (VIII) which is exceedingly sensitive to alkalis. If VI is a hydroxyatranol, VIII should be *hydroxy- $\beta$ -orscinol*, 1,4,2,3,5- $C_8H_8Me_2(OH)_3$ ; this compd. was synthesized (see following abstr.) and proved to be identical with VIII. VI must therefore be 4-methyl-2,3,5-trihydroxybenzaldehyde (the other possible structure, with the Me and CHO groups reversed, seems less probable). When I in  $KHCO_3$  was heated with  $Na_2SO_3$ , the dark color of the soln. being discharged by addn. of  $NaHSO_3$  from time to time, there sepd., on acidifying and cooling, a di- $CO_2H$  acid  $C_{10}H_{10}O_6$  (IX), which lost  $CO_2$  at 205° and yielded III. IX must be the mother substance of IV and V which it forms according as it splits off  $CO_2$  from the one or the other  $CO_2H$  group. I can therefore be assigned the structure

, the position of the depside

union being chosen arbitrarily. I, best recrystd. from  $Me_2CO$ , m. 212–4° (decompn.), gives a brownish red color with alc.  $FeCl_3$ , sol. in alkali carbonates and hydroxides with deep yellow color, in hot KOH plus  $CHCl_3$  with red color and greenish fluorescence; aniline salt, from the components in hot alc., orange-yellow, m. 206–8°, sol. in alkalis with red color turning yellow on heating, in  $Et_2O$  with yellow color discharged by shaking with dil. HCl; phenylhydrazone, yellow, m. 173–4°; *p*-nitrophenylhydrazone,

orange-yellow, m. 238–9°. Neither hydrazone is attacked by cold dil. HCl. *Anilide* of IV, m. 175°. *Me ester*, m. 67–8°, gives a violet color with traces of alc. FeCl<sub>3</sub>. V, m. 171–2°, gives a red-violet color with traces of alc. FeCl<sub>3</sub>, loses and forms III on heating, identical with the product obtained with Me<sub>2</sub>SO<sub>4</sub> and CH<sub>3</sub>N<sub>3</sub> from *p*-orsellinic acid (m. 171–2°, loses CO<sub>2</sub> at 176°), which was prepd. in 71% yield from orcinol and KHCO<sub>3</sub> at 130°. VI, m. 185°, sol. in alkalis with intensely yellow color, gives with alc. FeCl<sub>3</sub> a green color which gradually darkens; H<sub>2</sub>O turns it olive-green, NaHCO<sub>3</sub> dark wine-red; heating with alkali and CHCl<sub>3</sub> gives a red but not fluorescent soln., H<sub>2</sub>SO<sub>4</sub> a red-brown soln. changed to yellow by H<sub>2</sub>O; with phloroglucinol and hot dil. H<sub>2</sub>SO<sub>4</sub> is formed an orange-red soln. or brown ppt. *Anil*, brownish, m. 128–9°, gives with alc. FeCl<sub>3</sub> a green, then yellow-green color, is insol. in Na<sub>2</sub>CO<sub>3</sub>; *phenylhydrazone*, brown-red, m. 194° (decompn.), gives a brown-red color with alc. FeCl<sub>3</sub>; *p*-nitrophenylhydrazone, brown-violet, m. about 320° (decompn.), sol. in hot Na<sub>2</sub>CO<sub>3</sub> with blood-red color, *triacetate*, from VI and Ac<sub>2</sub>O on the H<sub>2</sub>O bath, m. 133°, is not colored by alc. FeCl<sub>3</sub>, mol. wt. (Rast) 289, forms an *anil*, m. 129°. VIII, m. 157° mol. wt. (Rast) 148, dissolves in H<sub>2</sub>O with light purple color turned to dark violet by heat or by traces of alkali, in alc. with light red color changed to yellow by FeCl<sub>3</sub>, instantly reduces NH<sub>4</sub>-AgNO<sub>3</sub>, is turned green and then dark violet by rubbing with solid KOH; *triacetate*, m. 108° *Methylorcinoldicarboxylic acid* (IX), light brownish, m. 205–6° (decompn.), sol. in alkalis and carbonates without color, gives a brown- to wine-red color with alc. FeCl<sub>3</sub>.

C. A. R  
**Hydroxy-β-orcinol** (1,4-dimethyl-2,3,5-trihydroxybenzene). YASUHIKO ASAHINA AND EI-ITI ISHIBASHI. *Ber.* 62B, 1207–8(1929); cf. preceding abstr.—*p*-Xyloquinone, Ac<sub>2</sub>O and concd. H<sub>2</sub>SO<sub>4</sub> heated on the H<sub>2</sub>O bath until the yellow color of the quinone disappears and poured into H<sub>2</sub>O give the *triacetate*, m. 108°, of *hydroxy-β-orcinol*, m. 158°, obtained from the triacetate with boiling HCl; with Bz<sub>2</sub>O in C<sub>6</sub>H<sub>5</sub>N the orcinol forms a *tribenzoate*, m. 156°.

C. A. R  
**The action of acetic anhydride on carboxylic acids.** A. W. VAN DER HAAR. *Rec trav. chim.* 48, 607–11(1929).—According to some authors the interaction of Ac<sub>2</sub>O and CO<sub>2</sub>H acids leads to the formation of mixed anhydrides, whereas others hold the opinion that only simple anhydrides are formed (cf. van der Haar, C. A. 22, 424, 1342, 1979). From his expts. with the reaction products of several sapogenins, BzOH and *p*-Me<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H v. d. H. (*l. c.*) has drawn the conclusion that mixed anhydrides are not formed in this reaction but addn. products of the anhydride of the acid investigated with 1 mole of Ac<sub>2</sub>O of crystn. This view was based on the fact that on titration of the reaction products in abs. EtOH with alc. KOH, 2 moles of KOH were consumed for the conversion of the Ac<sub>2</sub>O into 2 AcOK and 2 moles for the sapon. of the acetylated OH groups of the sapogenin anhydride, the "ester no." being twice as great as the "acid no." Caudri (*Diss. Leiden* 1928) has found, however, that Ac<sub>2</sub>O on titration with alc. KOH does not give 2 moles of AcOK, but 1 mole of AcOK and 1 mole of AcOEt and thus the explanation of v. d. H. of the fact that the "ester no." is twice as great as the "acid no." cannot be correct. This fact is just as well in agreement with the following course of the reaction: (AcOC<sub>30</sub>H<sub>48</sub>CO<sub>2</sub>)<sub>2</sub>O + Ac<sub>2</sub>O + 2KOH → AcOK + AcOEt + AcOC<sub>30</sub>H<sub>48</sub>CO<sub>2</sub>K + AcCOC<sub>30</sub>H<sub>48</sub>CO<sub>2</sub>Et (I) when it is taken into consideration that esters of sapogenins are sapond. only with difficulty. If the reaction product be a mixed anhydride, the titration with alc. KOH might proceed according to the following equations:

and again the same relation between "acid no." and "ester no." would hold, and a decision between the simple and mixed anhydride formulas cannot be given from the titration values. If, however, after the detn. of the acid no., the AcOEt formed in this reaction is distd. off and estimated quantitatively by sapon., it is possible to draw a conclusion, the alkali necessary for the sapon. of the AcOEt being half the amt. necessary for the neutralization in the case I, equal to that amt. in the case IIa, whereas it should be somewhat smaller if the reaction IIb occurs to some extent. Actually it was found with ursolacetic anhydride, that the amt. of alkali necessary for the sapon. of the AcOEt is somewhat smaller than the amt. consumed in the detn. of the acid no. From these considerations it follows that the interaction of CO<sub>2</sub>H acids with Ac<sub>2</sub>O gives rise to the formation of *mixed anhydrides*. These conclusions only hold for the non-aldehydic and non-ketonic CO<sub>2</sub>H acids; for the aldehydic and ketonic CO<sub>2</sub>H acids, the views published previously (v. d. H., *l. c.*) still hold.

C. F. VAN DUIN

**Lignin. I. Chemical and physical investigation of phenol-lignins.** E. WÄGERKIND AND J. R. KATZ. *Ber.* 62B, 1172-7(1929).—Unlike most lignin preps. the simple phenol-lignins on acetylation yield with surprising ease derivs. having the same compn. when prepd. under different conditions. These Ac derivs. differ strikingly from the original phenol-lignins in their much greater soly. Mol. wt. detns. in AcOH gave remarkably low values (250-70 for 0.5% solns.) and in PhOH and  $C_{10}H_8$  was obtained a min. value of 1800, but in  $CHBr_3$  no depression of the f. p. was observed and ultra-filtration expts. showed that not only in  $CHBr_3$  but also in  $CHCl_3$  and even in AcOH and  $Me_2CO$  the acetylphenol-lignin (I) is present largely in colloidal condition. No attempt is made to explain the apparent discrepancy between these observations and the mol. wts. obtained in AcOH, but it is evident that osmotic measurements will not lead far in this field and it therefore seemed more important to subject I to a more chemical investigation. The smallest possible formula which can be derived for I from its compn. is  $C_{19}H_{20}O_6$ ; it contains one MeO and two Ac groups. Presumably in the formation of phenol-lignin (II), 1 mol. PhOH condenses with the complex  $C_9H_{10}O_3$ , its HO group remaining free. A complex with such a low mol. wt. (166) for the simplest lignin skeleton cannot be reconciled with any of the constitutional formulas which have been proposed, but if the formula for I is doubled ( $C_{38}H_{40}O_{12}$ ) its compn. and that of acetylresorcinol-lignin (III) would correspond with the calcd. values as well as can be expected of amorphous compds. From the various empirical formulas which have been deduced in recent years for the mother substance of lignin, the at. relation C:H:O is 110:100:39, whence it is evident that lignin is not of purely aliphatic character; provisionally Jonas' formula (a combination of 2 cyclohexane, 3 hydrogenated furan and 2 cyclohexene rings) seems useful; the reaction with PhOH could then be explained as consisting in addn. of the PhOH at the double bonds and the calcd. compns. would agree with those found by analysis. As all lignins, including the phenol-lignins, have a colloidal character, the problem of the polymerization which must be assumed falls in the field of highly polymerized substances which is now being so widely investigated. It was of interest, therefore, to apply to the lignins the modern methods of Röntgen spectrography and study of monomol. layers. II generally shows only a ring with the appearance of an amorphous ring, except that it is somewhat broader and more indistinct, somewhat like the principal ring of amorphous C. I and III have rings whose identity period is about 4 Å. U., a no. agreeing approximately with the thickness of a  $C_{10}H_8$  or conjugated system of  $C_6H_6$  rings. Willstätter's lignin showed 2 rings: the inner, much smaller ring is difficult to measure because of its indistinctness. No indications of crystallinity could be detected in any case. The remarkable soly. of I, III and methylphenol-lignin (IV) made it possible to apply to them Katz and Samwel's method (C. A. 22, 3986) of spreading high-mol. substances in monomol. layers on  $H_2O$ . On the basis of the formulas  $C_{38}H_{40}O_{12}$ ,  $C_{42}H_{46}O_{16}$  and  $C_{36}H_{40}O_9$  for the 3 compds., the surface per mol. and the thickness of a monomol. layer, resp., are: I, 83.7, 11.4; III 100.8, 10.2; IV 82.5, 10.1 Å. U. Assuming that the mols. in a homogeneous monomol. layer are as closely packed as possible it follows that these phenol-lignin derivs. have large slab like mols. Either they lie flat on the surface of the  $H_2O$ , in which case they would be remarkably thick for a condensed ring system, or they overlap, like the shingles on a roof. It is very probable that there exists a macromol., in Staudinger's sense, having the form of a large slab; this, in connection with the chem. nature of lignin, would point to a remarkable difference between the 2 chief components of wood; while the cellulose mol. most probably has a linear extension, lignin would have rather a superficial extension.

C. A. R.

**Chemistry of lignin. III. Destructive distillation of lignin from corn cobs.** MAX PHILLIPS. *J. Am. Chem. Soc.* 51, 2420-6(1929); cf. C. A. 22, 3143.—Lignin prepd. from corn cobs by the alkali method (I), the fuming HCl method of Willstätter (II) and by the 72%  $H_2SO_4$  method (III) was subjected to destructive distn. under ordinary atm. pressure and at a temp. of 380-400°. From I there were obtained (av. of 4 expts., calcd. on the basis of ash-free, dry I): 15.5% aq. distillate, 17.7%  $H_2O$ -insol. oily distillate, 52.2% C residue (calcd. on the amt. of lignin used); 13.5% gas (by difference) 0.13%  $Me_2CO$ , 1.9% MeOH, 0.05%  $H_2O$ -sol. acids (calcd. as AcOH). The oily distillate analyzed as follows (the results are expressed as % by wt. of the oil): acids 8.6%; phenols (fraction sol. in 5% KOH and insol. in 5%  $NaHCO_3$ ) 84%; hydrocarbons and neutral compds. 7.2%. In the phenolic portion of the oil guaiacol and eugenol were identified. In the case of II and III the % of aq. distillate was about the same as that obtained from I, whereas the oily distillate was only about 0.5. The % of C residue from II and III were considerably greater than that obtained from I. The % of  $Me_2CO$  and AcOH were considerably greater in the case of II and III than in I, whereas the

% of MeOH was less. This higher % of MeOH is probably due, in part, to the greater MeOH content of I than that of II and III. A possible explanation for the lower yield of AcOH obtained from I is presented.

**Plant pigments. XIII. Bixin.** P. KARRER, A. HELFENSTEIN, ROSE WIDMER AND Th. B. VAN ITALLIE. *Helv. Chim. Acta* 12, 741-56(1929); cf. *C. A.* 23, 2975.-Analytical data indicate that the formula  $C_{24}H_{27}O_3(OCH_3)$  must for the present be accepted for bixin (I). Sapon. of I with MeOH-KOH at 20° and 65°, followed by treatment

a. of I with boiling EtOH gives small amts. of II and varying quantities of *isonorbixin* (III), which is to be differentiated from its isomer by the formation of difficultly sol. alkali salts. III is stable in air and does not melt even at 300°. II can be converted into III by boiling with aq. KOH. Treatment of I in HOAc with  $I_2$  gives *isobixin* (IV), m. 216-7° (decompn.). *Methylbixin* (V),  $C_{24}H_{29}O_2(OMe)_2$ , m. 163-4°, prepd. from I in  $CHCl_3$  with  $CH_3N_3$  in  $Et_2O$ , may under the same conditions be converted into *isobixin Me ester* (VI), m. 200-1°. I and its derivs. are less stable than the corresponding compds. of the isobixin series. Reduction of one mole of II in warm  $NH_4OH$  with 2 moles  $TiCl_3$  and subsequent acidification of the filtrate give *dihydronorbixin* (VII),  $C_{24}H_{30}O_4$ , which sinters at 197°. Under similar conditions I is converted into *dihydrobixin* (VIII),  $C_{25}H_{32}O_4$ , m. 207-8°. Excess of  $TiCl_3$  in the reduction of I yields *perhydrobixin* (IX),  $C_{25}H_{40}O_4$  (?), which may be methylated to give *perhydrobixin Me ester* (X),  $C_{26}H_{40}O_4$ , b.p. 3-4° 203-4°,  $d_4^{19} = 0.924$ . Conversion of perhydronorbixin into the chloride followed by treatment with concd. aq.  $NH_3$  yields *perhydronorbixin diamide* (XI),  $C_{24}H_{38}O_2N_2$ , m. 111°. XIV. **Zeaxanthin, a new carotinoid pigment in maize.** P. KARRER, H. SALOMON AND H. WEHRLI. *Ibid* 790-2(1929).—Prolonged extrn. of maize with EtOH, subsequent treatment with petroleum ether, removal of fats by sapon., purification of the residues with  $Et_2O$  followed by crystn. from petroleum ether yields a new natural xanthophyll pigment, *zeaxanthin*,  $C_{40}H_{56}O_2$ , m. 201-2°.

**Bixin. V.** I. J. RINKES. *Rec. trav. chim.* 48, 603-6(1929); cf. *C. A.* 23, 101.—On ozonization of methylbixin R. had obtained previously a cryst. degradation product  $C_8H_{10}O_3$ , which he supposed to be Me 1-formyl-2 or 3-methyl-1,3-pentadienecarboxylate (I), while the compd. obtained from I by oxidation and sapon., was regarded as *trans-β-methylmuconic acid* (*Chem. Weekblad* 25, 564(1928)). The correctness of this supposition is now proved by oxidation of I with  $Ag_2O$  and sapon. of the oxidation product to a *β-methylmuconic acid*, m. 229°. The same product was also obtained on heating *cis-cis-β-methylmuconic acid* for 5 hrs. with concd. alkali and thus the structure of I, except for the position of the Me group, is proved as well as its *trans*-configuration. The *β-methylmuconic acid* of Pauly and Will (cf. *C. A.* 13, 573) is to be considered as the *cis-cis*-compd. because of its formation from a cyclic compd., 4,3- $HO(O_2N)C_6H_3Me$ , and because of the easy cyclization of its diurethan. For the degradation product  $C_8H_8O_2$  from bixin ozonide, R. had already put forward the structure of a methylfumaryl or methylmaleic dialdehyde (cf. *C. A.* 12, 472), which on hydrogenation should give methylsuccindialdehyde. The synthesis of the latter compd. was attempted in the following way: *cis-cis-β-methylmuconic diamide*, m. 218° (cf. Pauly and Will, *C. A.* 13, 573) was converted in MeOH suspension into *isoprene diurethan*, m. 160-1°, by means of NaOCl. On sapon. of this diurethan with 5%  $H_2SO_4$  methylsuccindialdehyde was not formed, ring closure taking place with the formation of *Me β-methylpyrrole-N-carboxylate*,  $b.p. 80^\circ$ , which on sapon. with alkali yields *β-methylpyrrole* and  $CO_2$ .

**Brasiliin and hematoxilin question. IX. Compounds of the phenoxyacetone series.** P. PREIFFER AND J. WILLEMS. *Ber.* 62B, 1242-50(1929); cf. *C. A.* 23, 150.—The work described in this paper is the 1st step in the direct synthesis of compds. of the brasiliin and hematoxilin series which still contain the alc. HO group of these 2 substances. Among the degradation products of trimethylbrasiliin (I), brasiliic acid,  $MeOC_6H_3.O.CH_2.C(OH)(CH_2CO_2H).CO$  (II), contains such a HO group. In order

to synthesize II, *γ-[m-methoxyphenoxy]citramalic acid*,  $m-MeOC_6H_4OCH_2C(OH)(CO_2H)CH_2CO_2H$  (III), was prepd. by condensing  $m-MeOC_6H_4OCH_2CO.Et$  (IV) and  $BrCH_2CO_2Et$  in the presence of amalgamated Zn to *Et γ-[m-methoxyphenoxy]acetoacetate* (V), adding HCN to form the corresponding *HO nitrile* (VI) and hydrolyzing the VI to III.  $PhOCH_2CO_2Et$  and  $PhCH_2CN$  in the presence of NaOEt gave the nitrile  $PhOCH_2COCH(CN)Ph$  (VII), converted by MeOH and HCl into the ester  $PhOCH_2COCH(CO_2Me)Ph$  (VIII), which gives no color with  $FeCl_3$  unless it is first melted and then dissolved in alc., when it at once gives a deep violet-red color. With boiling concd. HCl the keto ester is sapond. and splits off  $CO_2$ , giving 1-phenoxy-3-

phenylacetone (IX), which with HCN yields the *HO nitrile*  $\text{PhOCH}_2\text{C}(\text{OH})(\text{CH}_2\text{Ph})\text{CN}$  (X).  $\text{PhOCH}_2\text{COCH}_2\text{CO}_2\text{Et}$ , obtained in 2–3% yield from  $\text{PhOCH}_2\text{CO}_2\text{Et}$ ,  $\text{BrCH}_2\text{CO}_2\text{Et}$  and  $\text{Zn}$  in  $\text{C}_6\text{H}_6$ , faintly brown oil;  $\text{Cu}$  salt, light green, m. 155.5–6°; *p*-nitrophenylhydrazone, yellow, m. 136–7°. The ester (0.5 g.) with HCN in  $\text{Et}_2\text{O}$  gives 0.05 g. of the *HO nitrile* as a brownish oil. *Di-Me* [*m*-methoxyphenyl]malonate (22% (as the Na salt) from  $\text{PhOCH}_2\text{COCl}$  and  $\text{CHNa}(\text{CO}_2\text{Me})_2$  in  $\text{C}_6\text{H}_6$ ;  $\text{Cu}$  salt, green, m. 154.5°), m. 51.5–2.5°, gives an intense  $\text{FeCl}_3$  reaction. V (9 g. from 60 g. IV),  $b_{0.2}$  176°;  $\text{Cu}$  salt, green, m. 121°. VI, light yellow viscous oil, can be distd. in small amts. (0.5 g.) in a high vacuum, after addn. of a trace of  $\text{H}_2\text{SO}_4$ , without decompn.; benzoate, green-yellow oil, can be distd. without decompn. in a high vacuum. III, faintly brown viscous liquid purified through the *Ca* salt. *Di-Me* [(*m*-methoxyphenyl)acetyl]malonate (from [*m*-methoxyphenyl]acetyl chloride,  $b_{15}$  145–6.5°), m. 55–6°, gives an intense red color with  $\text{FeCl}_3$  and instantly decolorizes  $\text{Br}$  water. [2,3-Dimethoxyphenyl]acetic acid, from 2,3-(MeO) $_2\text{C}_6\text{H}_3\text{OH}$  in  $\text{NaOH}$  with  $\text{ClCH}_2\text{CO}_2\text{H}$ , m. 102.5–3°; chloride,  $b_{12}$  162°, gradually decomp. on standing, condenses with  $\text{NCCHNaCO}_2\text{Me}$  in  $\text{C}_6\text{H}_6$  to *Me* [(2,3-dimethoxyphenyl)acetyl]cyanoacetate, m. 87–8°, gives an orange-red color with alc.  $\text{FeCl}_3$ . 1-Phenoxy-3-phenyl-3-cyanoacetone (VII), m. 126–7°, gives a moss-green color with alc.  $\text{FeCl}_3$ . *Me* 3-carboxylate (VIII), m. 75.5–6°. IX, m. 43–4°; phenylhydrazone, very unstable, faintly yellow to brown crystals, begins to sinter 65°, m. 94–6°; semicarbazone, m. 151–2°. X, softens about 83°, m. 94–5°. C. A. R.

**Constitution of anserine.** W. LINNEWEH, A. W. KEIL AND F. A. HOPPE-SEYLER. *Z. physiol. Chem.* 183, 11–8 (1929); cf. *C. A.* 23, 4233.—The formation of a  $\text{Cu}$  salt indicates the presence of a  $\text{CO}_2\text{H}$  group in anserine. Further evidence of  $\text{CO}_2\text{H}$  was obtained by esterification with  $\text{EtOH}$  and dry  $\text{HCl}$ . The product isolated was *anserine Et ester chloroplatinate*, m. 225–30°. The Van Slyke detn. on free anserine showed 1  $\text{NH}_2$ , and the  $\text{Ag}$  I method 1  $\text{NMe}$ . These observations, together with similarities in properties and the difference of  $\text{CH}_2$  in the empirical formulas, suggested that anserine might be a homolog of carnosine. The decompn. products finally obtained by hydrolysis proved the assumption to be correct. Distn. over soda lime in a current of  $\text{H}$  yielded 1,4-dimethylimidazole, isolated as the chloroaurate, m. 220–5°. Hydrolysis with  $\text{Ba}(\text{OH})_2$  6 hrs. at 140° yielded *dl*-methylhistidine, decomp. 248–52° with foaming (*nitrate* decomp. 144–6° with foaming), and  $\beta$ -alanine, isolated by means of the  $\alpha$ - $\text{C}_{10}\text{H}_7\text{NCO}$  deriv. The negative diazo reaction of anserine and its decompn. products, dimethylimidazole and methylhistidine, places the  $\text{Me}$  on the  $\text{N}$  of the ring. Anserine is, therefore,  $\beta$ -alanylmethylhistidine. As a methylated condensation product of histidine it presents a certain analogy to creatinine, which is a methylated cleavage product of arginine, both contg. the imidazole ring. A. W. DOX

**The action of formic acid on hydroxy- and chlorohemin.** A. HAMSKE. *Z. physiol. Chem.* 183, 103–12 (1929).—When hydroxyhemin is dissolved in  $\text{MeOH}$  contg.  $\text{KOH}$ , the soln. poured into an acid ( $\text{CH}_2\text{O}_2$ ,  $\text{AcOH}$ , alc.  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{C}_2\text{H}_5\text{O}_4$ ), and immediately dild. with  $\text{H}_2\text{O}$ , the original substance is reprecipitated. Formation of the corresponding hemin deriv. requires a longer contact with the concd. acid. Chlorohemin is formed the most rapidly, then formylhemin, then acetylhemin, while oxalyl- and sulfate-hemin are the slowest to form. Hence the prepn. of chloro- and formylhemin is the easiest, and that of the others the most difficult and incomplete. These hemins may be obtained directly from blood or indirectly from hydroxyhemin. From oxyhemoglobin or from hydroxyhemin K the pigment can be extd. by acids without alteration of its original  $\alpha$ -modification. Linkage to K protects the pigment group in the same way as linkage to globin. The extn. is best performed by means of  $\text{EtOH}$  or  $\text{AcMe}$  contg.  $\text{C}_2\text{H}_5\text{O}_4$ . Extn. by  $\text{CH}_2\text{O}_2$  in place of  $\text{C}_2\text{H}_5\text{O}_4$  gives a poorer yield, while  $\text{H}_2\text{SO}_4$  tends to alter the pigment. Although oxyhemoglobin and hydroxyhemin K may be extd. with acid solvents, dry hydroxyhemin should not be so treated because the  $\alpha$ -modification thereby becomes altered. To obtain an acid soln. the hydroxyhemin is first dissolved in  $\text{MeOH-KOH}$  and this soln. poured into acid. Chlorohemin, however, can be obtained directly from hydroxyhemin by boiling with  $\text{AcOH}$  and  $\text{NaCl}$ . Likewise formylhemin can be obtained directly by placing freshly prepd. hydroxyhemin in  $\text{CH}_2\text{O}_2$ . But the  $\text{CH}_2\text{O}_2$  must be properly dild. if the conversion of hydroxyhemin into a pseudo form is to be avoided. The pseudo form on removal of  $\text{Fe}$  yields a pseudoporphyrin, instead of protoporphyrin.  $\text{MeAc-chlorohemin}$ , when boiled with 95%  $\text{CH}_2\text{O}_2$ , is converted into a pseudo modification, but 80%  $\text{CH}_2\text{O}_2$  dissolves it less readily and causes less alteration. However,  $\text{MeAc-chlorohemin}$  dissolved in pyridine- $\text{CHCl}_3$  is more sensitive to  $\text{CH}_2\text{O}_2$ .  $\text{AcOH-chlorohemin}$  is more resistant. The protoporphyrin is purer when obtained by 85% than by 95% acid; in the latter case there is formation of pseudoporphyrin and pseudohematin. A. W. DOX

**The bile acids. XXIV. Two new hydroxamic acids derived from bilianic acid, and the action of nitric acid on  $\alpha$ -diketocholanic acid dioxime.** MARTIN SCHENCK AND HENRY KIRCHHOF. *Z. physiol. Chem.* 183, 88-97(1929); cf. *C. A.* 23, 2985.—Treatment of  $\alpha$ -diketocholanic acid dioxime with  $\text{HNO}_3$  does not yield the expected hydroxamic acid but splits off both oxime groups and opens up ring I, with formation of desoxybilianic acid. It is possible, however, that the hydroxamic acid is first formed and immediately undergoes hydrolysis. On the other hand, from the nitrohydroxamic acid,  $\text{C}_{24}\text{H}_{44}\text{N}_2\text{O}_9$ , obtained from the trioxime of dehydrocholic acid and  $\text{HNO}_3$  and described in the previous paper, 2 new hydroxamic acids were prepd. The 1st was obtained by reduction with Zn dust and  $\text{NH}_4\text{OH}$ . It is an *oximinohydroxamic acid*,  $\text{C}_{24}\text{H}_{44}\text{N}_2\text{O}_8$ , decomps.  $224-6^\circ$ , and represents simply a reduction of the  $\text{NO}_2$  group in the mother substance. It gives an intense reddish violet color with  $\text{FeCl}_3$ . Oxidation of this oximino deriv. with  $\text{HNO}_3$  gave a product identical with the nitroso compd. previously obtained from the mono- and dioxime of bilianic acid. The reaction that occurred was, therefore, a splitting off of the hydroxamic acid group. This explains also the failure to isolate the intermediate hydroxamic acid in the oxidation of diketocholanic acid. The 2nd *hydroxamic acid*,  $\text{C}_{24}\text{H}_{44}\text{NO}_8$ , decomps.  $225^\circ$ , was obtained by partial hydrolysis of the oximino deriv. by  $\text{HCl}$ . The reaction here is simply a splitting off of  $\text{NH}_2\text{OH}$ , leaving a CO group at  $\text{C}_{12}$ . The product gives a cherry-red color with  $\text{FeCl}_3$ . Further hydrolysis of this hydroxamic acid, or complete hydrolysis of the oximino deriv., yields bilianic acid. A. W. Dux

**Catalytic oxidation of organic compounds.** ALPHONS O. JAEGER (to Selden Co.) U. S. 1,722,297, July 30. See Brit. 296,071 (*C. A.* 23, 2185).

**Organic thiocyanate compounds.** I. G. FARBERIND. A.-G. Brit. 303,813, Sept. 5, 1927. The thiocyanate group is introduced into org. compds. by treatment with a halogen (suitably Br) and an inorg. thiocyanate (suitably that of Na, K or  $\text{NH}_4$ ) in the presence of a neutral org. solvent such as MeOH in which all the reacting substances dissolve. Examples are given.

**Chlorination products of hydrocarbons.** EWALD SPER. U. S. 1,721,873, July 23.  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ , or other satd. hydrocarbon, in the gaseous state, and Cl gas in sufficient quantity to produce the desired deriv. are allowed to react at a proper temp. in a chamber filled with small pieces of graphite.

**Chlorinating methane.** KOLOMAN ROKA (to Holzverkohlungs-Industrie A.-G.) U. S. 1,723,442, Aug. 6.  $\text{CH}_4$  is chlorinated in the presence of steam as a diluent at a temp. of  $400-500^\circ$  and the temp. is kept below the point at which substantial quantities of oxides of C would be formed.  $\text{CH}_3\text{Cl}$  is formed.  $\text{CaCl}_2$ ,  $\text{CuCl}_2$ ,  $\text{MgCl}_2$ , or  $\text{FeCl}_3$  may be used as catalysts. Cf. *C. A.* 23, 4228.

**Diolefins.** I. G. FARBERIND. A.-G. Brit. 303,323, April 30, 1928. Diolefins such

as butadiene and its homologs are sepd. from gas mixts. by treatment with a salt (preferably in soln.) of a heavy metal from the 1st or 2nd group of the periodic system. Various details and examples are given. Cf. C. A. 23, 4228.

**Olefins and diolefins.** I. G. FARBENIND. A.-G. Brit. 303,998, Dec. 14, 1927. Olefins and diolefins are obtained by catalytic treatment in a vaporous state of paraffins, olefins, or mixts., which may be cyclic, at 500–800°, using as catalyst lustrous C which is deposited from hydrocarbons at temps. above 650°. Various carriers, auxiliary catalysts, details of procedure, etc., are described. Cf. C. A. 23, 2722.

**Aldehydes and ketones.** MARTIN LUTHER and KURT PIEROH (to I. G. Farbenind. A.-G.). U. S. 1,723,458, Aug. 6. In recovering aldehydes and ketones formed by the catalytic dehydrogenation of alcs. contg. at least 3 C atoms, the alc. used in the dehydrogenation is used for absorbing the dehydrogenation product from the assocd. gas mixt.

**Aromatic aldehydes.** PARFUMERIE HOUBIGANT (S. A.) and LÉONCE BERT. Fr. 657,691, Dec. 2, 1927. Aldehydes of the phenylacetic series and homologs of phenylacetic aldehyde are obtained by condensing the Mg compds. of Cl derivs. such as  $R_3C_6H_4$ ,  $CH_2Cl$ ,  $R_3C_6H_4Cl$ ,  $R_3C_6H_4Cl$ , with Me or Et formate, whereby acetates are formed which pass easily to the aldehydes. An example is given of the prepn. of 1,4-dimethylphenylacetic aldehyde ( $b_p$  104–105°) from the Mg compd. of 3,4-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CH<sub>2</sub>Cl and HCOOEt. Several other examples and examples of the prepn. of the Mg compds. are given.

**Esters.** HOLZVERKOHUNGS-IND. A.-G. Fr. 657,812, July 19, 1928. See Brit. 295,275 (C. A. 23, 2187).

**Aminophenol ethers.** ERNST F. GREYER (to Dow Chemical Co.). U. S. 1,722,417, July 30. In prepg. aminophenol ethers such as *p*-ethoxyphenylamine, an arylamine such as aniline is diazotized, coupled with a phenol such as PhOH, alkylated, *e. g.*, with EtBr, and the product is subjected to reduction by heating with Fe and an Fe salt such as the acetate in the presence of water.

**Carbazole derivatives.** I. G. FARBENIND. A.-G. Brit. 303,520, Jan. 5, 1928. Substitution products of carbazole are formed by subjecting the diazo compds. of aminocarbazoles (other than 3-aminocarbazole) to reactions such as are customarily employed in treating aromatic amines. Examples are given of the production of 1- and 2-hydroxycarbazoles, 2-chlorocarbazole, 2-cyanocarbazole, carbazole-1-carboxylic acid and carbazole-2-sulfinic acid (which may be oxidized to the sulfonic acid or reduced to the mercaptan or disulfide), etc. Cf. C. A. 23, 3715.

**Ethylene derivatives.** COMPAGNIE DE BETHUNE. Brit. 303,176, Dec. 29, 1927. Coal distn. gases are treated to sep. a mixt. of C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>6</sub> and the C<sub>2</sub>H<sub>4</sub> is absorbed in H<sub>2</sub>SO<sub>4</sub>, and the C<sub>2</sub>H<sub>6</sub> is heated to produce C<sub>2</sub>H<sub>4</sub> and H which are returned to the raw gas whence the C<sub>2</sub>H<sub>4</sub> formed is subsequently recovered. The EtHSO<sub>4</sub> is then worked up into desired products such as EtOH or glycol, ether, etc. An app. is described.

**Dimethylaminopentanol derivatives.** ÉTABLISSEMENTS POULENC FRÈRES, ERNEST FOURNEAU and JACQUES TREFOUËL. Fr. 657,931, Dec. 6, 1927. *m*-Nitrobenzoyldimethylaminopentanol is prepd. by heating to about 50° dimethylaminopentanol with *m*-nitrobenzoyl chloride in soln. in C<sub>6</sub>H<sub>6</sub>. This compd. is reduced by SnCl<sub>2</sub> and HCl. M. p. of the HCl compd. is 189°.

**Diazo compounds.** KALLE & Co. A.-G. Fr. 657,852, July 20, 1928. See Brit. 294,248 (C. A. 23, 1908).

**Morpholine compounds.** IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 657,860, July 20, 1928. See Brit. 298,336 (C. A. 23, 2723).

**Substituted guanidines.** I. G. FARBENIND. A.-G. Brit. 303,044, Sept. 26, 1927. See Fr. 640,017 (C. A. 23, 847).

**Monocyclic lactones.** SOC. ANON. M. NAEF & CIE. Fr. 657,971, July 23, 1928. Monocyclic lactones having 14 to 18 links are obtained by heating with monopersulfuric acid to 30–60° monocyclic ketones having 13 to 17 links. Examples are given of the prepn. of the lactone of 14-hydroxytetradecane-1-carboxylic acid (m. 31–32°,  $b_p$  176°), the lactone of 12-hydroxydodecane-1-carboxylic acid (m. 26–27°,  $b_p$  148°), the lactone of 13-hydroxytridecane-1-carboxylic acid (m. 29–30°,  $b_p$  165°), the lactone of 15-hydroxypentadecane-1-carboxylic acid (m. 35–36°,  $b_p$  188°), the lactone of 16-hydroxyhexadecane-1-carboxylic acid (m. 41–42°,  $b_p$  194°), and the lactone of 14-hydroxymethyltetradecane-1-carboxylic acid ( $b_p$  180°).

**Catalytic hydrogenation of nitroenous compounds.** I. G. FARBENIND. A.-G. Brit. 304,000, Dec. 20, 1927. Hydrogenation of open-chain compds. contg. N in unsatd. union is effected in the liquid phase in the presence of a hydrogenating catalyst and of an electrolyte supplying acid ions in quantity at least equiv. to the base produced; *e. g.*,

KCN in aq. soln. is hydrogenated with the aid of a Ni catalyst in the presence of  $\text{FeSO}_4$  to produce methylamine. Various other examples are given.

**Chloriodides of 2-aminopyridine salts.** MAX DOHRN and RALPH DIRKSEN (to Chemische Fabrik auf Actien, vorm. E. Schering). U. S. 1,723,457, Aug. 6. When ICl is allowed to act in acid soln. on  $\alpha$ -aminopyridine and its derivs., there are formed pptts. which are insol. in acids and which are salts of the ICl compds. of  $\alpha$ -aminopyridine or its derivs. In the majority of cases these salts are well crystd. and substantially stable. They are not decomposed when boiled in acid soln. and, on cooling such a soln., sep. as crystals. All these compds. are capable of forming in alk. soln. the corresponding  $\beta$ -iodo derivs. of the base. Several examples are given.

**Indoles.** I. G. FARBENIND. A.-G. Brit. 303,467, Oct. 4, 1927. Substituted indoles are prepd. by heating a monoacylamino compd. of the aromatic series having a Me group in the *o*-position, such as aceto-*o*-toluidine, with sodamide in the presence of a diluent such as naphthalene, dimethylaniline or diethylaniline. Various examples are given.

**Converting cyanonaphthalenesulfonic acids.** RICHARD HERZ, FRITZ SCHULTE and WERNER ZERWECK (to Grasselli Dyestuff Corp.). U. S. 1,721,882, July 23. When cyanonaphthalenesulfonic acids, contg. at least one sulfonic group in *o*- or *p*-position to the cyano group, are treated with an alk.-acting agent at elevated temps. this sulfonic group, standing in *o*- or *p*-position to the cyano group, is easily exchanged for other univalent radicals. The products thus obtained correspond to the general formula,  $\text{C}_{10}\text{X}_6(\text{OY})\text{Z}$ , in which the group OY stands in *o*- or *p*-position to the group Z, the X's mean H atoms, of which one or more may be replaced by a univalent substituent, Y means H or an alkyl residue, Z the groups CN,  $\text{CONH}_2$  and  $\text{COOH}$ . By acting with milder alk. agents, the cyano group of the cyanonaphthalenesulfonic acids remains unattached and hydroxycyanonaphthalene compds. are formed corresponding to the above formula, Y being H and Z being CN; by acting with stronger alk. agents the cyano group is saponified to the carboxamido or to the carboxy group whereas the sulfonic group is exchanged by hydroxyl, when the applied alk. agent is an aq. caustic alkali, or by an alkoxy group, generally when applying caustic alkalies in the presence of an alc. In this manner alkoxynaphthalenecarboxamides and hydroxy- and alkoxynaphthoic acids are obtained corresponding to the above formula. Various details and examples are given. Cf. C. A. 22, 3170.

**Anhydrous formic acid.** SOC. ANON DES DISTILLERIES DES DEUX-SEVRES. Brit. 303,742, Jan. 7, 1928. Aq. formic acid is distd. with an "entraining" material such as iso-Bu formate, capable of forming with water an azeotropic mixt. of minimum b. p., and with a diluent liquid such as Am formate which prevents the formic acid from distg. over with the azeotropic mixt. The resulting mixt. of formic acid and diluent may be sepd. by fractional distn. or distn. with entraining substances such as  $\text{C}_6\text{H}_6$ , toluene, xylene, certain petroleum hydrocarbons, BuCl and chlorinated derivs. of  $\text{C}_2\text{H}_4$  and  $\text{C}_2\text{H}_2$ . Formic esters, such as Bu, Am, and iso-Am formates, or di-Bu ether, may serve both as "entrainer" and as "diluent." An app. is described.

**Glacial acetic acid.** AYLMEYER H. MAUDE (to Rubber Service Laboratories Co.) U. S. 1,722,532, July 30. HOAc contg. about 10% water is concd. in a single-stage distn. by heating with about 20% its volume of  $\text{C}_6\text{H}_6$ .

**Aliphatic anhydrides.** HENRY DREYFUS. Fr. 657,604, July 17, 1928. Aliphatic anhydrides, particularly  $\text{Ac}_2\text{O}$ , are prepd. by the reaction of liquid aliphatic acid and (or) metallic salts of such acids with phosphoric acid having a degree of hydration less than that of  $\text{H}_2\text{PO}_4$  and (or) with salts of such phosphoric acid. The temp. used is preferably 150-180°.

**Aliphatic anhydrides.** HENRY DREYFUS. Fr. 658,111, July 26, 1928. Aliphatic anhydrides, particularly  $\text{Ac}_2\text{O}$ , are prepd. by passing the vapor of the aliphatic acid through a reaction zone composed of or contg. one or more reducible metals such as Cu, Ni or Sn and heated to a relatively high temp. (500-700°), H or another reducing gas being passed through the reaction zone during the passage of the acid and (or) before this passage. Cf. C. A. 23, 4230.

**Acetic anhydride, etc.** BRITISH CELANESE, LTD., H. DREYFUS and C. I. HANEY. Brit. 303,772, July 7, 1927. Anhydrides such as  $\text{Ac}_2\text{O}$  are produced by heating the vapors of the corresponding acid (which may be dil.) and are condensed while carrying away the water by the vapor of an "entraining liquid" such as  $\text{CCl}_4$ , "petrol," benzene, mixts. of 2 or more of these substances, or mixts. of ether with "petr. ether" (but avoiding liquids which are solvents for the anhydride and have a b. p. higher than the b. p. of water). Various details are given and an app. is described.

**Methanol.** COMMERCIAL SOLVENTS CORP. Fr. 34,361, June 21, 1927. Addn. to

635,023. A catalyst for the synthesis of MeOH from CO and H is prepd. by combining ZnO, Cr(NO<sub>3</sub>)<sub>3</sub>, Fe(NO<sub>3</sub>)<sub>3</sub>, and ZnCl<sub>2</sub> in aq. mixt. and transforming the nitrates into oxides. Cf. C. A. 23, 1910.

**Isoeugenol.** T. S. CARSWELL (to Graesser Monsanto Chemical Works., Ltd.). Brit. 303,021, Dec. 22, 1927. The mixt. of alkoxyisoeugenol and alkoxyisochavibetol, such as may be obtained by heating safrol or isosafrol with alc. KOH under pressure, is sep'd. by utilization of the difference in the solubilities of their Ca salts in alc. (the Ca salt of the alkoxyisochavibetol being the less sol.). The sep'd. alkoxyisochavibetol may be methylated and then hydrolyzed to produce isoeugenol. Various details of procedure are given.

**Dinitrophenol.** DONALD B. BRADNER and FRANK H. BEALL. U. S. 1,723,761, Aug. 6. In effecting reaction of HNO<sub>3</sub> and C<sub>6</sub>H<sub>6</sub> in the presence of a Hg catalyst, the reacting mass is agitated and the reaction is carried out in the presence of an aliphatic acid such as HOAc which considerably increases the soly. of the C<sub>6</sub>H<sub>6</sub> in the HNO<sub>3</sub> and accelerates the reaction without being itself consumed. An app. is described.

**Alkylisopropylphenols.** CHEMISCHE FABRIK AUF ACTIEN (VORM. F. SCHERING). Fr. 34,369, Oct. 21, 1927. Addn. to 636,267 (C. A. 23, 156). The mixt. of alkylisopropylphenols and alkylcumarones described in Fr. 636,228 (C. A. 23, 156) and 638,483 (C. A. 23, 154) is first hydrogenated by H and a catalyst until 2 to 8 H atoms are fixed, and the mixt. of hydrogenated products is then sep'd.

**1-Phenyl-3-methyl-5-pyrazolone.** HANS FINKELSTEIN and HANS HAUBER (to J. G. Farbenind. A.-G.). U. S. 1,723,545, Aug. 6. See Brit. 274,366 (C. A. 22, 1983).

**Polymerized formaldehyde.** I. G. FARBENIND. A.-G. Brit. 303,258, Dec. 2, 1927. Solid polymers of CH<sub>2</sub>O are prep'd. by treating an aq. soln. of CH<sub>2</sub>O with a small quantity of an alk. reagent such as Na<sub>2</sub>CO<sub>3</sub> or NaOH without using gelatinizing agents such as soaps or similar substances. The soln. should be free or nearly free from MeOH.

**$\alpha$ -Naphthylamine from mixed  $\alpha$ - and  $\beta$ -naphthylamines.** HENRY J. WEILAND and IVAN GUBELMANN (to Newport Co.). U. S. 1,722,026, July 23. Sufficient acid such as HCl is added to the mixt. in a dispersion medium such as water to convert substantially all the  $\beta$ -naphthylamine into its corresponding salt dissolved in the dispersion medium, and the  $\alpha$ -naphthylamine in solid form is sep'd. from the soln. thus formed.

**Camphene from pinene hydrochloride.** HERMANN GAMMAY. U. S. 1,721,990, July 23. Pinene hydrochloride is reacted on with less than a stoichiometrically equiv. proportion of a converting agent such as PhOH or oleic acid and the consumed part of the converting agent is regenerated by an alk. comp'd. such as NaOH in a continuous operation.

**Cuprene.** N. V. ELECTRO-ZUURSTOF-EN-WATERSTOFFFABRIEK. Brit. 303,797, Jan. 9, 1928. Cuprene having such adsorbent properties that it is suitable for use instead of charcoal for decolorizing or deodorizing liquids, etc., is obtained by treating C<sub>2</sub>H<sub>2</sub> with a metal or metal-oxide catalyst such as the oxides of Cu, Ni or Fe, or these metals themselves, to which a small proportion of Mg is added. A temp. of 200–400° is suitable and cuprene free from the usual metals may be used with a small addn. of Mg as a catalyst for producing more cuprene. The Mg may be removed from the product with acid and the product may be used for decolorizing blue "methylated spirit" or for cleaning dirty water.

**Ketene.** HANS T. CLARKE and CHARLES E. WARING (to Eastman Kodak Co.). U. S. 1,723,724, Aug. 6. Vapors such as those of acetone which are decomposed by heat into substances including ketene are passed through a chamber contg. a network of metal such as Cu (free from Fe or Ni) having high thermal cond. and a m. p. above the reaction temp. (which may be about 650–670°).

**Styrene.** THE NAUGATUCK CHEM. CO. Fr. 657,990, July 23, 1928. See U. S. 1,687,903 (C. A. 23, 156).

## 11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

**Colloid chemistry of cerebrospinal fluid.** J. KISS. *Deut. Z. Nervenheilk.* 98, 227–72 (1927).—Cerebrospinal fluid is best studied by means of gold sol. B. C. A.

**Enzymic fission of sucrose.** II. R. WEIDENHAGEN. *Z. Ver. deut. Zucker-Ind.* 78, 781–7 (1928); cf. C. A. 23, 3237.—Of the two sucrose-splitting enzymes in

yeast, *viz.*,  $\alpha$ -glucosidase and  $\beta$ -*h*-fructosidase, the former is present in much smaller quantity than the latter and is inactive at  $p_H$  4.7, the optimum reaction for fructosidase. Their behavior toward raffinose affords a means of distinguishing them, since  $\alpha$ -glucosidase has no action, while the fructosidase produces melibiose and levulose. *Melezitose*, a glucosidofructosidoglucose in which the fructosidoglucose portion of the mol. is supposed to have the constitution of sucrose, is not attacked by fructosidase, but is completely hydrolyzed to hexoses by  $\alpha$ -glucosidase; hence it appears to be  $\alpha$ -glucosido- $\beta$ -*h*-fructosido- $\alpha$ -glucoside.

**Specificity of enzymic fission of maltose.** R. WEIDENHAGEN. *Z. Ver. deut. Zucker-Ind.* 78, 788-95(1928); cf. *C. A.* 23, 3237.—Leibowitz has assumed the existence of 2 types of maltase, *viz.*, glucosido-maltase present in yeast, and gluco-maltase present in barley and in takadiastase, the latter type being incapable of hydrolyzing  $\alpha$  methyl-glucoside or maltosazone (cf. *C. A.* 20, 211, 3173). This view is not shared by the author, who found that  $\alpha$ -methylglucoside is readily hydrolyzed by barley maltase if sufficiently concd. enzyme solns. are used. The fact that maltase in different materials may exert its max. activity at different  $p_H$  values does not disprove the identity of the enzyme in the different materials, since the effect of activating and inhibiting substances has to be considered.

**Study of glucosides by means of enzymes.** MILLE BRÄCKE. *J. pharm. Belg.* 10, 463-6, 479-82, 495-8(1928).—The method of study is based on the specificity of the enzymes. The enzymes are used as reagents revealing the principles on which they exert their action. The study is divided into the following divisions: 1. *Saccharose detected by invertin.*—Invertin acts on certain polysaccharides, as raffinose and gentianose, by releasing *d*-fructose or levulose from the remainder of the sugar mol. The invertin is prepd. from bakers' yeast. The glucoside is obtained by extg. with 90% alc., which destroys the action of the enzymes, and  $\text{CaCO}_3$  is used for the neutralization of the plant acids. The glucoside-contg. soln. is polarized, invertin then added, and again polarized. From the readings, the index of enzymolytic reduction is obtained. This index is the wt. in mg. of reduced product, expressed as glucose, found in 100 cc. of the soln. under the action of invertin, causing a change of  $1^\circ$  in rotation, and using a 200-mm. tube. The application of this method revealed the presence of saccharose in numerous plants, its variation as reserve in these plants, and the more frequent occurrence of raffinose and stachyose. It also led to the discovery of *verbalucose*. 2. *Trehalose of the fungus by trehalase.*—Trehalase divides the biglucide into 2 mols of *d*-glucose. The method of prepg. a soln. from *Aspergillus niger* is more suitable for biochem. analysis than the previous method of Bourquelot. It permits detections in certain species, in which the old method was useless. The trehalose exists in the fresh fungi; it disappears upon desiccation, being transformed into glucose and some mannitol.  $\text{CHCl}_3$  prevents the formation of mannitol, but not of glucose. It is best to prep. the soln. by boiling in alc. as soon as possible after collecting. The presence of trehalose is essential to all mushrooms. 3. *Heteroglucosides derived from d-glucosidase  $\beta$  by emulsin.*—The active element can be called glucosidase  $\beta$ . The emulsin is prepd. by extg. crushed almonds with  $\text{CHCl}_3$  water, pptg. the plant casein with  $\text{AcOH}$ , then the emulsin with alc. and finally drying over  $\text{H}_2\text{SO}_4$ ; yield 1.5%. The test is carried out on the soln. remaining after the action of invertin, by first heating on a water bath to destroy the invertin; then adding emulsin, incubating and polarizing. This method permits the detection of heteroglucosides, their detn. in the various plants and the detection of the alteration of plants during desiccation, and during the prepn. of pharmaceutical products. 4. *Sinigrin by myrosin.*—Myrosin liberates *d*-glucose from complexes contg. sulfated bases. The myrosin is prepd. by macerating white mustard with water, expressing, pptg. the mucilages with 80% alc., and finally pptg. the enzyme with 90% alc. In the transformation of the sinigrin, neutralize the acid sulfate formed by means of  $\text{K}_2\text{CO}_3$ . No new glucoside has yet been found in this class. 5. *Glucosides detected by means of a fermenting substance obtained from the plant.*—The principle in this case is of a general order. If it cannot be applied to all glucosides, it is due to the absence of the corresponding enzyme. The fermenting powder is made by extg. the plant with strong alc. The alc. is first used to ext. the principles and then to ppt. the enzymes. Dry at a low temp., polarize, and test for reducing substances. Geoside and grease, having an eugenol base, are given as examples. 6. *Glucosides hydrolysed by rhamnodiastase.*—Rhamnodiastase is prepd. by extg. the grains of *Rhamnus utilis* Dene. with  $\text{Et}_2\text{O}$  for the removal of oil and coloring matter, then extg. with thymol water, pptg. the enzyme with 95% alc., washing and drying. The rhamnodiastase is less sp. than emulsin, which the latter sometimes resembles in its action. Rhamnodiastase also acts upon some glucosides insol. in water, and some that are pptd. by

lead ext. The amt. used in a test is 0.05–0.10 g. per 100 cc. of soln., under which conditions the enzyme is inactive with respect to glucosides hydrolyzed by emulsin. The glucosides acted upon are divided into classes depending upon one of the end products: (a) *Primeverosides*.—These are further divided into 5 subdivisions depending upon the aromatic principle. All of them form primeverose; the aromatic principle is methyl salicylate or a deriv. The primeverose is a diose composed of xylose and glucose. (b) *Rutinosides*.—Datiscoside and rutoside form rutinose and are found in 16 families of the dicotyledons. Rutinose is a rhamnoglucose. (c) *Rhamninoside*.—Rhamninoside or xanthorhamnoside, found in yellow berries, splits to form rhamnetol and rhamnose. The latter splits further to form rhamnose and galactose. (d) *Robinoside*, found in *Robinia pseudoacacia*, splits to form kaempferol (1,3,4-trihydroxyflavonol) and a triose, robinose, which is isomeric with rhamnose. (e) *Glucosides*, the study of which is not complete, include a polydatoside, obtained from *Polygonum cuspidatum*, hydrolyzing to form polydatogenol and a levo-sugar; and ulexoside from *Ulex europaeus* forming a sugar and ulexogenol, m. 261°. The polydatogenol is equally acted upon, but more slowly, by emulsin, giving the same end products as rhamnodistase. Another case of similar effects is found with one of the primeverosides, which when classified as a  $\beta$ -glucoside easily explains the matter. The difference between the two is that the primeverosides hold the glucose combined with xylose as primeverose. For all the 6 classes, a bibliographic list of glucosides belonging to that class, with their source and discoverer, is given. B. also gives a late classification of the glucosides and glucoses

A. G. DUMKZ

The organic matter of sea water and its relation to plankton production. H. H. GRAN and BR. RUND. *Avhandl. Norske Vidensk. Akad. Oslo 1926; Intern. Rev. ges Hydrobiol. Hydrograph.* 19, 340(1928); *Wasser u. Abwasser* 25, 225.—The use of  $\text{KMnO}_4$  to det. the org. content of filtered and unfiltered sea water by oxidation was studied. The method is unreliable in giving the true org. content of unfiltered water because of the plankton organisms and bacteria present.

C. R. FELLERS

The coagulation of proteins of bovine endocrine glands. A. JANEČEK. *Biol. sp. zverolék.* 6, 269–81(1927). (Czech, with English summary); *Physiol. Abstracts* 13, 662.—The coagulability of proteins from bovine thyroid, thymus, suprarenals, pituitary body, and sexual glands differs from that of proteins from other organs. The typical precipitants of proteins of the endocrine glands are  $\text{CuSO}_4$  and sulfosalicylic acid.

Buffer intensities of milk and milk constituents. I. The buffer action of casein in milk. F. O. WHITTIER. *J. Biol. Chem.* 83, 79–88(1929).—Max. buffering in normal milk occurs at approx.  $pH$  5.50. The buffer action of casein is exerted principally between  $pH$  4.50 and 5.70 with a max. at approx. 5.2 so that casein is evidently one of the chief factors in the buffer action of milk in this range. The buffer intensity curves of purified caseins indicate that differences in methods of isolation and purification produce caseins differing from one another and from casein as it exists in milk. The addition of rennet to milk causes a disappearance of the pronounced node in the buffer intensity curve; apparently rennet converts casein into a substance with several dissociation consts. within the range of  $pK$  values from 4.0 to 7.5

A. P. LOTHROP

The presence of aluminum in animal and plant matter. LOUIS KAHLBERG and JOHN O. CLOSS. *J. Biol. Chem.* 83, 261–4(1929).—The materials were ashed in Pt dishes at dull red heat and the ash was examd. with a Kriess quartz-prism spectrograph. In every substance analyzed Al was found in sufficient quantity to be detected with certainty with the spectrograph. "It is clear, then, that Al is actually present in plant and animal matter and that the conclusion of McCollum, Rask and Becker ('*A.* 22, 3198) that 'Al is not a constituent of either plant or animal matter' is founded upon error and cannot be maintained."

A. P. LOTHROP

Enzymic proteolysis. V. The structure of animal skeletal substance. ERNST WALDSCHMIDT-LEITZ and GUSTAV V. SCHUCKMANN. *Ber.* 62B, 1891–6(1929).—Keratin was split by treating 24 g. of hair for 4 weeks with 24 g. of Br in 200 cc.  $\text{AcOH}$ . The insol. prepn. B was sepd. by centrifuging. Prepn. A pptd. upon adding  $\text{H}_2\text{O}$  to the supernatant liquid from the centrifuge. Both fractions were purified by dissolving weak  $\text{NaOH}$  and pptn. with  $\text{AcOH}$ . Fraction C, not pptd. by water, was obtained

by evapg. the filtrate from *B* to dryness. Fractions *A* and *B* were partly digested by trypsin but not by erepsin, while *C* was split slightly by erepsin. Analogous fractions were obtained by treating 10 g. of silk fibroin with 10 g. Br and 85 cc. AcOH. The residue thus obtained was sepd. by centrifuging. It was insol. in H<sub>2</sub>O and dil. NaOH. The supernatant liquid contained little N. Both the sol. and the insol. fractions were only slightly affected by trypsin and almost undigested by erepsin. A second series of products was prepd. from keratin by treating 20 g. of hair for 4 weeks with 24 cc. of perhydrol and 160 cc. of 4 *N* H<sub>2</sub>SO<sub>4</sub>. The residue was sepd. by centrifuging and purified by repptn. from weak NaOH with AcOH. The supernatant liquid from the centrifuge was freed from H<sub>2</sub>SO<sub>4</sub> with Ba(OH)<sub>2</sub> and evapd. to dryness. Twelve g. of silk fibroin was treated similarly. Both fractions from keratin were digested markedly by trypsin and considerably by erepsin. The analogous products from fibroin were almost unaffected by the same enzymes. "Peptones" were prepared from both fibroin and its compd. formed from reaction with perhydrol. Both "peptones" were attacked by trypsin and erepsin but the digestion was incomplete when compared with that obtained with H<sub>2</sub>SO<sub>4</sub>.  
C. M. McCAY

The soluble enzymes of the fungus *hymenomycetes*. The alkaloids and their antioxygen function. L. LUTZ. *Compt. rend.* 188, 1342-4(1929).—Alkaloids having a free phenol group decreased the velocity of oxidation of guaiacol and  $\alpha$ -naphthol by the mycelium *hymenomycetes*, but if the phenol group is substituted no effect is observable.  
J. G. McNALLY

The constant presence of phosphoglycerase in the enteric juice secreted by a Vella intestinal loop. A. CLEMENTI. *Boll. soc. ital. biol. sper.* 3, 1267-9(1928).—The enteric juice secreted by a Vella intestinal loop, either spontaneously or mechanically, or by stimulating with Liebig's extract. dil. HCl solns. or fatty acids and centrifuging, rapidly hydrolyzes the glycerophosphoric acid mol. in the presence of toluene at 37°. This hydrolyzing power disappears if the juice is previously boiled for one or two min.  
PETER MASUCCI

The coagulation of sodium soaps. M. CHIÒ. *Boll. soc. ital. biol. sper.* 4, 336-41(1929).—The conditions best adapted to produce soaps from fatty acids and oils are detd. The state and behavior of soaps in equil. and under conditions which approach those in blood are discussed.  
PETER MASUCCI

The hemolytic action of soaps. E. BALLICU. *Boll. soc. ital. biol. sper.* 4, 312-4(1929).—A very dil. soln. of Na oleate in Ringer soln. is by itself inactive in hemolyzing red blood corpuscles, but is activated by H<sub>2</sub>CO<sub>3</sub>, and this is again inactivated by heating to 60° for 30 min.  
PETER MASUCCI

The coagulation of milk [by soap]. M. CHIÒ AND S. REPETTO. *Boll. soc. ital. biol. sper.* 4, 345-9(1929).—Na oleate and Na stearate coagulate milk at different velocities and a mixt. of the two at a proportional velocity. Ca oleate, the Ca soap of butter fat, and Ca stearate modify the velocity of coagulation of milk. The oleate tends to retard, the stearate accelerates, and the soap made from butter fat which contains both radicals has an action somewhat intermediate.  
PETER MASUCCI

The isoelectric point of the proteins of the crystalline lens. N. SCALINCI. *Boll. soc. ital. biol. sper.* 4, 359-61(1929).—The isoelec. point of the proteins of the nuclear part of the lens is about *p<sub>H</sub>* 4.5; those of the proteins in the peripheral part are *p<sub>H</sub>* 3.5-4.0.  
PETER MASUCCI

The emission of ultra-violet rays by some phosphatides after irradiation. C. SERONO AND A. CRUTO. *Presse méd.* 36, 1158-9(1928); cf. *C. A.* 22, 4361; 23, 398.—*Lecithin* and *cerebrin* do not fluoresce during irradiation but later emit ultra-violet light. *Cholesterol* has a strong fluorescence, but no emission of light afterward. *Ergosterol* is weak in both.  
A. E. MEYER

Studies on iodine as a biogenous element. XII. The iodine content of normal animal organisms. E. MAURER AND H. DUCRUE. *Biochem. Z.* 193, 356-9(1928); cf. *C. A.* 21, 1299, 2296; Scharrer and Schwartz, *C. A.* 21, 3646.—The I<sub>2</sub> content of various tissues and organs from normal rabbits was found on the av.: thyroid, 15,800; ovary, 700; uterus, 100; spleen, 70; submaxillary, 65; hair, 30; heart, 20; kidney, 20; liver, 14; skin, 9; lung, 9; brain, 8; fat, 3  $\gamma$  %. Of the body fluids the following were examined: bile, 40; blood, 30; blood plasma, 40; blood cells, 21  $\gamma$  %. XIII. Effect of oral administration of small quantities of inorganic iodine on the iodine content of the animal organism. *Ibid* 360-3(1928).—The oral administration of inorganic iodine to rabbits produces a very large accumulation, especially in the organs of elimination (skin, lung, kidney), but after a period of 96 hrs. this is almost entirely gone. Daily administration of I<sub>2</sub> for therapeutic purposes is advocated in preference to administration at intervals. XIV. The effect on the blood iodine level of a single administration

of inorganic iodine. *Ibid* 364-71(1928).—The effect of  $I_2$  administration on the blood  $I_2$  is not uniform. In man the effect is entirely worn off after 24 hrs.; in rabbits and sheep the effect is more lasting, in the latter persisting for 6-11 days. The retention of  $I_2$  is not influenced by the activity of the thyroid gland. S. MORGULIS

The effect of water on the hydrogen peroxide-splitting capacity of barley malt catalase. II. M. O. CHARMANDARIAN. *Biochem. Z.* 207, 462-71(1929); cf. C. A. 23, 1922.—The catalase activity of malt is greater when water is added to it first, then  $H_2O_2$ . The amt. of  $H_2O_2$  decomposed is variable, depending upon the mol. of  $H_2O$  and the  $H_2O_2$  concn. The process of soln. of the catalase in  $H_2O$  is most rapid at the beginning and stops completely while the meal still contains much catalase. The addn. of toluene causes a small increase in the catalase reaction. The catalase in soln. undergoes inactivation, which is accelerated by high temp., light and stirring. Another property of catalase from barley malt. III. *Ibid* 207, 472-5(1929).—The catalase activity of malt is gradually lost. This process is much more rapid in the case of the meal than of the whole grain. The loss of the activity is, however, not a continuous process, and in the beginning is even interrupted by temporary increases. Malt preserved over  $H_2SO_4$  loses its catalase action very rapidly. In an atmosphere of  $CO_2$  the catalase disappears slower than in air. S. MORGULIS

The effect of electrolytes on glycerophosphatase. KENTARO INOUE. *J. Biochem. (Japan)* 10, 395-408(1929); cf. C. A. 23, 1427.—The activity of purified glycerophosphatase is inhibited only by F, oxalate and  $SO_4$  ions which are also anticoagulants for fibrinogen. Their interference with blood coagulation is ascribed to the fact that Ca ions are converted either to an insol salt or to an unionizable compd. However, the conception, that the glycerophosphatase inactivation may likewise be conditioned upon a removal of the Ca ion, meets with the serious difficulty that the various inhibiting ions exert a different effect at various degrees of acidity. S. MORGULIS

Phosphoric acid esters of sugar. CARL NEUBERG. *Wochschr. Brauw.* 46, 1-5 (1929).—A discussion with literature citations on phosphoric acid esters of sugar. A. SCHULTZ

Formation of diastase by *Aspergillus oryzae*. G. L. FUNKE. *Rec. trav. botan. Néerlandais* 24, 583-630; *Chem. Zentr.* 1928, II, 1444; cf. C. A. 21, 3927.—On buffered solns (addn. of 0.5%  $K_2HPO_4$ ) *Aspergillus oryzae* forms very large amts. of diastase, which are secreted into the fluid. In this process the chem. compn. of the nutritive soln. is without influence. Glucose, galactose, mannose, fructose, sucrose, maltose, lactose, starch, inulin, lichenin, glycerol and Ca lactate were examd. The amt. of diastase formed was the same with 5%, 1% or 0.5% carbohydrate soln. *Aspergillus* grows less on non-buffered solns.; it forms more acid and hardly any diastase; furthermore, anaerobic respiration occurs. The acid formed is probably oxalic acid, which possibly inactivates the enzyme by chem. union. G. SCHWOCH

Quantity of cysteine in living tissue proteins and its biological significance. YU-ZURU OKUDA. *Proc. Imp. Acad. (Japan)* 5, 246-8(1929).—A method is given for the detn. of cysteine in proteins under conditions avoiding oxidation. The cysteine and cystine contents of proteins were detd. as follows: muscle, hen, 0.818, 0.002%; carp, 0.856, 0.087; eel, 0.839, 0.026; lobster, 0.931, 0.027; liver, ox, 0.601, 0.382; hen, 0.517, 0.142; egg white, 0.683, 1.122; egg yolk, 0.322, 1.195; human hair, 0.440, 11.630. The O uptake of proteins, with and without the addn. of cystine or glutathione (disulfide), is also reported; fresh muscle protein shows a considerable increase in O absorption on addn. of these substances, while oxidized muscle protein and gelatin show no difference. This is taken to indicate that the SH group in fresh muscle protein or active tissue protein reduces cystine or glutathione into cysteine or reduced glutathione, which absorbs O. C. J. WEST

Oxidation by catalase. H. v. EULER, D. RUNEHJELM AND S. STEFFENBURG. *Arkiv. Kemi Mineral Geol.* 10B, No. 7, 1-6(1929); cf. C. A. 23, 2728, 3395.—In the oxidation of phenolphthalein to phenolphthalcin by means of  $H_2O_2$ ,  $CuSO_4$  was found to have a catalytic action similar to that of catalase of blood, tissues and other biol. materials. The trace of Cu found in most tissues may explain the catalase activity of the latter. The Cu is believed to be in the form of the anion,  $HOCuO$ . J. J. W.

Biochemistry of S (SULLIVAN, HESS) 10. The bile acids (SCHENCK, KIRCHOF) 10. Effect of radiation upon chemical and biochemical reactions (GERLACH) 3.

## B—METHODS AND APPARATUS

STANLEY R. BENEDICT

**An automatic drop recorder.** M. S. BISKIND AND MORRIS DAN. *Proc. Soc. Exptl. Biol. Med.* 26, 52-5(1928).—A description is given of an app. designed for perfusion and excretion expts. where a continuous record of outflow is desired. C. V. B.

**A method for determination of lipin phosphorus.** FRANCES KRASNOW AND A. S. ROSEN. *Proc. Soc. Exptl. Biol. Med.* 26, 67-8(1928).—A detailed description of a satisfactory technic is given. The method is applicable to blood and other biol. fluids.

C. V. BAILEY  
**A method for determination of volatile fatty acids in stools.** W. H. OLMSTED AND WALTER WHITAKER. *Proc. Soc. Exptl. Biol. Med.* 26, 108-9(1928).—Collect stools in an equal vol. of 10% NaOH soln.; neutralize 100 g. of the alk. mixt. with strong  $H_2SO_4$  and add 175-200 cc. of a 10%  $HgCl_2$  soln. Add solid  $Ca(OH)_2$  until the soln. is strongly alk. to litmus. Make up the vol. to 500 cc. and centrifuge. Acidify two 100-cc. portions to litmus with  $H_2SO_4$ . Ppt. excess Hg with  $H_2S$  and remove the latter by an air current. Filter, add 70 g.  $MgSO_4$  and 2 cc. of 50% soln. of  $H_2SO_4$ . Pass steam through the mixt. at such a rate that 10-15 min. is required to collect each 100-cc. fraction of distillate. Collect 6 fractions. Keep the vol. of the salt soln. const. The filtrates are almost free from  $N_2$  and from higher insol. fatty acids and sugar. The principal volatile fatty acids in the stools are acetic and butyric. C. V. BAILEY

**The physiological salt- and Locke-Ringer solutions.** M. E. BERGOLTZ. *Farm Zhur.* 1928, 444-8.—A discussion of the functions of the different constituents of these solns. and certain precautions to be taken in prepg. them. E. BIELOUSS

**A new apparatus for the clinical measurement of the respiratory quotient.** RENÉ WOLFF. *Compt. rend. soc. biol.* 101, 660-2(1929).—Benedict's basal metabolism app. is modified so as to measure the respiratory quotient. **Experimental results.** *Ibid.* 731-3.—The av. of 6 expts. for  $CO_2/O_2$  of alc. was 0.679 (0.658-0.699). The mean error of respiratory quotients of 6 patients varied from 0.619 to 1.7 with one case at 4.8

B. C. BRUNSTETTER

**A new colorimetric urea method with 0.1 cc. of blood.** SHUN-ICHI YOSHIMATSU *Tôhoku J. Exptl. Med.* 13, 1-5(1929).—Blood urea is pptd. by xanthhydrol, dissolved in  $H_2SO_4$ , digested with  $H_2O_2$ , and treated with Folin's phenol reagent. B. C. B.

**The occurrence of methylguanidine in the animal organism.** III. The use of benzenesulfonyl chloride for the separation of methylguanidine. I. A. SMOKODINTSEV AND A. N. ADOVA. *Z. physiol. Chem.* 182, 259-64(1929); cf. *C. A.* 23, 2451.—The quant. isolation of methylguanidine from tissue exts. is complicated by the presence of creatinine, which may serve as a source of this substance. A reagent which would ppt. methylguanidine and leave creatinine in soln. is highly desirable. The  $PhSO_2$  deriv. of methylguanidine has been described by Ackermann (*Ibid.* 48, 382) and is stated to be sol. in 2500 parts of  $H_2O$  at room temp., while creatinine forms no insol. deriv. Attempts were therefore made to sep. a mixt. by treatment with  $PhSO_2Cl$  and NaOH. The max. yield of benzenesulfonylmethylguanidine, however, from the pure base was only 31.4%, and from a mixt. contg. creatinine it was only 10%. As a reagent for methylguanidine,  $PhSO_2Cl$  is unsatisfactory. A. W. DOX

**Alkalimetric microchemical determination of amino acids and peptides.** W. GRASSMANN AND W. HEYDE. *Z. physiol. Chem.* 183, 32-8(1929).—The method is based on the Willstätter and Waldschmidt-Leitz principle, solns. of usual concn. being used but in special micro-app. Amino acids may thus be titrated in 0.004 millimol. quantities, e. g., 0.3 mg. glycine, with the same relative accuracy as in the macro-titration, the error being less than  $\approx 1\%$ . The app. required are (1) 1 cc. volumetric flasks of the usual design with ground-glass stoppers, (2) capillary pipets of 0.5, 0.2 and 0.1 cc. capacity graduated in 0.001 cc., (3) 5, 10 and 15 cc. Erlenmeyer flasks, and (4) a 2 cc. micro-buret graduated in 0.01 cc. The tip of the pipet below the graduations should be sufficiently long and slender to reach easily to the bottom of the flask. The outside should be wiped off each time with filter paper and the liquid delivered slowly. With a fine tip the buret will deliver alk. KOH (0.01 N in 90% EtOH) in drops of about 0.005 cc. Procedure: To the soln. to be titrated (e. g., 0.2 cc.) add 2 drops of 0.1% alc. thymolphthalein, and alkali from the buret until a distinct blue color appears. From a pipet add 9 vols. (e. g., 1.8 cc.) abs. EtOH, which discharges the blue color, and titrate to the end point. The final color should correspond to that of a 1/400 M soln. of  $CuCl_2$  in excess  $NH_4OH$ . A blank titration performed in the same way is then deducted. Titration of 5 amino acids and 4 polypeptides gave values in close agreement with the theory. The method was tested also in digestion expts. where

*dl*-leucylglycylglycine was hydrolyzed by yeast polypeptidase, gelatin by papain-HCN, and *dl*-leucylglycine by yeast dipeptidase. A. W. DOX

**Testing of hypodermic needles.** G. BATTÀ. *J. pharm. Belg.* 10, 927-30(1928).—The 3 principal causes of corrosion of needles are (1) action of the medicament, (2) continuous action of moist air and (3) the action of the metal of the mandrel, which can form a couple with the metal needle in the presence of ionizable medicaments. To det. Cr in the needles dissolve 100 mg. of needles in 0.2 N H<sub>2</sub>SO<sub>4</sub>, add a few drops of fuming HNO<sub>3</sub>, followed by 25 cc. of KMnO<sub>4</sub> soln. (2.5%), boil 15 min. and cool. Add 50 cc. of ammonia, boil 15 min. or until the KMnO<sub>4</sub> is decompd., cool, add 15 cc. concd. H<sub>2</sub>SO<sub>4</sub>, boil 10 min., and det. the chromate by reduction with Mohr's salt and KMnO<sub>4</sub>. Tests were carried out on needles contg. various percentages of Cr and of pure Ni. Corrosion was detd. as loss in wt. of the needles in the following media: 10% HNO<sub>3</sub>, 10% AcOH, and 10% NaCl after immersion for 2 hrs. at 20°. The needles contg. above 10% Cr were unaffected. Ni needles lost wt. in HNO<sub>3</sub>, were blackened by AcOH, and were unaffected by the salt. In the test to det. the effect of electrolytic action, the needles were partly immersed in a 5% NaCl soln. for 2 hrs., and then exposed for 50 hrs. to moist air. By this treatment Ni needles tarnished while steel was only slightly affected. In the case of the mandrels, Ni and nicked brass were resistant while steel became rusted in 30 min. of contact. Needles high in Cr content resisted much better than their mandrels. In moist air for 60 hrs. at 50° only the steel mandrels showed signs of rust. B. proposes that hypodermic needles be made of steel contg. a min. of 12-13% of Cr, and that the mandrels be plated with Ni, Cu or other suitable non-corroding metal. Steel mandrels should be entirely discarded. A. G. DUMÉZ

**Colorimetric estimation of minute quantities of sugar in the urine.** C. STRICH. *Pharm. Zentralhalle* 70, 437(1929).—The reagents required are: (a) 1% glucose soln. (exactly standardized), (b) Fehling soln., (c) K<sub>4</sub>Fe(CN)<sub>6</sub> soln. (1:20), and (d) NH<sub>4</sub>OH. Heat 5 cc. each of a and b in a Dahlen pressure water pot about 1 hour to complete pptn. in a centrifuge glass. After centrifugation, decant the supernatant liquid, wash twice, dissolve the residual Cu<sub>2</sub>O in about 3 cc. pure HNO<sub>3</sub>, dil. to 100 cc., then add 1 to 2 cc. of the resulting soln. to 100 cc. for colorimetric examn. with c (1 cc. = 0.1 mg. sugar) and d (10 cc. = 1 mg. sugar). By means of 3 to 10 cc. of the above Cu nitrate soln. the required color scale is obtained for comparison. For measuring the sugar content of urine a qual. test suffices for detg. the amt. of control soln. in comparing the intensity of color tone. W. O. E.

**Ultra-filtration methods and their application in bacteriologic and pathologic studies.** W. J. ELFORD. *Brit. J. Exptl. Path.* 10, 126-41(1929); cf. *C. A.* 22, 2095.—A simple and convenient method for prepg. impregnated AcOH collodion membranes with uniformity of thickness throughout. The complete concn. range is described. Also a suitable technic for prepg. such membranes in sterile condition by use of an ultra-violet light chamber is outlined. Evidence that ultra-filtration methods should prove of positive value in filterable virus studies is definitely established. However, intelligent cognizance of detg. factors in surface phenomena is imperative since the conception of filtration as consisting simply of a sifting process with relative pore size the sole controlling factor is wholly inadequate when dealing with truly colloidal and sub-colloidal systems. HARRIET F. HOLMES

**Hematoporphyrin test in the diagnosis of occult blood.** M. AHMANN AND A. KALLNER. *Arch. Verdauungs-Krankh.* 45, 169-72(1929).—It was not possible regularly to demonstrate hematoporphyrin in the stools. In some cases as many as 4 days elapsed between the disappearance of negative benzidine and pyramidone reaction and the appearance of hematoporphyrin. FRANCES KRASNOW

**The hydrogen-ion concentration of the feces and a simple method for its determination.** A. TILGER. *Arch. Verdauungs-Krankh.* 45, 221-4(1929).—Variations obtained ranged from 6.0 to 7.7. Boiled neutral water (5 cc.) was added to 7 tubes. Cresol red, naphtholphthalein, phenol red, bromothymol blue, neutral red, bromocresol purple and methyl red (4 drops), resp., were added to these tubes. Three to 4 drops of the material to be tested was added and the color matched with charts. FRANCES KRASNOW

**The occurrence and behavior of methemoglobin in the cadaver.** W. LAVES. *Deut. Z. ges. gericht. Med.* 12, 549-75(1928).—There may be formation of methemoglobin during the course of putrefaction. With careful spectrometric examn. sulfhemoglobin may be differentiated from alkali and acid methemoglobin. The post-mortem induction of methemoglobin begins in the vessels of the abdomen, continues in the heart blood and only later in the peripheral blood. Nitrite poisoning is recognizable through a gradual change of the methemoglobin into the very stable NO-hemoglobin. F. K.

**The determination of carbon monoxide in blood.** W. M. M. PILAAR. *J. Biol. Chem.* **83**, 43-50(1929).—See *C. A.* **22**, 4139.

**Gasometric determination of fermentable sugar in blood and urine.** A. P. LOTHROP, D. D. VAN SLYKE AND JAMES A. HAWKINS. *J. Biol. Chem.* **83**, 51-70(1929); cf. *C. A.* **23**, 404.—Procedures are described for applying the gasometric ferricyanide reduction method to detn. of fermentable sugar in blood and urine. Fermentable sugar is measured by the decrease in reducing material caused by brief contact with yeast under conditions producing complete removal of glucose. The usual normal urine contains about  $0.15 \pm 0.10\%$  of total reducing substances, of which on the av. only about  $1/10$  is fermentable. Only 3 urines out of 27 showed more than  $0.023\%$  of fermentable sugar. The normal fermentable sugar values are somewhat higher than Eagle's (*C. A.* **21**, 1296), which were below  $0.01\%$ , but confirm him in showing that only a relatively slight proportion of the reducing material usually encountered in normal urine can be glucose. The ingestion of 1 g. of glucose per kg. by 3 normal men did not in any of them increase significantly the concn. or output rate of fermentable sugar in the urine, this result again confirming Eagle. Manometric measurement of the  $\text{CO}_2$  formed by yeast indicated in normal urine fermentable sugar contents averaging  $0.03\%$  higher than those obtained from the decrease in reducing power. The extra  $\text{CO}_2$  is attributable to non-glucose urine constituents, of which amino acids and  $\alpha$ -keto acids have previously been shown to yield  $\text{CO}_2$  under influence of yeast carboxylase. In glucosuric urines the amt. of extra  $\text{CO}_2$  formed by yeast from non-glucose substances is relatively unimportant, and in such urines results by the  $\text{CO}_2$  method do not deviate significantly from those by the fermentation-reduction method.

**Tyrosine and tryptophan determination in one-tenth gram of protein.** OTTO FOLIN AND A. D. MARENZI. *J. Biol. Chem.* **83**, 89-102(1929).—The colorimetric methods for the detn. of tyrosine and tryptophan of Folin and Ciocalteu (*C. A.* **21**, 3210) have been modified so that accurate detns. can be made on 100 mg. of material

**An improved colorimetric method for the determination of cystine in proteins.** OTTO FOLIN AND A. D. MARENZI. *J. Biol. Chem.* **83**, 103-8(1929).—Refinements of the Folin-Looney method for the detn. of cystine have been made which render the method more accurate. A uric acid reagent free from phenol reagent is used (cf. following abstr.) and the amt. of  $\text{Na}_2\text{SO}_3$  has been so reduced that the blank occasioned by it becomes quite negligible. A better range of true proportionality between colors produced from different amts. of cystine is obtained; 0.5 mg. of cystine can be accurately detd. with a 1 mg. standard. The cystine contents of proteins detd. by the revised method are as follows: casein 0.30, gliadin 2.19, edestin 1.35, zein 1.03, crystalline egg albumin 1.22, recrystd., serum albumin  $6.02\%$  (all corr. for moisture content). In all cases except the gliadin the results are higher than those obtained by the Folin-Looney method. The value for casein is the highest that has been reported for that substance.

**The preparation of uric acid reagent completely free from phenol reagent.** OTTO FOLIN AND A. D. MARENZI. *J. Biol. Chem.* **83**, 109-13(1929).—The new reagent is far superior to the old not only for cystine but also for uric acid detns.; it is very active, yet possesses the highest obtainable degree of specificity and so gives the min. of blanks, with sulfite, cyanide, etc., and does not give a trace of color with tyrosine. In addition it shows less tendency to give disturbing ppts. In the prepn. of the reagent most of the uncombined molybdate which remains when just the right amt. of  $\text{H}_3\text{PO}_4$  is added to a  $\text{Na}_2\text{WO}_4$  soln. is pptd. by  $\text{H}_2\text{S}$  and the portion which is converted into sol. sulfomolybdates is removed by extn. with alc. It is possible to convert 100 g. of  $\text{Na}_2\text{WO}_4$  into 1 l. of uric acid reagent completely free from phenol reagent in 2 hrs. by the method described.

**An improved form of Folin's microchemical method for blood sugar determinations.** OTTO FOLIN AND HAQVIN MALMROS. *J. Biol. Chem.* **83**, 115-20(1929); cf. *C. A.* **23**, 2198.—The method has been so revised that with 1 standard and 1 detn. a range between 25 and 400 mg. % can be covered and approx. values can be obtained of blood sugars as high as 700 or 800 mg. %. The problem involved was how to measure Prussian blue in the presence of a large surplus of yellow  $\text{K}_3\text{Fe}(\text{CN})_6$  and it was found that the disturbing effects could be removed by the use of a light screen of filter paper stained a deep yellow with picric acid. The method thus becomes rather more photometric than colorimetric for the blue color is mostly replaced by light absorption and the end point in the colorimeter adjustment is more or less like what one observes in a polariscope and is easier to make than the usual color comparisons. The original range was from 50 to 200 mg. % so that the method could not be used for diabetic bloods. It has been

found that solns. made with gum ghatti instead of gum arabic keep practically indefinitely.

**A new plethysmograph and the actions of various drugs examined with it.** S. SUGIYAMA AND T. FURUKAWA. *Acta Schol. Med. Univ. Imp. Kioto* 11, 591-7(1929).—The accuracy of the ordinary plethysmograph for measuring vol. changes in limbs has been questioned; the authors have improved the plethysmograph so that its record is reliable. A rubber cuff (14 × 40 cm.) is connected to a glass T-piece; one open end of the T-piece connects to a funnel which is used to fill the rubber cuff with water. The other end is connected to an irrigator of glass (300 cc. content) which is provided with a glass stopcock. A glass ampoule (100 cc. capacity) contg. lead shot like a sp. gr. spindle floats in the fluid in the irrigator vessel and operates a lever as it rises or falls when the fluid changes its level in the vessel. The cuff is placed about the thigh of the patient and is then covered with a bandage to prevent expansion of its periphery. Water at 33° is poured through the funnel, fills the rubber cuff, pressing it close to the thigh and fills the irrigator vessel. The funnel is then clamped off and 15-30 min. is allowed for the level in the irrigator vessel to become constant. After drugs are given if there is a dilation of blood vessels water is forced from the cuff into the irrigator vessel—as the level rises the float ascends and pushes the writing lever up—a record is made on a drum. The results obtained with this plethysmograph are: (1) Adrenaline-HCl, Hypotonal, camphor and whisky increased the vol. of the blood vessels of the thigh. (2) Digalen, digifolin, caffeine, sodium benzoate, papaverine-HCl and  $\text{CaCl}_2$  decreased the vol. (3) Strophanthin, highly concd. grape sugar soln. and narcocon produced no change.

G. H. W. LUCAS

**The determination of the carbon dioxide content of the mixed venous blood.** II. Carbon dioxide equilibria between mixed venous blood and rebreathed air. M. C. G. ISRAELS AND F. W. LAMB. *J. Physiol.* 67, 315-24(1929); cf. *C. A.* 23, 3943.—The following details of technic are proposed for the detn. of the  $\text{CO}_2$  tension of the oxygenated venous blood: (1) The rebreathing bag should be filled with 4000 cc. of a mixture of 93.5%  $\text{O}_2$  and 6.5%  $\text{CO}_2$ . (2) Samples should be taken from the last of the air expired into the rebreathing bag from a deep expiration at the end of a rebreathing period. (3) The subject should respire to and from the bag at a slow rate, best suited to himself. (4) The length of the rebreathing period should be from 10 to 12 sec. in the normal resting subject. Under the conditions of exercise or disease the proper rebreathing time must be detd. for each subject.

J. F. LYMAN

**Direct determination of potassium and sodium in plants.** GABRIEL BERTRAND. *Ann. sci. agron.* 46 1-8(1929).—The plant material contained in a Pt, quartz or fused silica capsule (but not porcelain) is carbonized by heating in a furnace to faint redness in order to avoid fusing the ash or volatilizing the K and Na salts. When most of the carbon has disappeared the capsule is allowed to cool and its contents are extd. several times with hot  $\text{H}_2\text{O}$ . After being transferred to a filter, the filter and residue is dried, re-ignited and the extn. repeated. The combined filtrate is divided into 2 portions for separately detg. K and Na. To det. K, acidulate 20 cc. of soln. with HCl, ppt.  $\text{H}_2\text{SO}_4$  with  $\text{BaCl}_2$  in slight excess, filter, concentrate filtrate and washings to 20 cc., add 2 cc. concd.  $\text{HClO}_4$ , evap. almost to dryness, add 1 cc.  $\text{HClO}_4$ , dil. to 15 cc. with  $\text{H}_2\text{O}$  and again evap. to the 1st appearance of white fumes. Cool, add 20 cc. of 96% alc. contg. 0.2%  $\text{HClO}_4$ , let stand a short time, and decant the supernatant liquid through a tared Gooch crucible; repeat the operation 2-3 times. Free the  $\text{KClO}_4$  remaining in the capsule from foreign salts by recrystn. and dry to const. wt. at 125-30°. For the detn. of Na 2 reagents are required: (A) 100 g.  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$  plus 60 g.  $\text{CH}_3\text{COOH}$ , dild. to 1 l. and (B) 333 g.  $\text{Mg}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 4\text{H}_2\text{O}$  plus 60 g.  $\text{CH}_3\text{COOH}$ , dild. to 1 l. A is used for removing phosphates. Equal quantities of A and B are mixed, allowed to stand, several hrs. and any ppt. formed is filtered off. This forms the reagent for pptg. the Na. To 20 cc. of unknown soln. in a centrifuge tube add 5 cc. soln. A, centrifuge and filter; repeat a 2nd time, using 10 cc. of soln. A. Add 60 cc. of the pptg. reagent and after a short time test a few cc. of supernatant liquid for completeness of pptn. Let stand several hrs., filter on a tared Gooch crucible, wash several times with 10-cc. portions of the reagent, followed by 15-30 cc. 95% alc. and dry to const. wt. at 110°. Factor 0.0165.

K. S. MARKLEY

**The mercurimetric method for titrating alkaloids in biological material.** Studies on the curve of elimination of ethylstrychnine. GIUSEPPE GRAZIANI. *Biochim. terap. sper.* 16, 160-6(1929).—Ethylstrychnine was administered in 2 cg. daily doses to a rabbit, the urine collected, and the alkaloid detd. by the Votocek-Kasperek method. This method was not found adapted for studying the curve of elimination of the drug. The cause is due to insufficient concn. of the alkaloid in the urine. The alkaloid does

not reach the limits of concn. (0.01 to 0.03 g.) given by the authors in order to get satisfactory results. PETER MASUCCI

**Peroxidase reactions and new reagents.** A. CASOLARI. *Biochim. terap. sper.* 16, 167-74(1929).—Toluidine blue in the presence of fresh milk and HCHO acts as a H acceptor similar to methylene blue (Schardinger's reaction). Other reagents which reveal dehydrogenation and form dyes belonging to the rosaniline group are: (1) the leucobase of acid green (the Na salt of the sulfonic deriv. of diethyldibenzzildiaminotriphenylcarbinol); (2) dimethylaniline 5 drops, glacial AcOH 10 drops, H<sub>2</sub>O 10 cc.; (3) aniline 0.093 g., *p*-toluidine 0.053 g., H<sub>2</sub>O 10 drops, AcOH 10% 5 drops; (4) aniline 0.093 g., *p*-toluidine 0.017 g., *o*-toluidine 0.017 g., AcOH 10% 5 drops + 10 cc H<sub>2</sub>O. These reagents are sensitive in detecting blood, raw milk, the rancidity of fats and the presence of peroxidases in ethyl ether. PETER MASUCCI

**The determination of the coagulation of blood.** DAVID BARILARI AND D. FOSSATI. *Semana méd.* (Buenos Aires) 35, 963-9(1928).—A survey and description of the methods are given. A. E. MEYER

**The determination of bismuth in humors and tissues.** ORESTE CALCAGNO. *Semana méd.* (Buenos Aires) 35, 1397-1412(1929).—The different ways of elimination of Bi from the organism are discussed. The analytical methods of Mueller, Christiansen, Fournau, Dezani, *et al.*, are described and criticized. C. employs the method of Fresenius-Babo for the destruction of the org. matter. The acid soln. is pptd. with H<sub>2</sub>S, washed first with a soln. of H<sub>2</sub>S in H<sub>2</sub>O, later with H<sub>2</sub>O, then with EtOH. After the sepn. of As with (NH<sub>4</sub>)<sub>2</sub>S the Bi is dissolved in HNO<sub>3</sub> while the HgS can be filtered off. A usual As detn. is described. The Bi soln. is used for detn. according to Leger, or Aubry or Ganassi. These methods are completely discussed. A. E. MEYER

**New type of respiration chamber.** T. J. MANEY, P. L. HARDING AND H. H. PLACGE. *Science* 70, 44(1929).—A study was made of the respiratory activity of fruit held under various conditions of maturity, humidity and temp. Suitable air-tight chambers of low cost for carrying out the expt. were made from 5-gal. pickle jars. L. B. M.

**Calorimetric microchemical determination of non-protein nitrogen in blood and serum.** B. GROÅK. *Biochem. Z.* 209, 148-53(1929).—Place in a centrifuge tube 4 cc H<sub>2</sub>O. Then measure out 0.1 cc. blood or serum with a capillary pipet and thoroughly mix with the water. Then add 0.9 cc. 30% CCl<sub>3</sub>COOH and centrifuge after 10 min. The detn. is carried out on 1 cc. of the clear liquid, which should give no turbidity when tested with sulfosalicylic acid. Measure this into a medium-sized test tube and mix with 3 drops H<sub>2</sub>SO<sub>4</sub> and 0.5 cc. H<sub>2</sub>O<sub>2</sub>, and finally add a trace of K<sub>2</sub>SO<sub>4</sub>. Heat the tube over an asbestos gauze until the contents are clear. With 2 portions of 5 cc. H<sub>2</sub>O transfer this to another tube and mix thoroughly with 0.2 cc. 40% NaOH and 1 drop of gum arabic. This gum arabic mucilage must be freed from every trace of NH<sub>3</sub> by dialyzing 12-24 hrs. against running water. The concn. should be so adjusted that 1 drop added to 10 cc. H<sub>2</sub>O will not manifest the least opalescence in diffuse light. Now follow the gum arabic by 0.2 cc. Nessler reagent, and match the colors after 15-20 min. S. M.

**The staining of the lipid granules of leucocytes, including considerations of the refractoriness of lipoids toward the oxidase staining reaction.** J. GOLDMANN. *Centr. Bakt. Parasitenk.*, I Abt., 112, 445-6(1929).—The leucocytic granules which stain with fat stains as Sudan III are morphologically identical with those demonstrated by the oxidase or peroxidase reaction. A different degree of resistance toward the oxidase reaction characterizes the granules of the various leucocytes. The granules of eosinophiles are most resistant and those of monocytes least, with neutrophils intermediate. JOHN T. MYERS

**The vital staining substance of erythrocytes.** RAPHAEL GAVRILOV. *Folia Haematol.*, I Abt., 38, 216-32(1929).—The lipid theory of the mechanism of vital staining fails to accord with many facts. Fat solvents do not remove the basophilic staining properties, even when the cells are left apparently fat-free. It is probable that the vital staining substance is a protein which may be combined with a lipid. The staining mechanism of polychromasia and vital staining are identical. The ground substance in an immature erythrocyte is in a state of dispersion. Various fixing and staining methods can by different types of coagulation of these colloidal particles produce various pictures from polychromasia to vital structure. Air-drying of a film with later fixation coagulates with fine particles. Application of a basic stain to an unfixed film produces some chem. reaction with the pptn. and coagulation of coarse particles. The more slowly water is removed from the cell the more complete and definite is the coagulation. Granulations of varying size can often be seen in the same prepn. Staining depends on chem. reaction between dye and cell substance. A low H-ion concn. is favorable. This influence of  $\phi_{\text{H}}$  speaks against the lipid-dye soly. theory of supravital

staining. Presence of vital staining material is the surest sign of a young erythrocyte.

**Heme and tissue iron.** M. L. ANSON AND A. E. MIRSKY. JOHN T. MYERS. *J. Gen. Physiol.* 12, 401-5(1929).—A method is described for estg. the heme in yeast and the wing muscles of bees. The density of the  $\alpha$  band of hemochromogen in the complete tissue-pyridine mixt. is compared with the density of the  $\alpha$  band of a series of known solns. of pyridine-hemochromogen. Certain difficulties of the method are discussed. About 40% of the total iron of baker's yeast and the wing muscles of the bee is the form of heme.

**Modification of the Northrop-Kunitz microcataphoresis cell.** C. H. RICHARDSON. HAROLD A. ABRAMSON. *J. Gen. Physiol.* 12, 469-72(1929).—The cell differs from the Northrop-Kunitz cell (C. A. 19, 2966) as follows: (1) Electrode vessels are fused to the cell; (2)  $\text{CuSO}_4$  electrodes are used in electrolyte-free agar or in salt solns. contg. agar depending upon the type of expt.; (3) the drop in potential is calcd. from Ohm's law to avoid errors due to accidental resistances.

**The salicylates.** VII. The alleged inefficiency of the phosphoric acid-distillation method of estimating salicylic and salicyluric acids. CHARLES C. JOHNSON. *J. Pharmacol.* 34, 437-44(1928).—A comparison was made of recovery of salicyl from various solns. by the Thoburn-Hanzlik procedure, and by Holmes' modification of it. Recovery of salicylic acid from aqueous solns. of sodium salicylate was, by the Thoburn-Hanzlik method, 89-98.3%; by Holmes' method 55.6-85.1%. Recovery of salicyl from the urines of human subjects taking  $\text{NH}_4$  or Na salicylate was 5-25% higher by the Thoburn-Hanzlik method. Recovery of synthetic salicyluric acid added to urine, and to water, was by the Thoburn-Hanzlik method 81-97.3%; by Holmes' method 0-52%. The results refute Holmes' criticism of the Thoburn-Hanzlik method, and indicate that Holmes' modification of it is unsatisfactory.

**Quantitative biochemical analysis of allantoin in the presence of urea.** R. FOSSE, A. BRUNEL AND P. DE GRAEVE. *Compt. rend.* 188, 1418-21(1929); cf. C. A. 23, 3875.—The detn. of allantoin in pure solns. means detn. of the urea produced by the successive action of alkali and acid; this method is not applicable in presence of urea or its derivs. If, however, the alkali is replaced by *Soja hispida*, the allantoinase transforms the allantoin into allantoic acid. Heat a soln. contg. 1 g. or less allantoin per l. on the water bath for 5-6 hrs. at 60° or for 10 hrs. at 40°, in presence of "ammonium subcarbonate" and  $\text{CHCl}_3$ . Neutralize 5 cc. of the filtered liquid in presence of methyl orange, add *N* HCl to make the titer 0.05 *N*, heat for 30 min. at 60°, make alk. with "soda" and clarify with "acetic iodo-mercurate." Filter and wash into a graduated test tube, add to the liquid (about 10 cc.) twice its vol. of  $\text{AcOH}$  and  $\frac{1}{20}$  of the total vol. of methylxanthhydrol, let stand 4 hrs. The ratio of allantoin to xanthylurea = 0.188. The method and its accuracy, demonstrated by tables, are not changed if urea is used instead of ammonium carbonate.

**Application of the biochemical determination of allantoin to urine.** R. FOSSE, A. BRUNEL AND P. DE GRAEVE. *Compt. rend.* 188, 1632-4(1929); cf. preceding abstract.—Glyoxylic acid and urea are formed in the soy-bean fermentation and subsequent acid hydrolysis of uric acid just as in the case of allantoin. Therefore, any uric acid present in the fluid to be tested for allantoin has to be eliminated before the fermentation. This is accomplished by means of the reagent of Denigès (acid Hg sulfate), which ppts. uric acid in concns. upward from 1:100,000 (Denigès, *Chimie analytique*, 5th ed., pp. 203 and 53 (1920)). The results of allantoin detns. on a number of animal urines are given in a table.

**Device for determining cholesterol in blood.** SAMUEL L. LEIBOFF. U. S. 1,722,435, July 30. Structural features.

**Clarifying blood.** EMMET P. SHEERAN (to Fostoria Serum Co.). U. S. 1,723,212, Aug. 6. Serum is sepd. from the heavy portion of the blood with a slight residue of such heavy portion remaining in the serum and the serum is then passed through a rotating bowl for further sepn. and clarification. An app. is described.

## D—BOTANY

THOMAS G. PHILLIPS

Some reactions of seedlings to weak concentrations of hydrochloric acid and calcium. JOHN R. SKEEN. *Soil Sci.* 26, 471-8(1928).—*Agrostis alba* in balanced nutrient solns. showed a growth independent of  $\text{pH}$  within the limits 3.7-6.0. *Lupinus albus* responded markedly to traces of Ca and derived no additional benefit when the concn. exceeded 3 p. p. m. *Phaseolus*, on the other hand, did not respond significantly

to concns. of less than 5.0 p. p. m. of the same element, and the benefit was greater with higher concns. *Phaseolus* did not survive a  $pH$  with HCl lower than 4.5, whereas a  $pH$  of 4.1 had little effect on lupins. Distd.  $H_2O$  showed a greater toxicity to *Phaseolus* than to *Lupinus albus*. It is thought that some soils are toxic to *Phaseolus*, not because of the toxicity of the H ion but because of the absence of ions in the soils.

M. S. ANDERSON

**The factors in the process of oil formation in plants.** SERGIUS IVANOV. (*Osterr. Chem.-Ztg.* 32, 89-90(1929); cf. *C. A.* 23, 2313.—A report of a lecture in which the results of I.'s 25 years' investigation in this field are summarized. The process of oil formation in plants is similar within a given genus. The oils of the species in a given genus are similar in chem. compn. Seeds from plants cultivated in northern Europe or at a high altitude contain oils whose I no. and drying capacity are always higher than those of oils from the plants cultivated in southern Europe or at a low altitude. This climatic effect is believed to be due chiefly to the influence of temp. Climatic conditions have little or no effect on the I no. of the fats of non-drying oils.

B. C. BRUNSTETTER

**The phytosterol of stinging nettle.** L. ZECHMEISTER AND P. TUZSON. *Z. physiol. Chem.* 183, 74-7(1929).—An alc. ext. of dried, finely ground nettle leaves (*Urtica urens*) was used for the prepn. of xanthophyll by concn. and pptn. with petroleum ether. The mother liquor, after concn. and addn. of EtOH, yielded crystals of a sterol which was identified as sitosterol free from stigmasterol. The yield of pure substance was 6 g. from 28 kg. of dried plant. The unavoidable losses being taken into account, the sterol content is estimated at 0.04% on the dry basis.

A. W. DOX

**Apparatus for the determination of carbon dioxide in the respiration of apples.** P. L. HARDING, T. J. MANEY AND H. H. PLAGGE. *Science* 70, 125-6(1929).

E. H.

**Chlorotic diseases of fruit trees: Their causes and remedies.** I. DE V. MALHERBE. *Farming in S. Africa* 4, 49-50, 54(1929).—The relation of the phys. and chem. compn. of soils to chlorosis in fruit trees is discussed. Chlorosis may result from a deficiency of available Fe, N or Mg compds. in the soil, from the presence of excessive quantities of alkali salts, or from too much or too little moisture. In acid soils, too high concns. of Mn salts cause true chlorosis, while the chlorotic condition of trees growing on highly calcareous soils may often be remedied by applications of Mn salts. Chlorosis due to a deficiency of available N is best combated by application of nitrate fertilizers. Trees growing on moderately acid soils, or soils abundantly supplied with org. matter, do not suffer from chlorosis due to a deficiency of available Fe. K. D. J.

**Experiments with barley of the same stock but of varying nitrogen content.** ANON. *J. Dept. Agr. Ireland* 28, 183-4(1929).—A lower yield of barley was obtained from seed having a high N content than from seed of the same stock having a low N content, but there was no difference in the quality of the grain.

K. D. JACOB

**Chemical activity of plants in relation to climate.** S. L. IVANOV. *Zhur. Prikladnoi Khim.* 1, 299-315(1928); cf. *C. A.* 22, 4149.—Mild warm climate favors formation of satd. fatty acids and of unsatd. acids with one double bond. Cold climate favors formation of unsatd. acids with 2 and 3 double bonds. Temp. and light are of special importance in these processes. Careful study of this new branch of science (hulegeography) is urged.

V. KALICHEVSKY

**Variations of iodine in one of the Florideae.** F. CHEMIN. *Compt. rend.* 188, 1624-5(1929); cf. *C. A.* 22, 2965.—*Trilliella intricata* filaments gathered in March gave a test for I when dipped in acid. This combined I is concd. in a portion of the secretive cells, possibly as a result of the cellular activity of the assimilative cells. As growth slows up, the I test becomes weaker and disappears entirely in April.

AMY LEVESCONTE

**The action of Wood's rays during the germination and the first periods of growth of plants.** S. COLLA. *Boll. soc. ital. biol. sper.* 4, 298-301(1929).—Wheat, beans and lentils were studied. The formation of chlorophyll is due to the action of ultra-violet rays (3300-3900 A. U.) without the aid of the visible rays. It seems also that under the action of the ultra-violet rays the anthocyanin disappears.

PETER MASUCCI

**Chemical composition of apple juices as affected by climatic conditions.** JOSEPH S. CALDWELL. *J. Agr. Research* 36, 289-365(1928); cf. *C. A.* 22, 3000, 4182.—A 6-year study was made of the variations in compn. of the expressed juices from 216 varieties of apples grown near Wash., D. C., and of their relations to the annual variation in climatic conditions. The compn. of the crop of a given year, when the results are considered collectively, shows a definite relationship to the amt. and distribution of the climatic factors during the growing season of that year. These climatic factors exert an effect upon compn. which manifests itself as a modification in like direction and degree of the compn. of the fruit of a large number of varieties of widely diverse

character and degree of adaptation to locality. Variations in amts. of sunshine and temp. were most effective in detg. the compn. of the crop; variation in pptn. was the least effective. An increase or decrease in the amt. of sunshine and temp. over normal results in a corresponding change in sugar content. The climatic conditions conducive to the development of a high content of sugar and acid in apples are also conducive to the reduction to a low level of the content of astringent materials therein and *vice versa*. In consequence the acid-astringent-sugar ratio of a given variety will vary quite widely from year to year in a locality having a wide variation in seasonal conditions and will have relatively narrow variations in a region having a narrow range of variation in seasonal conditions.

W. H. ROSS

**Variations in potassium content of alfalfa due to stage of growth and soil type and the relationship of potassium and calcium in plants grown upon different soil types.** JOHN F. FONDER. *J. Am. Soc. Agron.* 21, 732-50(1929).—The stems and leaves and their juices from alfalfa plants grown upon different soil types were analyzed for K at a no. of growth stages. Variations in the K content at different hrs. of the day were noted as was also the relationship of K to the sp. gr. of the expressed juice of the plant parts. The distribution of K in the sap and in the woody tissue of the plants was detd. A consideration of the physiol. relationship between K and Ca was made. Soil type differences were responsible for marked variation in the K content of alfalfa stems and leaves and of their juice. The greatest amts. of K were present in the plants grown upon the light sandy soils; medium amts. were present in the plants obtained from the very heavy soils; and the smallest amts. were present in the plants from the sandy loam soils. The K content of the plants was not an exact function of soil texture. Greater amts. of K were present in alfalfa stems than in the leaves, while about equal amts. were present in the expressed juice of the 2 plant parts. As the growth period advanced there was a decided decrease in the % of K present in the stems and leaves and their juice. About equal amts. of K were present in the plants of the first and second crops and apparently the K content of the soil was not depleted at any time to the extent that it controlled the % of K contained in the plants. K was evidently not an important cation in detg. the sp. gr. of the expressed juice of alfalfa stems and leaves, an increase in the sp. gr. usually occurring in spite of a decrease in the concn. of K in the juice. The K present in the green material of the alfalfa stems and leaves existed largely in soln. in the plant sap, very little of it being held intimately in the woody tissue. About equal amts. of K were present in the woody tissue of the stems and leaves, although slightly more was deposited in the woody tissue of the leaves by the full-bloom stage. In the plants obtained from some soil types increasing amts. of K were deposited in the woody tissue, while in the plants from the other soil types a decrease occurred during the growth period. A physiol. balance between K and Ca appeared to exist in the alfalfa plants. An inverse correlation was established between these 2 elements in the plants obtained from the different soil types, an increased Ca content being found to be accompanied by a decreased K content, both at different stages of growth and in the different plant parts. K and Ca appeared to be interchangeable in the plants, although not necessarily alike functionally. The K content of the plants depended upon the Ca content, which in turn appeared to be dependent upon the available supply of this element in the soil, although the last cannot be definitely stated without further data. E. F. SNYDER

**Luxury consumption of potassium by plants and its significance.** R. P. BARTHOLOMEW and GEORGE JANSSEN. *J. Am. Soc. Agron.* 21, 751-65(1929).—Plants absorb considerable more K during the early periods of growth than is necessary for the normal processes of growth. This applied to alfalfa, Hubam clover, cowpeas, soy beans, oats, wheat, Sudan grass, corn, cotton and tomatoes. The K in the tomato is practically all water-sol. K can be translocated within the plant and re-utilized to prevent starvation when the supply of available K is insufficient to supply the needs of the growing regions. E. F. SNYDER

**Quantitative changes in the chloroplast pigments in the peel of bananas during ripening.** HARRY VON LOSSECKE. *J. Am. Chem. Soc.* 51, 2439-43(1929).—The pigments, chlorophyll ( $a + b$ ), xanthophylls and carotin were detd. in the peel of bananas. The data indicate that the chlorophyll content of the peel ranges from 102.9 to 51.7 mg. per kg. of fresh peel in the unripe fruit at discharge from the boat and decreases as the fruit ripens. Chlorophylls decrease as a straight-line function of time. The total yellow pigments (xanthophyll + carotin) remain approx. constant throughout the maturation of the fruit. The amt. of xanthophylls is always greater than the amt. of carotin, the range of the former being from about 5 to 7 mg. per kg. of fresh peel, while the range of the latter is from 1.5 to 3.5 mg. per kg. of fresh peel.

C. J. WEST

**Chemical composition of corn (*Zea mays*) seedlings. I. Isolation of xylan and cellulose from the cell walls.** KARL PAUL LINK. *J. Am. Chem. Soc.* **51**, 2506-16 (1929).—Corn seedlings grown at 12° and 24° to the stage where the coleoptile ruptures the leaf sheath contain 10-12% xylan and 16-18% cellulose. Of the xylan 85-90% can be extd. with 5% NaOH (xylan A) and the remainder with 10% NaOH (xylan B); in the pure state both xyans are sol. in hot H<sub>2</sub>O, are strongly levorotatory and can be quantitatively hydrolyzed to *d*-xylose. The cellulose is composed entirely of glucose residues and resembles the cellulose of cotton in its chem. reactions and also in its high mol. complexity. No sugars other than xylose and glucose have been detected in the hydrolysis products obtained from the cell wall constituents of the corn seedling. Temp. did not alter the qual. nature of the xylan and cellulose constituents laid down in the cell walls but alters slightly their quant. distribution. The original should be consulted for the details of exptl. procedure. **II. Isolation of a dextrin similar to the trihexosan obtained by the thermal depolymerization of potato starch.** *Ibid* 2516-22.—A dextrin has been isolated from the radicle and plumule of corn seedlings, which appears to be similar to the trihexosan obtained by the thermal depolymerization of potato starch. The dextrin comprises approx. 65% of the total dextrin content of the corn seedlings. Since the dextrin belongs to the starch dextrin series, it appears probable that it is a polysaccharide substance used in the respiratory process of the seedlings. C. J. W.

**Occurrence of ergosterol in phytosterols.** I. M. HEILBROD AND W. A. SEXTON. *Nature* **123**, 567 (1929).—In addition to the reduction of sitosterol to sitostanol, it may concurrently undergo oxidation to ergosterol. J. J. WILLAMAN

Plant pigments (KARRER, *et al.*) 10.

## E—NUTRITION

PHILIP B. HAWK

**Effect of infra-red radiation on growth of rachitic rat.** ETHEL M. L. CLAUSEN. *Proc. Soc. Exptl. Biol. Med.* **26**, 77-8 (1928).—A 10 min. daily exposure to near infra-red radiation (ranging from 720 to 1120 $\mu$ ) of an intensity 0.132 g. cal. min./sq. cm will produce in young rats fed upon a rickets-producing diet increased growth and prolongation of life for 4-6 weeks, without any effect upon the disease. There is an associated hypertrophy of the thyroid and of the parathyroid glands. C. V. BAILEY

**Influence of arsenic, ferrous sulfate and copper sulfate on rats furnished a vitamin-A-free diet with iron added.** F. F. CHIDESTER AND A. G. EATON. *Proc. Soc. Exptl. Biol. Med.* **26**, 141-2 (1928).—Two male rats were given Sherman vitamin A-free diet No. 380 to which was added 0.01 mg. Cu in the form of CuSO<sub>4</sub>, 0.5 mg. of Fe in the form of FeSO<sub>4</sub>, 0.379 mg. As in the form of Fowler's soln. and 0.01 mg. irradiated ergosterol. From an av. wt. of 42 g. they reached a max. wt. of 175 g. at the end of 9 weeks, after fluctuating around 170 g. for 2 weeks, a rapid decline resulted in death at the end of 13 weeks. Similar results were obtained with a group of 4 female rats. C. V. BAILEY

**Influence of wheat germ oil on fertility of rats fed fat-free rations.** AMY L. DANIELS AND DOROTHY P. JORDAN. *Proc. Soc. Exptl. Biol. Med.* **26**, 185-8 (1928).—The effectiveness of wheat germ oil as an antisterility agent is due to the presence of some substance (vitamin E) contained therein, and not to any retarding action which this may have on the oxidation of vitamin A. C. V. BAILEY

**Growth and reproduction of rats on vitamin-C-free diet.** ERNEST T'SO. *Proc. Soc. Exptl. Biol. Med.* **26**, 276-7 (1929).—The addn. of antiscorbutic vitamin had no growth-promoting effect when given to rats which for 2 generations or more had been reared on a vitamin-C-free diet. C. V. BAILEY

**The possible significance of *d*-xyloketose (urine pentose) in normal metabolism.** ISIDOR GREENWALD. *Proc. Soc. Exptl. Biol. Med.* **26**, 321-2 (1929).—*d*-Xyloketose *p*-bromophenylhydrazone, prepd. by a modification of the method of Levene and LaForge, 127-8°, decomposed 165°; in 1% soln. in alc.  $[\alpha]_D^{20} = 1.87^\circ$  shortly after prepn., and 2.43° after 24 hrs. For the free ketose, prepd. by reaction with BzH,  $[\alpha]_D^{20} = 34.8^\circ$ . The glucose equiv. of 1 g. of pentose calcd. from the *p*-bromophenylhydrazone was 1.25 g. by Sumner's method, 1.45 g. by the NaOH-picric-acetone method and 1.18 g. by the Na<sub>2</sub>CO<sub>3</sub>-picric method of Benedict and Osterberg. Ninety cc. of this soln. (equiv. to 3.05

g. pentose) in 5 injections at intervals of approx. 2 hrs. increased the sugar content of the urine of a dog about 6% of the amount injected. A few days later the dog received a similar series of injections of *l*-xylose; about 60% appeared in the urine. Another control expt. with glucose gave no increase in the excretion of sugar. *d*-Xyloketose can be further metabolized by the organism. C. V. BAILEY

**Influence of whole wheat upon hemoglobin regeneration in albino rats.** MARY S. ROSE, ELLA MCC. VAHLTRICH AND EMILY L. BLOOMFIELD. *Proc. Soc. Exptl. Biol. Med.* 26, 322-3(1929).—Young rats weaned at the age of 3 weeks from mothers on a uniform diet were made anemic by exclusive feeding of pasteurized milk. After 11 weeks the hemoglobin, as detd. by the Newcomer method with the Newcomer disk, showed values between 5.8 and 4.5 g. per 100 cc. of blood. One-half of the rats were then fed daily 6 g. of whole wheat contg. 0.2 mg. of Fe. The hemoglobin rapidly increased and in a few weeks values ranged from 15 to 19 g. per 100 cc. of blood. All the controls continued to decline. C. V. BAILEY

**Effect of an exclusive meat diet on chemical constituents of the blood.** CLARENCE W. LIEB AND EDWARD TOLSTOI. *Proc. Soc. Exptl. Biol. Med.* 26, 324-5(1929).—Two healthy men lived exclusively on meat for 11 months and remained in excellent health. There was no evidence of renal impairment. The chem. compn. of the blood showed a slight increase in uric acid and a temporary lipemia following the ingestion of unusual amts. of fat. C. V. BAILEY

**Effect of hydroquinone in vitamin A deficiency.** HOWARD H. BEARD, ELIZABETH POMIERNE AND REGINALD A. SHIPLEY. *Proc. Soc. Exptl. Biol. Med.* 26, 328-9(1929).—Rats were fed a diet free from vitamin A and each day were given by mouth 5 drops of a soln. of hydroquinone equiv. to 7 mg. of the phenol. Others were given the diet plus 0.1 g. of hydroquinone per 100 g. of food. The phenol had no effect in preventing loss of wt., ophthalmia and death. C. V. BAILEY

**Influence of epinephrine on blood-sugar utilization of functionally hepatectomized rats.** CARL F. CORI AND GERTY T. CORI. *Proc. Soc. Exptl. Biol. Med.* 26, 345-7(1929).—Rats that have fasted for 24 hrs. contain  $5.8 \pm 1.4$  mg. of liver glycogen per 100 g. rat. The tolerance limit for intravenously injected glucose is at a rate of 250 mg. per 100 g. rat per hr. When 0.03 mg. of epinephrine is injected subcutaneously and glucose supplied at a rate of only 100 mg. per 100 g. rat per hour, 75% of the injected glucose remains unutilized in the blood and body fluids. In functionally hepatectomized rats the sugar and lactic acid contents of the blood were higher after glucose plus epinephrine than after glucose alone. The results are attributed to the inhibiting action of epinephrine upon the utilization of glucose in the tissues. C. V. BAILEY

**Fundamental food requirements for growth of rat.** L. S. PALMER AND CORNELIA KENNEDY. *Proc. Soc. Exptl. Biol. Med.* 26, 427-30(1929).—Rats were fed diets contg. various amts. of fat without lettuce or liver supplements and the efficiency of the food utilization was studied. The results do not support the postulation of Evans and Burr of an essential growth vitamin F associated with fat. C. V. BAILEY

**Influence of superheating on antirachitic properties of irradiated foods.** AMY L. DANIELS AND DOROTHY JORDAN. *Proc. Soc. Exptl. Biol. Med.* 26, 453-5(1929).—A comparison was made over a period of 10 weeks of rats receiving a rachitic ration with rats receiving similar rations irradiated, and an irradiated ration subsequently autoclaved at 15 lb. for 6 hrs. Similar tests were made with the addn. to the diet of boiled milk and in other tests evapd. milk. Superheating, as in this expt., does not affect the antirachitic properties of food. C. V. BAILEY

**An attempt to secure "refection" in rats.** LAFAYETTE B. MENDEL AND HUBERT B. VICKERY. *Proc. Soc. Exptl. Biol. Med.* 26, 552-5(1929).—The authors failed to reproduce the "refection" reported by Fridericia, *et al.* (cf. *C. A.* 22, 1383). C. V. B.

**Effect of feeding whale oil on the depot fat of the white rat.** J. B. BROWN AND A. L. RAWLINS. *Proc. Soc. Exptl. Biol. Med.* 26, 704-5(1929).—Equil. between food fat and depot fat is established within 4-6 weeks on a given diet. The characteristic highly unsatd. fatty acids of whale oil are apparently deposited as such and when once stored are removed slowly; a considerable quantity remained in the depot fat 3 weeks after the resumption of the control diet. C. V. BAILEY

**Vitamin A as an anti-infective agent.** F. MELLANBY AND H. N. GREEN. *Brit. Med. J.* 1929, I, 984-6.—Treatment of 5 cases of puerperal septicemia with prepn. rich in vitamin A resulted in complete recoveries. Vitamin A raises the body resistance against infective microorganisms. J. B. BROWN

**The influence of diet on blood sugar regulation.** E. GEIGER AND HILDE KROFF. *Arch. exptl. Path. u. Pharmacol.* 139, 290-301(1929).—Alimentary blood sugar curves were much lower after feeding oats than after a green fodder diet. Such curves were

raised by the addn. of acid to the green fodder diet, but lowered by the addn. of alkali. The decreased sugar tolerance after a green fodder diet is not due to lack of glycogen in the liver. The increased sugar tolerance after an oats diet is decreased by the addn. of acid to the diet.

**The importance of inorganic compounds for animal nutrition.** A. SCHÜNBERT. *Mitt. deut. Landw.* 44, 336-42(1929).—A review, with special reference to German agricultural conditions.

**The occurrence of vitamin A in blood and blood serum of domestic animals, in cow milk, milk products and in some feeds.** BIRGER RÖSIÖ. *Z. physiol. Chem.* 182, 289-304(1929).—Detns. of vitamin A content were made with  $\text{CHCl}_3$  exts. of the materials examd., using the  $\text{SbCl}_3$  color reaction and the Lovibond tintometer. Blood serum from a no. of animals was examd. to det. whether quant. differences in reactivity to  $\text{SbCl}_3$  might be due to such factors as species, age, sex and pregnancy. On the basis of this reaction it appears that the blood of cattle contains more vitamin-A (or carotinoid) than that of horses, and that of pregnant more than that of non-pregnant females. From birth to old age there is a steady decrease in vitamin-A content except during periods of pregnancy. Cream from the milk of different breeds of cows was examd. in the same way. The best grades of milk gave the strongest reactions. Less reactive were certain feeds, e. g., turnips, beets, mangold and soy meal.

**Calcium and phosphorus metabolism in dairy cows. III. The adequate ration for high-producing cows and the effect of exercise on calcium, phosphorus and nitrogen balances.** WM. A. TURNER AND ARTHUR M. HARTMAN. *J. Nutrition* 1, 445-54(1929); cf. *C. A.* 20, 2694.—Two cows receiving a high quality, dry ration consisting of well-cured alfalfa hay, mangel beets and a good grain mixt. (Ca/P ratio 1.09-1.19), and yielding 27 and 22 kg. of milk daily, remained in prevailing neg. Ca and P balances throughout a 7 weeks' period. This occurred in the early part of the lactation period. During the last 3 weeks of the expt. the introduction daily of  $\frac{1}{2}$  hr. of exercise produced slight and probably insignificant effects on the Ca and P metabolism but a very marked effect on N metabolism. Without allowing for exercise, the animals received 5% more than their energy requirements calcd. on the basis of the Savage standard.

**The effect of heat on the antineuritic vitamin of milk.** AMY L. DANIELS, MATE L. GIDDINGS AND DOROTHY JORDAN. *J. Nutrition* 1, 455-66(1929).—The object was to test the vitamin B potency in dried (spray and roller), canned, boiled, and pasteurized (open and closed methods) milk, since all of these preps. are used in infant feeding. With the exception of the milk dried by the roller process, all the super-heated milks gave evidence of considerable destruction of vitamin B. The results with the open-method pasteurized milk also showed a slight loss of vitamin; this was much less, however, than in either evapd. or milk dried by the spray process. Milk pasteurized by the closed method gave no evidence of vitamin-B destruction. Milk heated quickly to the b. p. and slowly cooled was affected approx. to the same degree as open-tank pasteurized milk. If boiled quickly and rapidly cooled, milk loses little or none of its vitamin-B potency. Temp. and aeration are important factors in detg. the degree of destruction of vitamin B in milk.

**Chemical detection of vitamin C.** B. GLASSMANN AND A. POSDEW. *Z. Untersuch. Lebens.* 17, 191-200(1929).—A close relationship was found between color produced by the Bezssonow phosphomolybdotungstic acid reagent (*C. A.* 18, 2191, 3207) and the carbohydrate content of a no. of fruit juices contg. vitamin C. Tannins seriously interfere with the test. Juices contg. from 0.5 to 1.5 mg. of tannic acid in 10 cc. gave a color similar to that of the hydroquinone. Conclusion: Animal expts. are at present the only reliable means of detg. the antiscorbutic properties of foods.

**The vitamin C content of fresh and frozen milk.** WALTER SALECK. *Milchwirt. schaft. Forsch.* 6, 464-85(1928).—S. finds that it requires between 10 and 15% of body wt. of fresh milk to protect guinea pigs against scurvy but over 15% of the same milk after freezing.

**Vitamin D from sterols of mummified Egyptian brain.** HAROLD KING, OTTO ROSENHEIM AND ARTHUR WEBSTER. *Biochem. J.* 23, 166-7(1929).—The authors prepd. cholesterol esters from the brain of the mummy. The esters showed the blue color with  $\text{CCl}_4\text{CO}_2\text{H}$  said to be sp. for ergosterol (cf. Rosenheim, *C. A.* 23, 2733); they also gave a green color with Br soln. when dissolved in  $\text{CHCl}_3$ , a reaction said to be characteristic for ergosterol and not given by pure cholesterol (cf. Häussler and Branchli, *C. A.* 23, 2735). The absorption spectrum of ergosterol (280-290 $\mu$ ) was also obtained. Antirachitic action was obtained by irradiating these esters and feeding them to rats.

**Effect of excessive doses of irradiated ergosterol on the calcium and phosphorus**

content of the blood. LESLIE J. HARRIS AND CORBETT P. STEWART. *Biochem. J.* 23, 206-9(1929).—In the young rat, the administration of a complete synthetic diet (normal Ca-P ratio) contg. 0.1% of irradiated ergosterol was followed by a 50% increase of inorg. phosphate and a 25% increase of serum Ca. In adult rabbits on a normal mixed diet, the administration of 10 mg. *per diem* of irradiated ergosterol per animal gave rise to a 50% increase in the inorg. phosphate, but to no significant increase in Ca, although abnormal deposits of Ca had already appeared in the body. BENJAMIN HARROW

Hypervitaminosis and vitamin balance. II. The specificity of vitamin D in irradiated ergosterol poisoning. III. The pathology of hypervitaminosis D. LESLIE JULIUS HARRIS AND THOMAS MOORE. *Biochem. J.* 23, 261-73(1929); cf. *C. A.* 23, 1937.—Excessive vitamin D induces a condition of specific hypervitaminosis. "Radiostol"—a commercial prepn.—activated in oil, and irradiated ergosterol, activated in alcohol, when fed at the same vitamin D levels produced hypervitaminosis of the same degree of severity. Death from hypervitaminosis D results in enormous deposits of Ca in kidneys, heart musculature, etc., and in presence of urinary calculi. In exptl. hypervitaminosis there is a tendency toward diminished  $p_H$  of feces, diminished heart rate and, at death, atrophy of the thymus. BENJAMIN HARROW

Further studies of the chemical nature of vitamin A. JACK CECIL DRUMMOND AND LESLIE CHARLES BAKER. *Biochem. J.* 23, 274-91(1929); cf. *C. A.* 20, 1816.—Vitamin A is present in liver-oil concentrates in amounts so minute that direct attempts at its isolation by the ordinary chem. methods are of little use. BENJAMIN HARROW

Mineral hunger in sheep. Successful treatment by pellet-feeding method. B. C. ASTON. *New Zealand J. Agr.* 38, 10-6(1929).—Formulas are given for the prepn. of pellets, composed primarily of inorg. compds., for use as mineral supplements for sheep grazing on (1) areas deficient in Ca, (2) Fe-deficient pumice soils and (3) areas where a general mineral deficiency exists in the soils and vegetation. K. D. JACOB

High protein content of pasture. B. C. ASTON. *New Zealand J. Agr.* 38, 97-8(1929).—A brief review is given of the apparent relation of high-protein pastures to breeding difficulties in cattle, as indicated by the work of other investigators. K. D. JACOB

Whey paste as a pig food. M. J. SCOTT AND R. W. GRAHAM. *New Zealand J. Agr.* 38, 112-4(1929).—Pigs fed on whey scoured badly appeared to suffer much from cold and grew very hairy, but in general made satisfactory growth after reaching a wt. of 70 lb. Better results were obtained by supplementing the daily ration with 0.5 lb. of meat meal. Young pigs did not thrive on whey alone. The compn. of the solid and liquid portions of the whey was: dry matter 58 and 45, protein 6.6 and 5.2, chlorides (as NaCl) 2.4 and 2.1 and acidity (as HCl) 0.7 and 0.8%, resp. K. D. JACOB

Grape sugar as diet. A. BICKEL. *Arch. Verdauungs-Krankh.* 45, 16-9(1929).—Grape sugar is a slightly weaker secretory excitant than beet sugar. "Maizena" added to cow milk gives rise to a fine flocculent coagulum of the milk during gastric digestion. FRANCES KRASNOW

A new deficiency disease produced by the rigid exclusion of fat from the diet. GEORGE O. BURR AND MILDRED M. BURR. *J. Biol. Chem.* 82, 345-67(1929).—The data presented apparently "definitely settle the uncertainty as to the necessity for fats in the diet of the rat and prove not only that ingested fats have a beneficial effect upon the animal but that under the exptl. conditions used they are essential constituents of the diet. When dietary fats are reduced below a certain minimum, the rat develops a characteristic disease and dies at an early age." The disease is characterized by a caudal necrosis and is readily prevented or cured by the addn. of 2% of fatty acid to the diet. The non-saponifiable fraction of fats and also glycerol are ineffective. As little as 3 drops of fat daily has a measurable beneficial effect. With fat-free basal rations, storage fat can be almost entirely eliminated and it seems probable that the amt. of body fat can be controlled over a wide range by the addn. of minute quantities of fat to the diet. "If the effect is not due to the ordinary fatty acids, then we must look for a new substance of the nature of an  $Et_2O$ -sol. org. acid which must be present in exceedingly small amts. This acid would be classed as a vitamin until its isolation permitted the assigning of a definite chem. formula and name. No conclusion can be drawn from the data at hand and for the present this dietary deficiency will be spoken of as due to the absence from the diet of the acids present in fats." The fat-free diet used contained especially prepd. and purified casein, sucrose, a salt. mixt., vitamin B from extd. yeast and vitamins A and D from the non-saponifiable matter from high-grade cod-liver oil. A. P. L.

Physiology of the vitamins. VII. Hemoglobin, solids, sugar and chloride changes in the blood of vitamin-B-deficient dogs. C. J. STUCKY AND W. B. ROSE. *Am. J. Physiol.* 89, 1-17(1929); cf. *C. A.* 23, 3734.—Vitamin-B(2 or more factors)-deficient dogs

showed a somewhat greater degree of anhydremia than was noted in control dogs. In the advanced stages of vitamin-B deficiency hemoglobin increased 13.7%, blood total solids increased 5.7% and after the administration of vitamin B to the polyneuritic dogs, hemoglobin decreased 21.5% and total solids decreased 15.1%. Blood sugar and blood chlorides were essentially alike in the vitamin-B-deficient dogs and in the controls. There is evidence that vitamin B influences the  $H_2O$  intake of the animal. J. F. L.

**The nutrition of the white mouse. V. The experimental production of rickets in mice.** H. H. BEARD and ELIZABETH POMERENE. *Am. J. Physiol.* **89**, 54-7(1929).—Mice fed the Osborne, Mendel and Park diet with a low P-high Ca salt mixt showed definite rickets at the end of 7 days with evidence of spontaneous healing after 28 days. Similar results were obtained with the diet 2965 of Steenbock and Black. Osteoporosis was present in many cases, especially after healing had taken place. J. F. LYMAN

**Changes in the serum calcium of cats during fasting.** S. MORGULIS and ANNE M. PERLEY. *Am. J. Physiol.* **89**, 213-4(1929); cf. *C. A.* **23**, 3959.—Serum Ca remained unchanged in cats during the early fasting periods, and diminished only in the more advanced stages. J. F. LYMAN

**Changes in the bones of rats fed various diets.** MEIJIRO SAKURAI. *Sen i-kwai Med. J.* **48**, No. 3, 78-111, Abstract sect., 7-9(1929); cf. *C. A.* **23**, 3960.—The rib bones of albino rats reared upon diets commonly used for feeding horses were studied histologically. Group 1, fed a mixt. of barley 150, ground meat residue 30, starch 20 and NaCl 2 (contains enough vitamin A and P but deficient in Ca) developed rickets. A drop of cod-liver oil fed every other day made no difference. When this diet was supplemented with  $CaCO_3$ , so that the Ca/P ratio became 1/0.67, the bone development was normal. If the Ca value was increased to 5 times the above the bones showed porosity. This same high Ca diet produced slightly porous bones even when cod liver oil was fed. Group 2, fed a ration of oats 150, meat residue 30, starch 20 and NaCl 2, developed the bone changes of rickets. Supplements of cod-liver oil and Ca produced the same results as those in group 1. Group 3, fed a diet of wheat bran 100, meat residue 30, starch 70 and NaCl 2 (the Ca, P and vitamin A contents are identical with those of the preceding diet), also developed rickets. Cod-liver oil supplement in this case produced a normal bone, however. S. concludes that bran is more favorable for bone development than oats. C. M. McCAY

**Azotemia as a consequence of salt deficiency.** LEON BLUM, P. GRABAR and VAN CAULAERT. *Presse méd.* **36**, 1411-3(1928).—A deficiency in salt effects a decrease of the mol. concn.; this is compensated by an increase in urea. A. F. MEYER

**The vitamins in medicine.** CARLOS P. MATHEU. *Semana méd.* (Buenos Aires) **35**, 977-82(1928). A. F. MEYER

**Gossypol, progress report.** E. P. CLARK. *Oil & Fat Ind.* **6**, No. 7, 15-9(1929), cf. *C. A.* **23**, 2944.—White rats respond to the toxic action of gossypol, and may be used to det. physiologically the free gossypol content of cottonseed meal. Growth rates of rats fed upon diets contg. high levels of cottonseed meal are accelerated by a protein supplement. The growth rates are also influenced by the compn. of an added mineral supplement. Bound gossypol has no influence upon the growth rate of rats. Rats fed on autoclaved cottonseed meal prepd. by the Menaul process show growth rates inferior to those obtained with untreated meal. In live stock feeding the proper method of using cottonseed meal apparently is as a protein supplement. E. SCHERUBEL

**The digestibility and metabolizable energy of soy-bean products for sheep.** T. S. HAMILTON, H. H. MITCHELL and W. G. KAMMLADE. *Illinois Sta. Bull.* **303**, 237-95 (1928).—Digestion coeffs. apply to the edible portion of the feed only, and should not be used in connection with wts. of feed offered in computing the digestible nutrients of rations. Such coeffs. do not have a general applicability, since the inedible portion of the roughage will vary with the conditions under which it was grown or prepd. for the animal. Soy-bean straw and soy-bean hay are roughages of this character, and the use of the digestion coeffs. and metabolizable energy values obtained for them must be tempered by the above considerations. E. F. SNYDER

**The formation of creatine at the expense of protein substances.** EMILE F. TERROINE and P. DANMANVILLE. *Compt. rend.* **188**, 1439-41(1929); cf. Terroine and Mahler-Mendler, *C. A.* **22**, 973.—Expts. on pigs lead to the conclusion that in the course of growth alimentary protein material causes a formation of creatine which is the greater the smaller the N retention following its absorption. The classification of proteins according to their creatinogenic value is exactly inverse to their classification according to biol. value. G. TOENNIES

**Factors influencing calcium balance.** VERSA V. COLE, JOHN H. SPEER and FRED W. HEVL. *J. Am. Pharm. Assoc.* **18**, 36-42(1929).—For rats the amount of Ca barely

able to keep equil. in a Ca-deficient diet was about 4 to 5 mg. given as lactate. At this level the influence of systemic alk. on Ca, P and Mg balance was studied. With  $\text{CaCO}_3$  the animal came into equil. at about the same rate. This salt produces a better utilization of P than the lactate. Small addns. of alkali citrate to the Ca lactate induced better utilization of Ca and P. Alky. probably favorably influenced the Mg balances.

I. E. WARREN

Ultra-violet irradiation of food on a tonnage basis (DORCAS) 12.

## F—PHYSIOLOGY

E. K. MARSHALL, JR.

**Influence of spinach on gastric secretion.** KARL HANG. *Arch. Verdauungs-Krankh.* 45, 20-43 (1929).—A soup from 100 g. spinach produces an extraordinarily large rise of the HCl in 11 out of 15 cases. The increase in acid and quantity of secretion is not as great in hyperacidity as in hypo- or normal acidity. The aqueous ext. from 100 g. of spinach produced increased acid secretion in 8 out of 9 cases. The influence of the spinach remained unaffected by atropine. After a caffeine test drink, 2 of 4 anacidity cases showed free HCl, and one showed a higher value than that obtained after histamine. Spinach feeding is indicated in cases of hypo- or anacidity, but contraindicated in hyperacidity.

FRANCES KRASNOW

**Summit metabolism.** G. GIAJA. *Compt. rend. soc. biol.* 101, No. 23, 3-23 (1929).—A review. There is an extensive bibliography.

B. C. BRUNSTETTER

**A histologic study of the formation of bile pigment.** K. O. HALDEMAN. *Arch. Path.* 7, 993-1011 (1929).—The Berlin blue method for the demonstration of Fe-contg. pigment in the tissues provides a means of identifying the cells that are concerned with at least one stage of the conversion of hemoglobin into bilirubin. The intravenous injection of hemoglobin in dogs is often followed within an hour by a striking increase in the number of droplets of Fe-contg. pigment in the reticular cells of the bone-marrow and occasionally by a moderate increase in such pigment in the stellate cells of the liver. The connective tissue macrophages, or histocytes, are probably responsible for the local formation of bilirubin resulting from the injection of hemoglobin into the pleural cavity or under the scalp. The cells that contain an increased amount of Fe are all a part of the reticulo-endothelial system. Bone-marrow plays the major role in the formation of bilirubin with the liver, spleen and possibly the lymph nodes having a lesser part in this process.

HARRIET F. HOLMES

**The lactic acid in the blood.** F. MUSANTE. *Fol. clin. chim. microscop.* 1, No. 6; *Rev. sudamericana endocrinol., inmunol., quimioterap.* 12, 406-11 (1929).—The origin and transformation of lactic acid in the blood are discussed, a method of its detn. is given, and its role in the normal and abnormal organism explained.

A. E. MEYER

**TRENDELENBURG, PAUL: Die Hormone. Band I. Keimdrusen, Hypophyse, Nebennieren.** Berlin: J. Springer. 351 pp. M. 28; Linen, M. 29.60.

## G—PATHOLOGY

H. GIDEON WELLS

**Enzymes in the fluid of ovarian cysts.** I. Amylase. T. TACHIBANA. *J. Kinki Gynaecol. Soc.* 10, 1-14 (1927).

B. C. A.

**Splenic substance in Gaucher's disease.** F. EPSTEIN AND H. LIEB. *Klin. Wochschr.* 7, 1085 (1928).—Examination of the spleen in Gaucher's disease has never revealed the presence of cerebrin (phrenosin) as well as kersin (cf. *C. A.* 22, 3692).

B. C. A.

**Sugar tolerance in arthritis.** I. Chronic infectious arthritis. BENJAMIN H. ARCHER. *Arch. Internal Med.* 44, 37-46 (1929).—In 20 typical cases of chronic infectious arthritis no evidence was found of diminished sugar tolerance.

J. B. BROWN

**The reducing power of blood serum.** GIULIO BUCCIARDI. *Biochim. terap. sper.* 16, 196-204 (1929).—The reducing power of serum filtrates freed from proteins by the usual method was detd. (a) before hydrolysis and (b) after hydrolysis with 1.7% HCl for 20 min. at 120°; a gave the free sugar and b-a the potential sugar. (c) The reducing power of whole serum was detd. after hydrolysis with 1.7% HCl (total sugars); c-b gave the protein sugar. In the blood serum of diabetics there was no const. relation in the distribution of sugar among the various fractions. The administration of insulin to diabetics diminished the free sugar in the serum, slightly increased the potential and protein sugar and decreased the total sugar.

PETER MASUCCI

The cure of experimental pancreatic diabetes by surgical enervation of the suprarenal glands. A. CIMINATA. *Boll. soc. ital. biol. sper.* 3, 1251-60(1928).—The diabetic symptoms shown by depancreatized dogs disappear by surgical enervation of the suprarenal glands. Glucemia diminishes, glucosuria disappears, the threshold tolerance for carbohydrates increases and the dogs gain wt. even though the animals receive a mixed diet contg. carbohydrates.

Blood chemistry in eclampsia. Studies on uric acid. O. M. BERNARDI. *Boll. soc. ital. biol. sper.* 3, 1261-6(1928); cf. *C. A.* 23, 3509.—The av. uric acid content in the blood of normal women kept on a normal diet was 2.33 mg. %; that of normal pregnant women was 2.44 mg. %; and that of eclamptic women was 4.27 mg. %. P. M.

The relation between hypochloremia and vomiting. C. CIPRIANI AND G. C. DOGLIOTTI. *Boll. soc. ital. biol. sper.* 4, 308-9(1929).—Two clinical cases were studied. The hypochloremia met with in intestinal obstruction is to be attributed not to vomiting but to a state of intoxication which damages the regulating mechanism of chloride equilibrium.

Studies on oxalic metabolism. IV. The elimination of oxalic acid in certain forms of hyperglucemia. P. DE LUCIA. *Boll. soc. ital. biol. sper.* 4, 356-9(1929); cf. *C. A.* 23, 3971.—Hyperglucemia was induced in dogs by the administration of glucose *per os* or by subcutaneous injection, and by subcutaneous injection of adrenaline. There was a hyperoxaluria in hyperglucemia regardless of how it was provoked; the greater the hyperglucemia the greater the amt. of oxalic acid eliminated.

The nature of immunity. VI. The specific hyperreceptivity of tumors. AMILCARE ZIRONI. *Boll. soc. ital. biol. sper.* 4, 374-5(1929).—A theoretical discussion in which Z. advances the hypothesis that the complete removal of a tumor gives rise to a state of immunity and that the incomplete removal leaves behind a state of increased receptivity.

The cellular immunity and its influence on the pharmacodynamic action of cobra poison. J. SAINATI. *Inaugural thesis, Sao Paulo* (1928); *Rev. sudamericana endocrinol., immunol., quimioterap.* 12, 461(1929).—The poison of *Lachesis lanceolatus* has a stimulating action on the smooth muscle of the rabbit; in rabbits previously immunized against the poison no stimulation of the muscle was observed. The immunity is not only a humoral but also a cellular one.

Uric acid and calcium in the different stages of gout and rheumatism. F. RATHERY AND P. L. VIOLE. *Presse méd.* 36, 1073-5(1928).—Normal plasma contains 40-50 mg. uric acid per l. and 100 mg. Ca. The urinary elimination is 450-500 mg. for uric acid and 140 for Ca in 24 hrs. In myelogenous leukemia the uric acid in the plasma is unchanged, but the elimination is increased to 1.6 g. The elimination of Ca is lower. The uric acid in the plasma is low in acute gout and it decreases more, while the elimination is high; it has its origin in the tissues. The elimination of Ca is first low and increases during the attack to above normal; then it decreases again, when the uric acid is still increasing. In subacute gout the conditions of uric acid are the same, but less pronounced; Ca elimination is above normal. In chronic gout the uric acid in urine is high, Ca changing. In rheumatism no rules could be established.

Alkalosis and alkaline diathesis. R. GOIFFON. *Presse méd.* 36, 1109-11(1928).—A deflection toward higher alk. in the humors influences almost every organ in its activity or in the perfection of exchanges.

The physicochemical conditions of blood serum during nephritis. PR. MERKLEN, J. CHAUMERLIAC, J. GUILLAUME AND Mlle. ACHARD. *Presse méd.* 36, 1169-72(1928).—Variations of the Cl content in the plasma in the different forms of nephritis are described. A decrease in Cl is accompanied by an increase in uric acid. If the uric acid is const., an increase of the electrolyte exerts a decrease of the dissozn.

The magnesium halides and cancer. PIERRE DELBET. *Presse méd.* 36, 1473-7(1928).—Mg salts are recommended for cancer prophylaxis.

The physicochemical relationships of the diphtheria bacillus to the proteins of the animal organism. II. The toxic properties of the protein fractions and the biochemical formation of diphtheria toxin. V. N. KRISHANOVSKII. *Centr. Bakt. Parasitenk.* I Abt., 112, 161-75(1929); cf. *C. A.* 23, 1678.—The diphtheria bacillus reacts with the proteins in the medium surrounding it. A portion of the diphtheria bacillus of unknown chem. constitution, called the virulence factor, produces the strongest toxin. This factor has an affinity for fibrinoglobulin and to a less extent for albumin. Another fraction of the bacillus called the toxogenic factor can produce strong toxin from albumin. Hence virulence depends on the amt. of these factors in the cell plus the presence of fibrinoglobulin and albumin in the surrounding medium. Thus the yield of toxin depends on the physicochem. structure of the bacterial cell and the medium.

JOHN T. MYERS

**Arterial carbon dioxide pressure in cardiac dyspnea.** F. R. FRASER, C. F. HARRIS, R. HILTON AND G. C. LINDER. *Quart. J. Med.* 22, 1-20(1929).—In cardiac dyspnea there must be a stimulus at the cardiac center independent of the quality of the blood at the center which causes increased pulmonary ventilation with a lowering of the arterial  $\text{CO}_2$  pressure. The stimulus may be due to low O tension of the tissues in the center, the result of lowered minute vol. of the circulation. In pulmonary disease or severe congestion, in addn. to heart failure, the  $\text{CO}_2$  pressure is raised, because of inefficient pulmonary ventilation or gaseous exchange. This may mask the effect of the additional stimulus, because of the added  $\text{CO}_2$  stimulus at the respiratory center. In one case there was evidence of retention of non-volatile acids causing increased H-ion concn. and low arterial  $\text{CO}_2$ .

JOHN T. MYERS

**d-Lactic acid in the gastric juice.** TOKUYA KUBO. Kyoto Imp. Univ. *J. Kyoto Prefectural Med. Coll.* 2, 261-92(1928).—K. collected a large quantity of gastric juice from patients with various stomach diseases, prepd. Zn and Li lactates from the lactic acid contained in it and measured their optical rotation and the content of the  $\text{H}_2\text{O}$  of crystn. He found that d-lactic and inactive lactic acids are present as a mixt. Then he detd. the kind and quantity of lactic acid present in the stomach in gastric cancer, with 5 kinds of gastric juice classified according to acidity. In the stomach unaffected with cancer, the usual acid is only the fermented lactic acid, although lactic acid is almost always found if the acidity is larger than 20. In the stomach affected with cancer, calcn. from the rotatory power and the  $\text{H}_2\text{O}$  of crystn. of the Zn lactate shows that in usual cases  $\frac{1}{3}$  of the ordinary lactic acid is composed of d-lactic acid. That lactic acid contained in the stomach affected with cancer is independent of the acidity of the gastric juice or the presence or the absence of any food residue in the stomach was proved to be true even in the case of the patient to whom only  $\text{H}_2\text{O}$  was given. Hence, K. infers that the presence of d-lactic acid is peculiar to the stomach affected with cancer, and that this acid probably comes from the involved portion of the inner stomach wall. K. SOMEYA

**The cholesterol in pathological liquids.** BONNAMOUR, REVOL AND MISS ROUCHÉ. *J. méd. Lyon* 4, 5(1928); *Rev. prat. biol.* 21, 242-3.—The quant. distribution of cholesterol in various liquids and the pathol. conclusions to be derived from it are discussed.

G. TOENNIES

**Carbohydrate metabolism in eclampsia.** H. J. STANDER AND E. P. HARRISON, JR. *Am. J. Obstet. Gynecol.* 17, 17-27(1929).—There is a tendency toward hyperglucemia in most cases of eclampsia. In general the blood-sugar level remains fairly const. throughout the disease. Following eclamptic convulsions there is a slight rise in blood sugar. A patient may have such convulsions with the blood sugar at different levels and these levels are not greatly disturbed by the convulsions.

R. C. WILLSON

**Fluctuations in blood sugar during eclampsia. III. The relationship between the blood plasma sugar and the corpuscular sugar variations in eclampsia as shown by serial curves. Preliminary report.** PAUL TITUS AND E. W. WILLETTTS. *Am. J. Obstet. and Gynecol.* 17, 27-35(1929).—It is suggested that fractional blood-sugar values be detd., the sugar of the blood plasma and that of the corpuscles being considered separately. Preliminary results indicate that the circulating sugar which is most mobile or most readily available is in the plasma and that it is not until the corpuscles are deprived of their sugar that a convulsion occurs. The first evidence of recovery is an increase in plasma sugar; after this the plasma sugar values subside as the corpuscular sugar increases. These fluctuations and the eclamptic convulsions can be stopped at any point by the hypodermic administration of morphine and the intravenous administration of dextrose solns. **IV. Analysis of Titus-Willetts data to determine effects of anticoagulant on plasma-volume and cell-volume relationships.** H. D. LIGHTBODY. *Ibid* 36-7.—The variations in the reported sugar values for cell and plasma cannot be accounted for by alteration in cell vol. due to the use of varying amts. of salt anticoagulant provided the cell existence as a suspended particle is maintained.

R. C. W.

**An iodine survey of Nebraska.** W. H. ADOLPH AND F. J. FROCHASKA. *J. Am. Med. Assoc.* 92, 2158-60(1929).—I content of Nebraska water supplies was 8.8-30.0 parts per 100 billion; that of soils was 0-15 part per 100 billion. I content of foods compared favorably with the amts. found in non-goitrous regions.

R. C. WILLSON

**Importance of chlorides in the chemical semeiology of the cerebrospinal fluid in diseases of the nervous system in infants.** P. BOSIO AND G. B. SEGREZZO. *Riv. clin. pediatrica* 27, 203-19(1929); *J. Am. Med. Assoc.* 93, 244.—By estg. 7.22 g. per l. as the normal Cl value, there is an early and marked diminution in tuberculous meningitis (6.7-5.7). This decrease is less marked in other forms of meningitis. In cerebrospinal meningitis the Cl value rose to normal in direct proportion to the patient's improvement.

R. C. WILLSON

The specific dynamic action of protein in relation to mental diseases. K. E. APPEL AND C. B. FARR. *J. Nervous and Mental Diseases* 70, 43-50(1929).—In a series of 28 cases (26 with miscellaneous psychoses and neuroses) diminution of the sp. dynamic action of protein was found in 5 (1 early uncomplicated dementia precox, 4 toxic or nutritional factors). Other cases showed normal reactions.

The amino acid content of the blood in leucemia. ERNST WIECHMANN. *Munch. med. Wochschr.* 75, 1115-6(1928).—In leucemia the content of amino acids is normal in the plasma and erythrocytes and high in the leucocytes.

R. C. WILLSON

R. C. WILLSON

## H—PHARMACOLOGY

A. N. RICHARDS

Opium addiction. VI. The effect of abrupt withdrawal followed by readministration of morphine in human addicts, with special reference to the composition of the blood, the circulation and the metabolism. ARTHUR B. LIGHT AND EDWARD G. TORRANCE. *Arch. Internal Med.* 44, 1-16(1929).—In 4 cases 24-hour withdrawal resulted in mild symptoms and only negligible changes in basal metabolic rate. In 10 cases of 48-hour withdrawal severe symptoms resulted, with leucocytosis concn. of the blood and slight rise in cholesterol. In two cases albuminuria occurred. Blood  $pH$ , urea N and sugar did not change. The changes following readministration of the drug were also studied.

J. B. BROWN

The effect of calcium, potassium, and sodium chlorides and potassium and sodium citrates in certain cases of delayed healing. W. L. T. ADDISON. *Can. Med. Assoc. J.* 18, 700-2(1928).

A. T. CAMERON

Symptoms of nitrous oxide—oxygen anesthesia. THOMAS C. BONNEY. *Dental Cosmos* 71, 805-9(1929).

JOSEPH S. HEPBURN

The hepatotoxic action of the derivatives of phenylquinoline. RODOLFO DASSEN. *Semana méd.* (Buenos Aires) 36, 368-71(1929).—Cinchophen, atophanyl and atoquinal produce liver poisoning and jaundice in cases of insufficiency of the kidneys. The treatment consists in intravenous injection of a soln. of dextrose and insulin.

A. E. M.

A new substance for the treatment of tuberculous abscesses. ARESKY AMORIM. *Semana méd.* (Buenos Aires) 36, 403-16(1929).—Colloidal *Cu morrhuate* (Gadusan) was used with success.

A. E. MEYER

Purinopoiesis and purinolysis (uricopoiesis and uricolysis) produced by radioactive salts. SIMÓN LIBEDINSKY. *Semana méd.* (Buenos Aires) 36, 417-20(1929).—The injection of radioactive salts produces leucemia and consequently a large increase of purine derivs. in the urine. The fresh urine reduces Fehling soln. in the cold, but no more after some days. This is due to the presence of adenine, which later is oxidized to uric acid. A description of the *prepn. of adenine from tea leaves* is given. It reduces cold Fehling soln.

A. E. MEYER

Synthalin in the treatment of diabetes. B. VARELA FUENTES AND P. RUBINO. *Semana méd.* (Buenos Aires) 36, 1416-26(1929).—The glucosuria is reduced by synthalin, but it has no marked influence on the hyperglucemia. The max. dose for adults is 25 mg. daily. It exerts an injurious action on the liver.

A. E. MEYER

The avertine anesthesia. A. GALINDEZ AND I. GONÍ MORENO. *Semana méd.* (Buenos Aires) 36, 1637-43(1929).—Avertine gave good results in rectal application. In the case of decompn. of the substance, HBr is developed, which presents a serious danger.

A. E. MEYER

Further studies on the influence of electrolytes on the effectiveness of specific diuretics and on the normal secretion of urine. DANIEL BERGER. *Biochem. Z.* 209, 218-35(1929).—Filling the peritoneal cavity with 100 cc. of 1-2% urea soln. causes a powerful inhibition on the diuretic action of a sp. diuretic. The addn. of electrolytes to the urea soln. injected intraperitoneally depending upon the concn. at once restores the effectiveness of the sp. diuretic. Intraperitoneal injection of a 2% urea soln. without the diuretic eufhylline exerts a very negligible diuretic action in spite of the increased  $H_2O$  and urea content of the organism. The evidence therefore supports the view that the effectiveness of a sp. diuretic depends upon the electrolyte migration from blood into the tissues in the mobilization of water and the extreme sensitivity of kidney cells to these changes. This also applies to normal secretion of urine.

S. MORGULIS

Studies on the action of insulin together with cyanic acid. NOBUO HOSODA. *J. Biochem.* (Japan) 10, 383-8(1929).—Intravenous injection of KCN causes hyperglucemia in the rabbit. By the administration of insulin the hyperglucemia can be reduced to the normal level or even below that.

S. MORGULIS

Drugs from the Kamerun region. II. Dimone, bulule and meninga remedies

against snake bite and dysentery. C. G. SANTESSON. *Skand. Arch. Physiol.* 57, 1-11(1929).—Dimone is the leaf of a plant identified as *Jatropha strigosa*, a water decoction of which is used against snake bite. It contains some glucosic non-toxic substances but no demonstrable alkaloids, and chem. as well as physiol. studies fail to show any reason for its therapeutic action. Bulule is the bark of a large tree, *Kigelia acutifolia*, and is used in conjunction with dimone against snake bite. This likewise contains only a non-toxic glucoside but no alkaloids or tannins. This last fact is particularly significant because the bark is used as an adjunct to meninga as a remedy against dysentery. The meninga is likewise a bark but of an unknown tree, and aside from a harmless glucoside seems to contain no other substance. S. MORGULIS

Effect of the cinchona alkaloids on the sympathico-motor innervation of the rabbit uterus. TORSTEN STAKE. *Skand. Arch. Physiol.* 57, 52-76(1929).—The various cinchona alkaloids in very small doses increase the automatism and raise slightly the tonus of the uterus. In somewhat larger doses these substances produce inhibition and finally paralysis of the uterine contractions. This effect is generally not reversible, and the uterus does not respond even to  $\text{BaCl}_2$ . In large doses quinine causes an inversion of the adrenaline effect, which is now inhibitory, so that quinine must paralyze the sympathetic motor nerves. Quinidine and cinchonine exert the same action. Quinoline produces similar effects without, however, disturbing the action of  $\text{BaCl}_2$  on the muscles. Cinchophen can to a certain extent increase and prolong the motor effect of adrenaline. Eucupine is a general muscle cell paralyzer. S. MORGULIS

Effect of the cinchona alkaloids on the sympathico-motor innervation of the frog. TORSTEN STAKE. *Skand. Arch. Physiol.* 57, 77-105(1929).—Quinine-HCl has a vaso-dilating action, suppressing or weakening the vasoconstricting action of adrenaline. It alters the musculature of the vessels, however, so that it becomes more or less refractory to constrictive influences. Quinidine- $\text{H}_2\text{SO}_4$  in general acts in a similar manner but not so strongly, and the adrenaline effect is completely restored after washing with saline soln. Quinoline tartrate is the most potent vasodilator so that it inverts the adrenaline action most markedly, which thus also becomes a vasodilator. The normal adrenaline reaction, however, is quickly restored after washing with physiological saline. The same is also true for cinchonine-HCl. All these alkaloids thus act by paralyzing the motor portion of the sympathetic innervation. S. MORGULIS

Chlorophyll and the blood picture. EDUARD RENTZ. *Skand. Arch. Physiol.* 57, 121-37(1929).—Intravenous injections of chlorophyll into rabbits produce an unusually strong and persistent rise in the number of thrombocytes and a marked increase in the polymorphonuclear leucocytes. The sympathetic innervation, as well as the stimulating action of the chlorophyll on the blood forming elements of the bone marrow, may be involved. S. MORGULIS

The action of ephedrine. N. REINITZ. *Skand. Arch. Physiol.* 57, 138-58(1929); cf. C. A. 22, 2212.—The action of ephedrine on the intestine is partly inhibitory and partly motor. It appears as if ephedrine in very small amts. may increase the irritability of the parasympathetic nervous system. Large doses destroy the irritability not only of the motor-parasympathetic, but also of the inhibitory-parasympathetic system. This effect, however, is not entirely due to nervous influences but is actually accompanied by a diminished muscle cell irritability. Following a parasympathetic stimulant like pilocarpine ephedrine which ordinarily has a motor effect now produces a definite inhibition instead. This inversion of the ephedrine effect is regarded as evidence that in large doses ephedrine must have a paralyzing effect on the parasympathetic nerve endings of the intestine. S. MORGULIS

Studies on the cardiovascular effects of insulin. CARL E. RATHÄ. *Skand. Arch. Physiol.* 57, 243-328(1929).—Intravenous injection of insulin causes a diminution of the minute vol. of the heart. This diminution continues for some time and in certain cases is followed by a transient increase. A second injection does not affect the minute vol. as much as the first and may even be without any action. The reduction in the minute vol. is due to a diminution of the beat vol. of the heart. The blood pressure in the aorta falls for about 10-30 min. after an intravenous insulin injection, this fall being sometimes preceded by a brief rise in pressure. The fall in pressure is caused by the diminished minute vol and only very rarely also to vasodilation. Generally the fall in the aortic pressure is accompanied by a constriction of the vessels which may become so pronounced that it is responsible for the observed secondary rise in pressure, and this vasoconstriction is attributed to the outpouring of adrenaline under the influence of insulin. Immediately following an insulin injection the pressure in the pulmonary artery increases owing to a vasoconstriction. The occasional lowering of the pulmonary arterial pressure seems to be due to the adrenaline effect. Following an insulin injection the effect of vagus stimu-

lation on the heart is more or less reduced, but this diminution does not generally occur if adrenaline is injected before the vagus is stimulated. These cardiovascular effects of the insulin are shown to be due to changes in the K and Ca content of the circulating medium produced by the insulin.

The treatment of pernicious anemia with liver extract. CYRUS C. STURGIS, PAPHIAEL ISAACS AND MILLARD SMITH. *Ann. Internal Med.* 1, 983-95(1928).—A liver ext. prepd. according to the method of Minot, Cohn, *et al.*, produced the same effect on the regeneration of blood in 28 patients as had previously been noted to follow the daily administration of 0.5 lb. of liver daily.

Pharmacological study of amino-acid derivatives. VI. Action of histidine methyl ether. SHINGO GOTO. *Osaka J. Med.* 28, 195-206(1929); cf. *C. A.* 23, 2214.—*Histidine methyl ether*, m. 195-7°, prepd. by G., was tested pharmacologically. The effect is the same in type as that of monocyclic amino acid derivs.

The oligodynamic action of silver. RAÚL WERNICKE AND FERNANDO MODERN. *Anales asoc. quim. Argentina* 16, 158-69(1928).—See *C. A.* 23, 1441.

The hepatic lesions of barbiturism. TRÉMOLIÈRES, A. TARDIEU AND CARTEAUD. *Acad. méd.* 12, 26(1928); *Ann. hyg. publ. ind. sociale* 1929, 370.—The action of compds like diallylbarbituric acid and diallylmalonylurea is dealt with.

Danger of thallium acetate pomades. SABOURAUD. *Soc. franç. dermatol. et syph.* 1, 10(1929); *Ann. hyg. publ. ind. sociale* 1929, 372.

The action of the benzyl cinnamate on the anatomic focus. J. JACOBSON. *Arch. maladies appareil digestif* March, 1928, *Rev. prat. biol.* 21, 188-9.—Under the influence of the substance (Jacobson soln.) edema, congestion and infiltration recede. The cinnamic radical inhibits the development of staphylococci, streptococci, diphtheria bacilli and of certain races of colon bacilli. The benzyl radical neutralizes toxins, provokes a temporary vasodilation and has catalytic properties.

The action of benzyl cinnamate on ulcerations. ANON. *Rev. prat. biol.* 22, 191(1929); cf. preceding abstr.—The substance (Jacobson soln.) injected into the organism acts upon inflammatory lesions in such a manner that the irritation and compression at the level of the nerve endings and the consequent pain are lessened. The substance is more efficacious in cases of continuous pain than in cases of recurrent pain.

The combination of iron with liver extract in the treatment of anemia. I. HALLION. *Rev. prat. biol.* 22, 65-72(1929).

Optically active isomers of *N*-phenyl- $\beta$ -methylglycineamide-*p*-arsonic acid and their use in the resolution of ephedrine (FOURNEAU, NICOLITCH) 10. New series of anesthetics. Acylaniline derivatives (HARTUNG, MUNCH) 10.

## 12—FOODS

F. C. BLANCK AND H. A. LEPPER

Official inspections. Foods and drugs. JAS. M. BARTLETT. *Mc. Agr. Expt. Sta., Official Insp. Bull.* 131, 1-16(1929).—Of the 41 samples of shucked oysters, 3 contained excessive free liquids and were adulterated. N. Atlantic oysters contain an av. of 20% solids as against 16% for S. Atlantic oysters. N. Atlantic oysters are considered adulterated if the H<sub>2</sub>O content exceeds 16%. Twenty-three samples of sausage out of 61 were adulterated by the addn. of cereal. The addn. of 10% cereal to sausage increases the moisture content from 10 to 20%. Since some of the ready mixed sausage seasoners contain starch, mfrs. may unwittingly add starch in this manner. Of the 113 samples of *spirit of peppermint*, 24 samples were adulterated in that less than 10% of peppermint oil was present.

Ultra-violet irradiation of food on a tonnage basis. M. J. DORCAS. *Food Ind.* 1, 504-5(1929).—A mech. set-up of app. for irradiating foods to increase their vitamin D content. A thin layer of the product, 1/8 in. deep, flows on a moving belt and is exposed to ultra-violet lamps.

Fluorescence and conservation of irradiated foodstuffs. Infant foods. L. M. SPOLVERINI. *Riv. ital. actinol.* 2, 1-19(1927); cf. *C. A.* 22, 2189, 2592.—Ultra-violet irradiation of foods causes phys. and chem. changes tending to greater stability, and facilitates their conservation. The foods become more or less radioactive. With certain foods irradiation is harmful.

The permissible arsenic content of foods. E. WASSER. *Mitt. Lebensm. Hyg.* 20, 147-52(1929).—The max. As tolerance in foods should be 0.1 mg. per kg. A general discussion of the question of As in fruits.

**The detection of rye flour in wheat flour.** CH. SCHWEIZER. *Mitt. Lebensm. Hyg.* 20, 119-22(1929).—Rye flour contains a nearly const. amt. of *trifurclosen* and 10% of rye flour can be detected in other flours by the use of the Trifurclosen method (C. A. 23, 912). S. found the technic to be reliable and accurate. C. R. F.

**Chemical composition of certain food pastes and the modifications they undergo when boiled in water.** L. SETTMJ. *Atti accad. Lincei* [6], 8, 314-7(1928).—Results of analyses of various qualities of materials of the macaroni type are given. After being boiled in water, these substances exhibit phys. modifications resulting from the imbibition of water, and contain about 20% of sol. starch, 6% of reducing sugars calcd. as dextrose and appreciably less sol. N compds. than the original material. The fat present is not modified by the boiling. B. C. A.

**Heat coagulation of milk as a function of its acidity.** ARMAND TAPERNOUX AND K. KATRANJEFF. *Compt. rend. soc. biol.* 101, 828-9(1929).—Changes in acidity (degrees Dornic;  $p_H$  by quinhydrone electrode) and temps. required for coagulation of a mixed, pasteurized lot of milk, stored at 14°, were followed. As the acidity increased, the coagulation temp. decreased. B. C. BRUNSTETTER

**Alkali value of milk.** F. E. NOTTBOHM. *Milchwirtschaft Forsch.* 4, 336-51(1927).—The alkali value ( $Na_2O:K_2O$ ) of milk is 2-10; the value for colostrum is generally greater than 2. Toward the end of lactation lower values are obtained. Immediately after establishment of equil. or excessive values for Na the content of lactose falls and that of Cl rises. B. C. A.

**Determination of silicic acid in milk.** O. KETTMANN. *Milchwirtschaft Forsch.* 5, 73-106(1927).—Milk contains 1.6 mg. of silica per kg. (0.021% of the ash), with fairly wide variations independent of those of other ash constituents, but dependent on the silica content of the fodder. In colostrum the silica content is above the av. Inflammation of the udder greatly reduces the silica content of the milk. B. C. A.

**Detergent properties of alkaline dairy-washing compounds.** MILTON E. PARKER. *Am. J. Pub. Health* 19, 751-7(1929).—Chem. purity is vital if consistent cleansing action is to be assured. J. A. KENNEDY

**Rapid method for the analysis of butter.** N. CHARLIERS. *Chimie et industrie* 21, 931-6(1929); cf. Tchétéroff and C., C. A. 22, 4664.—The following method has been devised so as to retain the chief advantages of the Kuhlmann and Grossfeld method (C. A. 20, 2373) and permit of the detn. of the sapon. no. on the same portion of sample, and at the same time avoid the use of glycerol and also of EtOH (with the attendant complications in the technic) by substituting *n*-propanol: To 5 g. butter fat in a 300-cc. Erlenmeyer flask add 25 cc. *N* KOH (heat 1 l. propanol to boiling, add 60 g. KOH in small pieces, heat gently under a reflux condenser till soln. is complete, cool and keep in a brown-glass bottle contg. a few crystals of  $K_2CO_3$ ) which has been prepd. for at least 12 hrs., add a few glass beads, reflux 20 min., add 0.2 cc. of 2% phenolphthalein in propanol, titrate with *N*  $H_2SO_4$  and calc. the sapon. no.; add 31.8 *n* cc. distd.  $H_2O$  (*n* = no. of cc. *N*  $H_2SO_4$  in the sapon. no. detn.), 100 cc. of K stearate soln. (saponify 10 g. pure stearic acid with 4 cc. of 75% KOH in presence of 10 cc. of propanol and dil. to 1 l.), 5 cc. of 1:2  $H_2SO_4$ , 15 g. anhyd.  $Na_2SO_4$  and a little infusorial earth, shake, let stand 30 min., filter through a fluted filter, to a 125-cc. aliquot in a 500-cc. flask add 50 cc.  $H_2O$  and a few pieces of pumice stone, dist. 110 cc. and titrate with 0.1 *N* NaOH. If *k* = cc. NaOH and *l* = cc. NaOH of a blank detn. (preferably carried out on fresh cacao butter), the butyric no. is given by  $1.75(k - l)$ . The addn. of  $Na_2SO_4$  throws the propanol out of soln. together with the fatty acids higher than butyric; the amt. of propanol remaining in soln. is insufficient to dissolve any of the higher acids or to produce partial alcoholysis of the butyric acid; there is no danger of the propanol being oxidized by impurities, which would cause an error in the results obtained for the sapon. no. and butyric no.; the pptd. propanol carries down an amt. of butyric acid which varies with different fats, and even with different butters, but the addn. of K stearate is considered to make the amt. of butyric acid thus entrained const. The following butyric nos. were found: pure cow butter 19-22, cacao butter 0, coconut oil 0.77-1.22, palm oil 1.57, palmetto oil 1.75. Comparison of the results obtained by the present method and by the Lefmann-Beam, Kirschner, Kuhlmann-Grossfeld and xylene (Van Raalte) methods showed that the Charliers method can detect adulteration with at least the same degree of accuracy as the others.

A. PAPINEAU-COUTURE

**The effect of the method of preparation on the keeping qualities of butter.** E. HAGLUND, B. PLATON, E. WALLER AND E. SÖDERBERG. *Medd. Centralanstalt. försöks-vasendet jordbruks.* No. 347, Mejeriavdel. No. 37, 25 pp.(1929).—The investigation confirms the previous result that the keeping quality of butter decreases with increasing

acidity of the cream. The keeping quality is independent of the acidity of the butter plasma; this acidity is decreased by washing the butter; the washing does not affect the keeping quality. It is indicated that the washing only very slightly affects the acidity of the butter fat; that the  $p_H$  of the butter plasma is mainly detd. by the acidity of the cream at the time of churning; that the actual acidity of the plasma is not appreciably changed by the washing, and that consequently it is possible, by detg. the actual acidity of the butter plasma, to indicate the acidity of the cream from which the butter is produced.

M. A. DAHLEN

**Estimation of yeasts and molds in butter. Influence of the hydrogen-ion concentration of the medium on the mold and yeast counts.** P. CLERKIN. *J. Dept. Agr. Ireland* 28, 199-207(1929).—In detg. yeasts and molds in butter the  $p_H$  value of the medium must be reduced to about 3.5 before the yeast count can be considered to be entirely free from bacteria. At  $p_H$  4.5 a large no. of bacteria colonies were included in the yeast count. The H-ion concn. did not seem to have any marked effect on the mold count over the range studied ( $p_H$  3.5 to  $p_H$  6.5). A high yeast and mold count in butter indicates recontamination after pasteurization. Sixteen citations to the literature are given.

K. D. JACOB

**Modern manufacture of margarine.** H. W. VAHLTEICH. *Food Ind* 1, 436-40 (1929).

C. R. FELLERS

**Diffusion of sodium chloride in cheese.** O. MROZEK. *Milchwirtschaft Forsch* 4, 391-402(1927).—The distribution of NaCl and water after immersion of the cheese in salt soln. and slow ripening is described.

B. C. A.

**The occurrence of rennet in cheese.** CHR. BARTHEL, E. SANDBERG AND E. HAGLUND. *Medd. Centralanstalt. försöksväsendet jordbruks*. No. 342, Bakteriöl. avdel No 48, Mejeriavdel. No. 35, 15 pp.(1928).—A previous paper (C. A. 23, 448) described a method for obtaining the liquids from cheese, and discussed the study of these with a view to obtaining information about the ripening of cheese. The present work has demonstrated that one can show the presence of rennet in all except Emmen-thal cheese directly by coagulation means. The inactivity of the rennet enzyme in Emmen-thal cheese is probably due to the high scalding temp. used in prep'g this cheese. The ripening of this cheese must be due entirely to the proteolytic enzymes of lactic acid bacteria.

M. A. DAHLEN

**Action of rennin.** E. MUNDINGER. *Milchwirtschaft Forsch* 4, 369-90(1927) — "Degree of acidity" and  $p_H$  are both of importance in the prep'n. of rennin. Sunlight confers on rennin solns. the ability to decompose  $H_2O_2$ .

B. C. A.

**Evaluation of rennin.** E. MUNDINGER. *Süddeut. Molkerei-Ztg* 19, 4 pp (1927) — The influence of  $p_H$ , CaO and protein content, and dispersion is considered. B. C. A.

**The importance of control in mayonnaise manufacture.** D. M. GRAY, C. E. MAIER AND C. A. SOUTHWICK, JR. *Glass Packer* 2, 311-4(1929).—Mayonnaise is considered as a dispersion of an edible oil in a continuous medium. "Continuous" is used in contradistinction to "dispersed," the emulsion being thought of as a network extending in 3 directions. The egg yolk is more concd. at the surface of the oil particle than elsewhere in the aq. phase. This concn. or adsorption is greatly influenced by the quality of the egg yolk. The oil should have a free fatty content of not more than 0.05% and the Kreis test must be neg.; otherwise rancidity often results. The oil plus egg content must be at least 78% in order to comply with the Federal standard. Freezing destroys the emulsion. At best mayonnaise must be considered a semi-perishable product.

C. R. F.

**Glass-packed chicken. How it is prepared and processed.** C. R. FELLERS AND F. P. GRIFFITHS. *Glass Packer* 2, 315-8(1929).

C. R. F.

**The Bull method for the estimation of the fat content in fish, meat and other animal or vegetable products through extraction.** JOHN SEBELIEN. *Chem. Ztg* 53, 489-90(1929).—To 5 g. of the sample add 7.5 g. dried  $Na_2SO_4$  or 15 g.  $CaSO_4$ . This makes the fat more accessible to the solvent.  $CaSO_4$  is better for salted material. Shake this mass with 40 cc.  $C_6H_6$ , draw off 16 cc. of the clear fat soln. and place in the warm pan of the "percentage-balance." This balance is constructed so that the pan holding the fat soln. is surrounded by a metal cylinder contg. an elec. heating unit. Balancing is accomplished by riders on the other arm, which is graduated to read percentage of fat.

RUSSELL C. ERB

**Tryptic hydrolysis of haddock muscle.** ARTHUR M. WYNNE. *Contributions to Can. Biol. and Fisheries* [N. S.] 4, 319-41(1929).—Variations in the Foreman titration values obtained by titration of haddock muscle-trypsin digestion mixts are detd. Fish muscle that has been salted, smoked or treated with  $CH_3O$  vapor all are digested more slowly than the untreated muscle.

W. D. LANGLEY

**Storage of fruit juices without injury to color or flavor.** M. A. JOSLYN. *Glass Packer* 2, 271(1929).—Discoloration in grape juice is due to (1) enzyme action, (2) combination between 2 or more substances in the juice resulting in a brown colored substance or (3) oxidation by atm.  $O_2$  or  $O_3$  in soln. of some constituent in the juice resulting in a brown colored substance. Frozen grape juice retained its characteristic flavor and odor and suffered no deterioration during storage. The product is indistinguishable from fresh juice.

**Color solutions as sources of spoilage in beverages.** PAUL J. BEARD, MAX LEVINE AND J. H. BUCHANAN. *Glass Container* 8, No. 9, 22-4(1929).—Color solns. for use in beverages should be sterilized after bottling to prevent spoilage of the foods in which they may be used.

**Removing cream of tartar from grape concentrates.** P. H. RICHERT. *Glass Packer* 2, 285(1929).—In addn. to the usual settling and racking methods, the use of Ca salts yielding insol. Ca tartrate is described. The resulting sirup is alk. and has an objectionable burnt taste. Grape juice possesses an excess of neutral K tartrate over the bitartrate. The neutral salt is very sol. and remains in soln. in the sirup. Acids such as  $H_3PO_4$  react with this salt to form the relatively insol. bitartrate, which can be removed. By acidifying the sirup first, the desirable acidity is maintained.

**The causes of crystallization of raspberry sirups and means for prevention.** VL. STANEK AND P. PAVLAS. *Listy Cukrovar* 47, 575-82(1929).—A home prepn. which had been cooled to  $-2^\circ$  yielded 10 g. per l. of a mixt. of sucrose and glucose with one mol. of  $H_2O$  of hydration. Commercial prepn. yielded glucose only. The crystn. is caused by a high concn. of sugar, excessive cooling and an inversion of sucrose to glucose and fructose. Maintaining a concn. of sucrose below 60% and avoiding low temp. prevented the crystn. of sucrose. The crystn. of glucose is prevented by preventing inversion. The rate of inversion of sucrose from raspberries by invertase from yeast was studied. Inversion was prevented by boiling the sirup or juices for 10 min. The acidity varies with the degree of ripeness. Sour juices should be treated with  $NaHCO_3$  to decrease the acidity. Sirups made by different processes invert sucrose at the same rate. Sirups contg. 50% or more invert sugar showed cryst. deposits at  $0^\circ$  after a few days and crystn. continued (the total quantity of sugar present was 66%). Microscopic tests confirmed the actual trend of the large supply and may be used to predict the behavior of a sirup; all sirups which formed permanent crystals on a slide at the end of 1 hr. at  $0^\circ$  crystallized after 10-15 days in the large batches. The crystallizing sirups may be saved by mixing with sirups with less invert sugar so that the total invert sugar is below 50% in the mixt.

**Chemical composition of mustard and turnip greens and losses of iron in cooking.** A. M. FIELD, M. T. PEACOCK, R. COX AND I. P. EARLE. *West. Hosp. and Nurses' Rev.* 11, No. 5, 26-8(1928); *Expt. Sta. Record* 60, 190.—Turnip and mustard greens compared favorably with spinach in all respects and were markedly higher in Ca and Fe. When cooked in varying quantities of distd. water for 45 min., the losses in Fe varied from 5 to 25%, depending upon the vol. of water used. Tap water caused more than twice as great a loss of Fe as was caused by an equal vol. of distd. water.

**Sterilization of green fodder by liquids.** C. BRAHM, G. ANDRESEN AND R. PRILLWITZ. *Fortschritte Landw.* 3, 769(1928).—Fingerling's suggestion for preserving fodder materials with dil. HCl was tested, but it gave a product no better than ordinary silage at a greater cost. Analyses of the grass used, before and after treatment, and of the press liquors over a period of 9 months, showed that the HCl tended to disappear during storage, and was not able to prevent the occurrence of other processes than lactic acid fermentation, nor prevent the disappearance of lactic acid.

**Cyanogenetic glucosides in Acacia.** H. FINNEMORE AND W. C. GLEDHILL. *Australasian J. Pharm.* 9, 174(1928); *Quart. J. Pharm.* 1, 238.—The leaves of *Acacia glaucescens* Willd., *A. Cheelii* Blakely, *A. Cunninghamii* H. K. and *A. Doratoxylon* A. Cunn., which are used as fodder in Australia, all contain a cyanogenetic glucoside. None of them contains an enzyme capable of hydrolyzing it, so that it is only when stock eat at the same time other plants which contain such an enzyme, or have sufficient HCl present in their stomachs to hydrolyze the glucoside that poisoning of stock is observed. Fifty-eight other Australian species of *Acacia* were examd. and found not to contain a cyanogenetic glucoside.

**The feeding of minerals to cattle and pigs.** J. P. DREW AND D. DEASY. *J. Dept. Agr. Ireland* 28, 1-6(1929).—The results of expts. on the mineral requirements of pigs are tabulated, and previous investigations are discussed.

**Calcium and phosphorus carriers in live stock feeding.** JOHN M. EVVARD *Feed-stuffs* 1, No. 2, 10-1 (1929).—A mixt. of  $\text{CaCO}_3$  and  $\text{CaSO}_4$ , the latter being derived from bone as a by-product in the manuf. of  $\text{H}_3\text{PO}_4$ , is a more efficient source of Ca for the feeding of stock than either compd. alone. Because of its high F content (cf. C. A. 22, 2527) phosphate rock should not be used as a source of P and Ca. E. J. marizes and discusses the results of expts. showing the deleterious effect of F. The P of raw rock phosphate can be utilized by animals but, at present, the bone products seem to be the safest forms of P for animal feeding. K. I.

**Denatured raw sugar as a cattle food.** EGON KRAUS. *Listy Cukrovar* 47, 400-8 (1929).—A discussion. FRANK MARESH

**Toxicity of cyanogenetic linseed cake.** E. KOHN-ABREST AND M. QUENTIN *Chimie & industrie* Special No., 682-91 (Feb., 1929).—A discussion of the danger attending the use of cyanogenetic linseed cake, with detailed descriptions of the symptoms in a no. of cases of intoxication of cattle and sheep which were attributed to HCN from linseed cake. A previous article (C. A. 15, 3347) is also reproduced.

A. PAPINEAU-COUTURE

**Chemical composition of apple juices as affected by climatic conditions** (CALDWELL) 11D. Peroxidase reactions and new reagents [for detecting raw milk and rancidity of fats] (CASOLARI) 11B. Apparatus for the determination of  $\text{CO}_2$  in the respiration of apples (HARDING, *et al*) 11D. The coagulation of milk [by soap] (CHIÓ, REPETTO) 11A. Tea in northeast India (CARPENTER) 15. Buffer intensities of milk and milk constituents (WHITTIER) 11A. Report of the Imperial Entomologist [control of insects in stored wheat] (ISAAC) 15. Report of the Imperial Agricultural Chemist [adulteration of butter and ghee with animal fat] (HARRISON) 15. Report of the Imperial Agricultural Bacteriologist (JOSHI) 15. Frozen yeast (STAIGER, GLAUBITZ) 16. Chemical detection of vitamin C (GLASSMANN, POSDREW) 11E. Vacuum evaporating apparatus for milk, etc. (U. S. 1,721,760) 1. Preserving fatty and oily materials (Brit. pat. 303,059) 27. Spray desiccation of milk (Brit. pat. 303,576) 1. Float device for preventing milk or other liquids from boiling over when heated (Brit. pat. 303,372) 1. Apparatus and system of spray desiccation for materials containing vitamins (U. S. pat. 1,722,175) 1.

FERRÉE, C. J.: *De Sojaboon en duurzaam Sojameel*. Amsterdam: J. H. de Bussy. 96 pp. Fl. 2.50.

**Index to the Literature of Food Investigation. No. 1, March, 1929.** Compiled by Agnes Elisabeth Glennie for Department of Scientific and Industrial Research London: H. M. Stationery Office. 85 pp. 2s., net.

**Treating grain.** K. DIENST. Brit. 302,992, Dec. 24, 1927. Cleaned, washed and husked grain is passed through drying columns or vessels either directly or after sep. moistening or soaking, and is then heated to about  $70^\circ$ , cooled to about  $20^\circ$ , cleaned and finally milled.

**Bleaching and improving flour and other milling products.** VAMAN R. KOKATNAR and STROCKTON G. TURNBULL (to Pilot Laboratory, Inc.). U. S. 1,722,501, July 30. Flour or like material is treated with a small proportion of a compn. including an org. peroxide such as benzoyl, fumaryl or phthalyl peroxide and a flour "improver" such as ammonium lactate,  $(\text{NH}_4)_2\text{SO}_4$ ,  $(\text{NH}_4)_2\text{CO}_3$ ,  $\text{NH}_4\text{Cl}$ , tartaric acid or its salts,  $\text{MgSO}_4$  or fumaric and other unsatd. acids and their salts, to effect bleaching and other improvement in the properties of the flour. Several examples are given. Cf. C. A. 23, 220.

**Flour and bread-dough treatment.** CURTIS J. PATTERSON and CHASTAIN G. HARRIS (to Bakeries Service Corp.). U. S. 1,722,677, July 30. Tartaric, citric, lactic or other suitable non-toxic org. acid is added in proportion to bring the gluten of the flour to "optimum condition" during the formation of the dough.

**Baking powder.** L. WERN. Brit. 303,353, Dec. 31, 1927. A neutral alk. earth pyrophosphate such as that of Ca is used as a stabilizer and filler in baking powders and similar compns.

**Sterilizing and activating milk and other foods by ultra-violet rays.** JACQUES W. D. CHENEY (to Chesney Process, Inc.). U. S. 1,723,603, Aug. 6. The material treated is slightly acidulated and exposed to ultra-violet rays of not less than 2000 Å. U. while excluding air.

**Treating milk to remove objectionable volatile flavors and odors.** OTTO F. HUN-

**PIKER** (to Pfaudler Co.). U. S. 1,723,860, Aug. 6. After being standardized to a definite acidity, milk is rapidly circulated, continuously and repeatedly, at a high temp. and in a state of relatively fine subdivision, through a partial vacuum where it is treated with a current of air for removing undesirable flavors and odors, and is subsequently agitated and cooled to churning temp. An app. is described.

**Heat treatment of milk in cans.** ALBERT R. THOMPSON (to Anderson-Barngrover Mfg. Co.). U. S. 1,721,751, July 23. The cans are passed successively through a preheating chamber and a "preheat-holding" chamber, both at a temp. below that of sterilization and then through a sterilizing chamber in which a superatm. pressure is maintained, and then through a cooling chamber also under pressure. Various details of the app. are described. U. S. 1,721,752-3 relates to structural features of canning app.

**Powdered milk-serum product.** NINNI M. KRONBERG. U. S. 1,721,867, July 23. Skimmed milk is heated in an autoclave, then allowed to cool, inoculated with pure lactic cultures and treated with salts and saccharine substances, allowed to stand for a time, treated with a vegetable fat and a diastatic material and dried and powdered.

**Treating bovine milk to simulate mothers' milk.** THEODORE C. MANCHESTER. U. S. 1,723,188, Aug. 6. Pasteurized whole bovine milk is divided into major and minor proportions of approx. 85% and 15%, resp., cream equiv. to about 10% of the original quantity of milk is removed from the major portion, and the proportions of protein, lactose and other constituents are adjusted by abstraction and blending (details of which are described) to produce a final product contg. approx. 3.52% fat, 6.50% lactose, 0.74% ash and 12.34% solids.

**Milk for infant feeding.** LORE A. ROGERS (to the Government and people of the United States). U. S. 1,722,710, July 30. Milk is pasteurized by heating at about 62.5° for about 30 min., homogenized at a pressure of about 2800 lbs., then cooled to about 42.5°, inoculated with a milk culture of the *Lactobacillus* group and maintained for about 48 hrs. at a temp. of about 42° and to develop a pH of about 3.5 to prevent the growth of bacteria and yeasts in the milk.

**Cocoa-milk beverage.** C. E. NORTH. Brit. 303,187, July 27, 1927. A milk beverage with cocoa held in relatively stable suspension is prepd. by use of a gelatinous thickener and by heating the mixt. under pressure. Cf. C. A. 23, 2768.

**Almond milk food composition.** HERMANN HOFER-MASSARD. U. S. 1,721,522, July 23. Grated almonds 1 mixed with full cream milk 6 parts are pressed, the liquid is subjected to moderate heat for about 1.5 hrs. and the sirup is drawn off and may be mixed with water without sepn. of its ingredients.

**Chilling rolls for treating margarine emulsions.** A. A. POSTNI OFF and W. R. A. PICKERSGILL. Brit. 303,191, Sept. 20, 1927. Structural features.

**Preserving liquid egg material.** PULVO, LTD., W. F. BOLTON and C. V. B. READ. Brit. 303,530, July 4, 1927. Egg yolks or mixed yolks and whites are preserved by adding NaCl, boiling *in vacuo* at a temp. insufficient to cause coagulation (suitably about 55°) and then adding lactic acid. An app. is described.

**Canning meats.** JAMES W. RICHARDSON and PERCY W. WOOLLETT. U. S. 1,723,710, Aug. 6. S compds. are eliminated from meats before they are packed in cans by the action of flowing steam at a sufficiently high temp. to evolve and carry away gaseous sulfurous compds.

**Apparatus for drying fish or other foods.** W. H. HASLAM. Brit. 303,591, Oct. 21, 1927.

**Evaporating fruit juices, etc.** M. K. SERAILIAN. Brit. 303,956, Nov. 8, 1927. See Fr 644,180 (C. A. 23, 1899).

**Blanching celery and other green vegetables.** RODNEY B. HARVEY (to University of Minnesota). U. S. 1,721,595, July 23. C<sub>2</sub>H<sub>4</sub> is used in admixt. with air in quantity 100 to 100,000 times that of the C<sub>2</sub>H<sub>4</sub>.

**Crystallizing sweetmeats in circulating sirup.** A. G. HULME, BAKER PERKINS, LTD. and ANCIENS ÉTABLISSEMENTS A. SAVY, JEANJEAN, ET C<sup>IE</sup> SOC. ANON. Brit. 303,605, Nov. 7, 1927. An app. is described with various details of operative procedure.

**Coffee cakes suitable for making coffee beverage.** JOHN P. PAULY (to Measure-Rite Coffee Co.). U. S. 1,723,069, Aug. 6. Ground browned coffee is formed into a cake and the latter is baked until the adhesive material of the coffee grains unites and hardens.

**Flaked cattle food formed from cottonseed meal and molasses or similar materials** JOSEPH F. RUMSEY. U. S. 1,723,210, Aug. 6. Mech. details of manuf. are described.

## 13—GENERAL INDUSTRIAL CHEMISTRY

**Gas absorption.** SOC. DE RECHERCHES ET D'EXPLOITATIONS PÉTROLIFÈRES. Fr. 34,240, Aug. 30, 1927. Addn. to 612,386. The absorbent material, *e.g.*, charcoal, used in gas absorption is dried and cooled by submitting it to a closed cycle of gas cooled at one point of the cycle by contact with cold surfaces or other means.

**Separating mixed gases such as oxygen and nitrogen by progressive solubility.** WM. L. DEBAUPRE (to Samuel G. Allen, trustee). U. S. 1,722,458, July 30 The gaseous mixt. is introduced under pressure at an intermediate point in a tray section (of an app. which is described) and a solvent of different nature such as water is introduced into the upper end of the section to flow out of the bottom end; heat is added below and abstracted above the inlet, and the solvent is subjected to reduced pressure to free the constituent desired (the gaseous mixt. before compression being subjected to the solvent at the reduced pressure).

**Desulfurizing gases.** SOC. INTERNATIONALE DES PROCÉDÉS PRUD'HOMME-HOUDRY. Fr. 34,142, Aug. 8, 1927. Addn. to 639,774 (C. A. **23**, 678). The treatment of substances used for desulfurizing gases, *i.e.*, treating with reducing gas and then with air or O, is followed by blowing a reducing gas through it to decompose the small quantities of basic sulfates which are formed during the regeneration.

**Extracting acetylene from gas mixtures by use of acetonitrile as a solvent.** I. G. FARBENIND. A.-G. Brit. 303,068, Dec. 27, 1927.

**Chemical reactions between substances, one in liquid and another in gaseous form.** M. POLANYI and S. VON BOGDANDY. Brit. 303,900, Jan. 12, 1928. Substances which cannot be subjected to heating in liquid form (as in an inert solvent) are passed at high velocity and with continual renewal of the outer surface of the liquid, past vapor of another reaction substance. The method is stated to be suitable for effecting combination between org. substances and those which are only volatile at high temps such as Cu, Ag, C and metallic oxides. When the vapors of the heated substances are not sufficiently reactive their activity may be increased by superheating, use of elec. dis-

charges, etc. This is stated to be necessary in the case of substances such as As, Sb, Bi, S and Se. An app. is described.

**Separating oil and vapor from hot mixtures.** JOHN PRIMROSE (to Foster Wheeler Corp.). U. S. 1,723,748, Aug. 6. In treating materials such as hot mixts. from oil stills an initial sepn. of oil and vapor is effected by passing the mixt. into a portion of a closed chamber intermediate its top and bottom in rapidly flowing jets which impinge against surfaces within the chamber and are broken up with liberation of a portion of the vapor; oil from the broken jets is passed in film-like and broken streams through a lower portion of the chamber, vapor liberated from the streams is collected and mixed, without contact with the descending oil, with the vapor initially liberated in the chamber, and entrained oil is sepd. from the vapor mixt. in the upper portion of the chamber. An app. is described.

**Purifying chemicals for use in the manufacture of products containing active oxygen (such as peroxides and persalts).** WALTER WEBER and MAX JACOBI. U. S. 1,722,871, July 30. Catalytically acting substances such as small quantities of Mn and Cu compds. and exceedingly small traces of Pt or other heavy metal compds. which interfere with production of percompds. in good yield are removed from the starting materials such as borax or soda solns. by use of silica gel.

**Dispersions.** J. R. GEIGY A.-G. Fr. 658,180, Dec. 6, 1927. A mixt. in soln. of colloidal  $\text{SiO}_2$  and sulfite lye, such as is obtained in the manuf. of cellulose, is used as an emulsifying and colloid-protecting agent.

**Refrigerators.** PIERRE M. LE ROY. Fr. 657,735, June 26, 1928.

**Refrigerating apparatus.** ALBERT R. MCLEOD. Australia 14,675, July 26, 1928.

**Refrigerating apparatus of the absorption reversing type.** D. F. KEITH (to Perfection Stove Co.). Brit. 303,069, Dec. 27, 1927. Structural features.

**Refrigerating system of the absorption type.** SIEMENS-SCHUCKERTWERKE A.-G. Brit. 303,504, Jan. 5, 1928.

**Refrigerating system of the absorption type.** BALTZAR C. VON PLATEN, CARL GEORG MUNTERS and SIGURD M. BÄCKSTRÖM (to Electrolux Servel Corp.). U. S. 1,723,453, Aug. 6. Structural features.

**Condenser for refrigerating apparatus.** HAROLD A. GREENWALD (to Thomas C. Whitehead). U. S. 1,722,699, July 30. A heated medium such as a refrigerating agent is intermittently passed through a cooling conduit having a deliquescent substance such as solid  $\text{CaCl}_2$  in thermal contact with it, and a cooling effect is produced during the passage of the heated medium by evapn. of the liquid in the deliquescent substance, and moisture is absorbed in the latter when the heated medium is not in circulation.

**Mercury-forcing device for use in refrigerating apparatus, etc.** A. EINSTEIN and L. SZILARD. Brit. 303,065, Dec. 27, 1927. Structural features.

**Separator for refrigerating vapor and lubricating oil of refrigerating apparatus.** C. H. COOK AND SERVEL, LTD. Brit. 303,425, Sept. 3, 1927. Structural features.

**Insulating coatings on wires.** BRITISH THOMSON-HOUSTON CO., LTD., H. W. H. WARREN and A. T. WARD. Brit. 303,936, Oct. 22, 1927. An insulating coating is used which comprises a glycerol-phthalic acid resin (which may be plasticized with oleic acid and mixed with various other specified substances), and an oil varnish is afterward applied as an overlying coating.

**Electric insulation on wire.** ALLGEMEINE ELEKTRICITÄTS-GES. (to International General Electric Co.). Brit. 303,868, Jan. 11, 1928. Wire, before being insulated with vulcanized rubber, is coated with a lacquer formed mainly of a reaction product of polyhydric alcs. and polybasic acids and which may also contain drying oils or their acids to increase the elasticity of the lacquer.

**Electric insulating material.** MICAFIL A.-G. Brit. 303,125, Dec. 28, 1927. In forming insulation of layers of paper or woven fabric coated on one side with artificial resin, shellac or other insulating adhesive material, the other side of the paper or fabric is coated with other insulating materials such as oil, paraffin, asphalts or resins or their mixts.

**High-tension insulators formed of formaldehyde condensation products.** RHEINISCH-WESTFÄLISCHE SPRENGSTOFF-A.-G. VORM. W. LAHMEYER & CO. Brit. 303,883, Jan. 12, 1928. After formation and dehydration of the condensation product, it is cast while still liquid and hot, and is hardened by heating.

## 14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

**Operating experiences at the Sacramento filtration plant.** RALPH A. STEVENSON. *J. Am. Water Works Assoc.* 21, 929-40(1929).—The supply, taken at the junction of two rivers, is subject to rapid variation. The real problems relate to algae and turbidity. Alum and Cl, both manufd. at the plant, are used. Many details of operation are given. The results are considered satisfactory. D. K. FRENCH

**Simple test for delayed alum floc in filtered water.** FRANK E. HALE. *Am. J. Pub. Health* 19, 813(1929).—Flocculation is frequently induced by passage through the fine sand (60-120 mesh) used for concg. a sample for microscopic examn. To facilitate its recognition it is best to leave a fair-sized air bubble and rotate this around the cell several times. This gathers the floc into large masses of rather characteristic appearance. To distinguish the floc from ordinary amorphous matter, add sufficient "Alizarin S" (0.1% filtered soln. of com. Alizarin S, the Na salt of alizarinmonosulfonic acid) to give a slight color to the liquid. The air bubble is then rotated and the floc gathers all the dye and leaves the liquid colorless. Ordinary amorphous matter will not take up the dye in this fashion. The method also distinguishes delayed alum floc from Al in clay which is included in any chem. quant. method. J. A. KENNEDY

**Open and covered reservoirs at Washington.** D. C. CARL J. LAUTER. *J. Am. Water Works Assoc.* 21, 947-54(1929).—The advantages of the covered reservoir are strongly emphasized. D. K. FRENCH

**Protection of an impounded water supply from oil field drainage and irrigation water.** N. T. VEATCH, JR. *J. Am. Water Works Assoc.* 21, 955-62(1929).—Lake Wichita is the water supply for Wichita Falls. Its quality is soft and good. Lake Kemp, nearby, is extremely hard and unfit for domestic use. Surface drainage, influenced by nearby oil wells, is apt to be salty. It is important to guard Lake Wichita from such contamination. Methods proposed are outlined but no results are yet available. D. K. FRENCH

**Determination of the hardness of water by means of soap solution.** G. BRUHNS. *Chem.-Ztg.* 53, 469-70(1929).—A discussion of the method of Boutron and Boudet. RUSSELL C. EBB

**Colon bacilli in pressure tank water systems.** W. L. MALLMANN. *J. Am. Water Works Assoc.* 21, 944-6(1929).—A condition is cited where all tests of tank water confirmed for *Escherichia coli*. A sample taken directly from the supply was free from *B. coli*, indicating that the tank was the source of contamination. D. K. FRENCH

**The *B. coli* content of mineral waters.** L. GARBANO. *Zentr. ges. Hyg. Grenz.* 18, 773-4(1928); *Wasser u. Abwasser* 25, 227.—In 6 mineral waters small nos. of *B. coli* gradually increased in no. for several days; in very hard waters the rate of increase was less, while in soft water there was no increase. Cl, NO<sub>3</sub>, PO<sub>4</sub> and alky. were beneficial while SO<sub>4</sub> was inimical. *B. typhosum* died out in a few days in mineral water. C. R. FELLERS

**Mineral analysis of the waters of Kama and its tributaries.** A. A. VAROV. *Bull. biol. Research Inst. Univ. Perm* (Russia) 35-49(1928).—Samples were taken at the end of July and at the beginning of August when the mineral concn. of the water is about 3 or 4 times as great as that in spring and about 1/3 to 1/4 that in winter. The dependence of elec. cond. of the water upon its mineral content is established. Analyses are given. REA MAIZEL

**Boiler water conditioning.** A. F. JOSEPH AND J. S. HANCOCK. *J. Am. Water Works Assoc.* 21, 975(1929).—Polemic with Hall, *et al.* (*C. A.* 23, 3287). D. K. F.

**Materials for cast-iron [water] pipe joints.** W. C. MABEE. *J. Am. Water Works Assoc.* 21, 995-1004(1929). E. H.

**A few details of sewage treatment in Germany and England.** SAMUEL A. GREELEY. *Municipal News and Water Works* 76, 73-4(1929).—In the Ruhr valley oil is removed from suspended particles by 3 to 5 min. aeration. The tendency in England is toward longer displacement periods in settling tanks. Sep. sludge digestion with gas collection seems to be growing in favor and such tanks are being used in the Ruhr valley in conjunction with 2-story tanks having small sludge compartments. C. C. R.

**The sewage-disposal plant of Aurora, Ill.** L. R. HAWSON. *Municipal News and Water Works* 76, 141-5(1929).—This plant, being constructed on the unit plan, is to serve a population of 75,000 people and treat 6,500,000 gal. per day by 1940. The intercepting sewer is 32,200 ft. in length, varying in size from 18 in. to 69 in. The plant is to consist of mechanically cleaned coarse screens and grit chamber, sludge-

digestion tanks, sludge-drying beds, pumping station and sprinkling filters. The gas from digestion tanks is collected and used for heating the main building and for heating water that is circulated through the digesters to maintain a uniformly high temp. at all times.

C. C. RUCHHOFF

**Scarborough sewage-disposal plant.** W. D. PROCTER. *Can. Eng.* 56, 486(1929).—The plant is a spiral-flow activated-sludge type and includes coarse bar screens, detritor, aeration tanks, settling tanks and glass-covered sludge drying beds. Provision has been made for the future addition of separate sludge-digestion chambers. The capacity is one million g. p. d.

E. HURWITZ

**The Dunbar sewage filter bed.** ANON. *Municipal News and Water Works* 76, 151-3(1929).—Expts. were conducted at the Texas Eng. Expt. Station with a type of filter developed by Dunbar. The filter consists of several layers of stone in varying sizes and thicknesses. At a rate of 2,000,000 gal. per acre per day there is a 5-day B. O. D. reduction of 85%. For good nitrification and high dissolved O in effluent the optimum rate should be 1,300,000 gal. per acre per day. The filter clogs after application of 8,000,000 gal. of settled sewage per acre of bed surface. Resting of the filter bed for about 36 hours is necessary to allow drying and removal of solids from surface.

C. C. RUCHHOFF

**Sewage purification with activated sludge.** AD SEISER. *Ergebnisse Hyg. Bakt. expil. Therap.* 9, 343-84(1928); *Wasser u. Abwasser* 25, 246, cf. C. A. 22, 2225.

C. R. FELLERS

**Experiments on the dewatering of sewage sludge with a centrifuge.** C. E. KEEFER AND HERMAN KRATZ, JR. *Sewage Works J.* 1, 120-45(1929).—Expts. conducted at Baltimore, Md., indicate that sludge from sep. sludge-digesting tanks can be dewatered at a rate as high as 42 gal. per min. The removal of dry solids averaged 65.1% and moisture in the cake was 71.05%. Well digested sludge can be dewatered more readily than semi or undigested sludge. The centrifuge effluent contained 2.7% solids and had a 5-day B. O. D. of 10,000 p. p. m. Several methods for disposal of the effluent (none was entirely satisfactory) are discussed. The cost of dewatering Baltimore sludge with a centrifuge is \$1.33 per cu. yd. as compared with \$1.30 for air drying on sludge beds. The article includes a historical summary of the development of the Shaefer-ter Meer centrifuge used and a detailed description of the mechanism and operation.

E. HURWITZ

**Digestion of activated sludge.** WILLEM RUDOLFS AND H. M. HEISIG. *Sewage Works J.* 1, 146-59(1929).—Semi-plant-scale digestion expts. were conducted at Milwaukee over a period of 288 days. After 20 days activated sludge was added daily in definite vol. Decompn. of volatile matter added as activated sludge amounted to 49% fat 36%, N lost 32%. The digestion schedule for the first 106 days equaled 17½ days. Good, readily draining sludge was produced. The digestion schedule for the whole period of 288 days equaled 23 days. The authors conclude that activated sludge digests more rapidly than fresh sewage solids and requires no greater digestion capacity.

E. HURWITZ

**Gas production from sewage sludge.** S. I. ZACK AND G. P. EDWARDS. *Sewage Works J.* 1, 160-86(1929).—A critical discussion of data obtained on gas production in lab. expts. and on plant scale by American and European investigators. A summary of data on gas production for the installations discussed is contained in a table. Lab. data indicated that the amount of gas produced under conditions of alternate pressure and vacuum and under a continuous vacuum of 15 in. Hg was the same as that obtained at atm. pressure. General conclusions from all studies are: optimum  $p_n$  between 6.5 and 7.6; optimum temp., 77° F.; av. compn. of gas, methane 75%,  $CO_2$  20%, N and other gas 5%; B. t. u. per cu. ft. 700-800. A list of references is included.

E. HURWITZ

**Modern systems of garbage disposal.** ANON. *Can. Eng.* 56, 497(1929).—Report of the commissioner of streets shows that 160,000 tons of garbage was incinerated at the four Toronto plants. The article gives descriptions of the machinery at each plant and compares their costs of operation over a number of years.

E. HURWITZ

**The Beccari plant at Scarsdale, N. Y.** ARTHUR BONIFACE. *Municipal News and Water Works* 76, 75-8(1929).—The plant designed to treat the garbage from a high-class residential population of 10,000 people consists of an eight-cell unit. Each cell has a capacity of 20 cu. yards. The gas outlet from the cells is connected to a washing chamber in which a 1:500 soln. of  $KMnO_4$  is sprayed for odor control. Before the cells are charged the garbage is treated with about 1.5% of lime and an  $(NH_4)_2SO_4$  soln.

C. C. RUCHHOFF

**Results obtained in phenolic wastes disposal under the Ohio River Basin Interstate Stream Conservation agreement.** F. HOLMAN WARING. *Am. J. Pub. Health* 19, 758-70(1929).—W. discusses (1) location of by-product coke ovens, (2) source of phenolic wastes, (3) effect of phenolic wastes upon public water supplies, (4) experiences with phenolic wastes and early efforts of industry to eradicate them, (5) application of industrial science to the problem, (6) reaction of the public to the program, etc. Data on phenol removal are given for Ohio, Ky., W. Va. and Penn. **Discussion.** WM. L. STEVENSON. *Ibid* 817-8; C. A. HOLMQUIST. *Ibid* 819-20; ELLIS S. TISDALE. *Ibid* 820-2. J. A. KENNEDY

**Effect of atmospheric pollution upon incidence of solar ultra-violet light.** J. H. SHRADER, MAURICE H. COBLENTZ AND FERDINAND A. KORFF. *Am. J. Pub. Health* 19, 717-24(1929).—Solar ultra-violet light has been measured by the lithopone method of Clark and checked by 3 other chem. methods. Dust-cups and koniometer measurements indicate that atm. pollution is heaviest in the center of the city and falls off to approx. one sixth as much in the country. The amt. of ultra-violet light in the country is 50% greater than in the city. The amt. of settled dust on the top of a tall city building was materially less than at street level, and the incidence of solar ultra-violet light on the building was greater than at street level. Measurements made on "clear" days showed somewhat greater incidence of ultra-violet light than on cloudy days. The passage of ultra-violet light through confined air artificially polluted with fuller's earth, street sweepings and lamp black, resp., shows that they are increasingly effective in the order mentioned in occluding solar ultra-violet light. **Conclusions:** (1) The lithopone method is dependable for field use. (2) The belief that atm. pollution occludes ultra-violet to a very great extent is well founded. (3) The constituents of atm. pollution in summer are greater in quantity and different from those in winter. (4) Skyshine is equiv. to about 70% direct sunshine in content of ultra-violet light. (5) C as tarry products is materially more inhibitive to the incidence of ultra-violet light than siliceous materials. J. A. KENNEDY

**Treating waste water from Reading gas plant (KUNBERGER) 21.** Pharmacies [and medicinal springs] in Czech Silesia (DRUCE) 17. An I survey of Nebraska (ADOLPH, PROCHASKA) 11G. The electrolytic protection of Fe (VAN WULLEN-SCHOLTEN) 4.

**Mineral waters.** SCHERING-KAHLBAUM A.-G. Fr. 657,778, Nov. 21, 1927. An artificial mineral water is made by dissolving Fe salts such as  $\text{FeSO}_4$  simultaneously with substances capable of forming  $\text{CO}_2$ .

**Device (suitable for use adjacent faucets) for filtering water through activated carbon, etc.** GEORGE C. LEWIS. U. S. 1,723,564, Aug. 6. Structural features.

**Clarifying and softening water.** MOXIE L. FRISCHER (to Western Boiler Compound and Chemical Co.). U. S. 1,722,137, July 23. A soln. for clarifying and softening water comprises an aq. soln. of a water-softening agent,  $\text{Al}(\text{OH})_3$ , and sufficient  $\text{NaF}$  to dissolve the  $\text{Al}(\text{OH})_3$  and prevent pptn. of Al compds.

**Softening water.** EDWARD T. TURNER. U. S. 1,722,603, July 30. Hard water to be softened is passed through softening material such as zeolite or glauconite capable of taking up substances which harden the water and the softening material is regenerated by the action of sea water and then cleansed with clear water. An app. is described.

**Apparatus for softening water with zeolites.** CARL H. NORDELL (to Permutit Co.). U. S. 1,722,938, July 30. Structural features.

**Forming milk of lime and mixing it with water in desired proportions.** WALTER H. GREEN (to General Zeolite Co.). U. S. 1,722,571, July 30. An app. is described.

**"Deactivator" apparatus for removing corrosive gases from water, etc.** PERRY WEST (to Elliott Co.). U. S. 1,723,105, Aug. 6. Structural features.

**Accelerating sludge digestion for sewage treatment.** MAX PRÜSS. U. S. 1,722,945, July 30. The sludge is held in a closed container in which heavy portions of the sludge settle, and material deposited at the bottom of the container is elevated to a point adjacent but below the surface whence it again descends, all without introducing air below the surface.

## 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

**Report of the Imperial Agricultural Chemist.** W. H. HARRISON. Agr. Research Inst., Pusa, *Sci. Repts.* 1927-28, 30-9(1928).—*Effect of fertilizer constituents on the quality of sugar-cane juice and gur:* Fertilizing with  $K_2O$  yielded juices which from November to February had the highest coeff. of purity and contained the largest amt. of sucrose and the lowest of glucose.  $(NH_4)_2SO_4$  gave the lowest results for purity and sucrose and the highest for glucose. Superphosphate gave results inferior to  $K_2O$  but superior to  $(NH_4)_2SO_4$ . Mustard cake was superior to cyanamide and  $(NH_4)_2SO_4$ , particularly in the latter stages of growth. Cane grown without any fertilizer gave juices which were inferior in quality to those produced with  $K_2O$ , but in all cases they were superior to the juices produced with the other fertilizers. *Adulteration of butter and ghee with animal fat:* The following test was devised for the detection of animal fat in butter. Dissolve 1 g. of dry butter fat in 3 cc. of anhyd.  $Ac_2O$  and add 4 cc. of 93 % EtOH. Maintain the mixt. at  $30^\circ$  for 30 min. when the formation of a ppt. indicates adulteration with animal fat. The test is effective for all cow butters and any buffalo butter from animals not fed on cottonseed. Butters which do not pass this test are subjected to another test in which 1 g. of the fat is dissolved in 4 cc. of anhyd.  $Ac_2O$  and 3 cc. of 93% EtOH is added, the mixt. being maintained at  $30^\circ$  for 30 min. Under these conditions all butters from buffaloes fed on cottonseed are shown to be genuine, whereas the addn. of 10% animal fat, even to cow butter, gives a positive reaction. The first test will detect 10% of added vegetable fat, but the second test will not detect a 50% addn. *Experiments on the curing of tobacco:* Indian varieties of uncured tobacco leaves contain more nicotine and starch than American varieties, and the upper leaves of the plants invariably contain more nicotine and starch than the lower ones. Curing has little effect on the nicotine content of tobacco but causes a marked decrease in starch. Destruction of starch seems to be related to quality, since the best samples of cured leaf have the lowest starch content. *Estimation of the  $p_H$  values of soils by means of the antimony electrode:* Agitation is not necessary in detg. the  $p_H$  of soils by means of the Sb electrode. With the liquid in the quiescent state there exists the relation  $p_H = 20.042\text{obs.} - 0.469$ . Definite reproducible  $p_H$  values can be obtained if the Sb electrode is placed in the moistened soil contained in a glass vessel having a porous bottom so that it can be connected by means of a salt bridge to the reference cell. The values obtained in this way are practically the same as those obtained by the H electrode and are very similar to those given by the ext. obtained after settling a soil emulsion for 24 hrs. *Base exchange and soil acidity:* The results of preliminary expts. support the view that soil acidity is due to an insol. colloidal acid which is assocd. with surface-active H and basic cations. The colloidal acid seems to be tribasic, the acidity of a soil depending on the extent to which this compd. is neutralized by bases.

K. D. JACOB

**Report of the Imperial Agricultural Bacteriologist.** N. V. JOSHI. Agr. Research Inst., Pusa, *Sci. Repts.* 1927-28, 40-55(1928).—*Nitrogen fixation in soils:* Analyses of samples of soil taken monthly to a depth of 1 ft. showed that the total N content is highest in soils fertilized with green manure and superphosphate, followed in order by soils fertilized with superphosphate, farmyard manure and green manure, resp. Positive evidence that *algae* fix a certain amt. of N in soils was obtained in lab. expts. under conditions eliminating the possibility of symbiotic action with bacteria. *Nitrification in soils:* If the nitrifying flora is not active in the soil, the chief loss of N that occurs when large amts. of N are concd. in the soil as a result of spreading the fertilizer on the field is due to volatilization of  $NH_3$  when the temp. is higher than  $28^\circ$ . Very little N is lost at temps. below  $23^\circ$ . Results are given of *nitrification expts. with  $CaCN_2$*  on several types of Indian soils. In general, nitrification of cyanamide was slower than that of  $(NH_4)_2SO_4$ . Nitrification of *artificial farmyard manure* was slower than that of natural farmyard manure. *Refuse from the distn. of mahua flowers*, contg. 2% org. N, also nitrified more slowly than natural farmyard manure. As indicated by  $CO_2$  respiration expts., addn. of  $NaNO_3$  to the soil hastened the decompn. of mahua cake, but it was still inferior in this respect to mustard cake. *Diammonphos* and *Nitrophoska* nitrified as rapidly as  $(NH_4)_2SO_4$  in Pusa soils. *Effect of S and S compds. on nitrification:* When applied in concns. of 0.1 to 0.25% with mustard cake or  $(NH_4)_2SO_4$ , S and  $Na_2S_2O_3$  delayed nitrate accumulation in the soil for about 2 weeks, the effect completely disappearing after this period. In soils contg. 0.1% S from  $Na_2SO_3$  nitrate accumulation was delayed for 2 weeks, but when the concn. was increased to 0.25% the inhibitory effect persisted for over 16 weeks. Data are given on the effect of continued application of

various fertilizers on the N content, nitrifying power, CO<sub>2</sub> production and cellulose-destroying power of soils. Soils fertilized with green manure and superphosphate had the highest N content and the greatest cellulose-destroying power. Nitrifying power and CO<sub>2</sub> production were not affected by the fertilizer applications. *Silage investigations*: Maize silage developed acidity more rapidly and to a greater degree than *juar* silage and also contained a greater no. of bacteria during the first stages. Maize silage contg. a high percentage of H<sub>2</sub>O developed acidity more slowly than that made from maize with a lower H<sub>2</sub>O content. A method was developed for the *manuf. of vinegar* from cane and palm juice, gur, molasses, etc. A concn. of 7% AcOH was obtained in 4 days at 30° by inoculating these materials with *B. aceti*. Cinnamaldehyde and eugenol, in concns. of 1:2000 and 1:500, resp., prevented growth of spoilage organisms in unheated ripe *mango juice*, while in each case the concn. necessary to prevent spoilage was reduced 50% by heating the juice to 100°.

K. D. JACOB

The soils and vegetation of the Troitzk region, Ural Province. V. V. NIKITIN. *Trav. inst. recherches biol. Univ. Perm* (Russia) 2, 109-430(1929).—N. gives a complete picture of the soil formation process in the region, analyses of the parent material, ground waters, water-sol. salt content, mode of salinizing certain areas, the physicochem. characters of the process of salinizing, solonetz and solodi. The geologic formations of the region, and methods of ameliorating the alkali soils are described. An English summary (424-430) is given.

J. S. JOFFE

The nature and origin of the soils of Madagascar. HENRI ERHART. *Compt. rend.* 188, 1561-3(1929).—A detailed discussion with regard to the laterites, marls and clays.

E. F. SNYDER

Reclamation of moss land in Dumfriesshire. JOHN GILLIES. *Scottish J. Agr.* 12, 126-39(1929).—Any form of lime capable of neutralizing soil acidity was effective in moss land reclamation, but no form was more effective than ground limestone. Phosphates gave better results than lime, and phosphates without lime were much more effective than lime without phosphates, combinations of the two being more effective than either alone. Ground mineral phosphates were as effective as the various grades of basic slag. Synthetic silico-phosphates were very effective. The mol. compn. of the phosphates may have an important bearing on their value in the reclamation of moss lands. Potash and sol. N compds. had no visible effect in promoting the growth of grass on this type of land.

K. D. JACOB

Mineral composition of the soil as a factor in soil classification. J. HENDRICK AND G. NEWLANDS. *Proc. 1st Intern. Cong. Soil Sci.* 4, 183-6(1927).—An outline of the process for sepg. the minerals in the fine-sand fraction of soils by means of bromoform is described. The proportions of the various minerals present serve as a means of classification of soils according to origin. Characteristics of the parent rock are retained in cultivated soils.

B. C. A.

Scottish soil types with special reference to North-East Scotland. G. NEWLANDS. *Proc. 1st Intern. Cong. Soil Sci.* 4, 187-92(1927).—The general characteristics of the profiles of Scottish soils are typical of the podsol type. Further subdivision of this type is possible on the basis of org. and moisture contents, texture, and chem. compn.

B. C. A.

Substances removed by the drainage from a Scottish soil. J. HENDRICK AND H. D. WELSH. *Proc. 1st Intern. Cong. Soil. Sci.* 4, 163-71(1927).—The small loss of nitrate from cropped soils even when highly fertilized was noteworthy. The amt. of Na in the drainage water was nearly as great as that of Ca, although the respective proportions of these 2 bases in the total replaceable bases of the soil were 4.5 and 85%. No appreciable amts. of phosphates were found in the drainage even where phosphatic fertilizers were used. The leached sulfate was increased by liming, presumably as a result of stimulated bacterial decompn. of the soil org. matter. In the chalk-free soil examd. considerable amts. of silica appeared in the drainage.

B. C. A.

The washing-out of chloride [added to soils]. H. J. WITTEVEEN. *Landb. Tijdschr.* 40, 528(1928).—In a field expt. in the wet winter of 1926-27, chloride added as heavy applications of 20% potash salts was soon washed out. Chloride was added at the rate of nearly 500 and 600 kg. per hectare, and samples were taken every 4 weeks to a depth of 20 cm. After 2 months only 100-130 kg. of chloride per hectare remained in this depth, and further washing out took place in the following months. It was concluded that by seed time most of the added chloride would be out of reach of all but deep-rooted plants, and thus would not be harmful.

B. C. A.

Relationship between stability of soil structure and its colloid and sand content. A. T. TYULIN. *Rept. Dept. Agr. Chem., Perm* 2, 22(1928).—Stability is related directly to the colloid and inversely to the sand content. Four chernozem and 2 podsol soils

were compared, stability of structure being measured directly by washing samples with a const. pressure of water, and colloid content estimated from adsorption capacity. The product of adsorption capacity and sand content varied as between the 2 types of soil, but was roughly const. within a type. Na acetate treatment increased the amt. of colloid and decreased sand;  $\text{FeSO}_4$  had the opposite effect. B. C. A.

The composition of soil suspensions of various degrees of dispersion in the steppe, solonetz and podsolized types of soil. L. P. BELYAKOVA. *K. D. Glinka Memorial Vol.* (Leningrad Agr. Inst.,) pp. 91–162(1928).—The component particles of the suspensions of various degrees of dispersion resemble the components of the soil with the exception of the  $\text{SiO}_2$  content. The latter decreases with the increase in the degree of dispersion; it has no relation to the  $\text{SiO}_2$  content of the soil. The mineral fractions are almost the same in a solonetz-chestnut, solonetz-chernozem and podsolized soil with the exception of the  $\text{SiO}_2$  content and the compn. of the lowest fraction (particles less than 0.00025 mm.). The amount of humus, hygroscopic moisture and loss on ignition increases with the increase of the degree of dispersion. The  $\text{R}_2\text{O}_3$  content and at times the MnO and MgO increase also with the increase in the degree of dispersion, which indicates that these particles represent the more weathered products. The smallest fractions differ markedly from the coarser fractions, becoming low in  $\text{SiO}_2$  and  $\text{R}_2\text{O}_3$  and high in humus (up to 16%), CaO (up to 15%) and MgO (up to 11%). Apparently there are free hydroxides and vol. salts in the smallest fractions. Suspensions of southern chernozem, horizon A, of various degrees of dispersion are almost alike in their mineral and humus content, except again for the  $\text{SiO}_2$ , which decreases to the advantage of CaO and MgO. The suspensions of a solonetz soil from the B horizon are also alike, not excluding even the  $\text{SiO}_2$ . Only the very lowest fraction (particles less than 0.00025 mm.) contains less  $\text{SiO}_2$  and  $\text{R}_2\text{O}_3$ , more alkali, and has a higher loss on ignition. Suspensions of dark-colored degraded meadow soil are similar to podsolized soils in respect to the humus content and to solonetz soils in respect to the mineral compn. of the last 3 fractions. The humus of southern chernozem disperses but slightly. Suspensions are not composed entirely of hydrous Al silicates, or the so-called "zeolites"; they contain a number of substances not sol. in 10% HCl. The higher the degree of dispersion the more sol. are the substances in HCl. The soly. of suspensions from non-solonetz chernozem is relatively high and almost the same for all fractions. Al, Fe and Ca get into the HCl soln. more than any other constituent. Mg goes into soln. in small quantities or not at all. This indicates that Mg is in a more stable condition. With the increase in the degree of dispersion the amounts of Al and  $\text{SiO}_2$  increase when extd. with KOH. The ratios of  $\text{SiO}_2$  to  $\text{Al}_2\text{O}_3$  definitely show the presence of the hydrates of Al in the suspensions of the chernozem and podsolized soils, primarily in the lowest fraction. J. S. JOFFE

Soil acidity considered from the point of view of base exchange and hydrogen-ion concentration. PATRICK H. GALLAGHER. *J. Dept. Agr. Ireland* 28, 75–106(1929).—This paper is a review and discussion of investigations relating to the relation of base exchange to soil acidity, the measurement of H-ion concn., and the relation of the H-ion concn. of the soil to plant growth and the utilization of fertilizers. A bibliography of 72 references to the literature is appended. K. D. JACOB

Conditions of nitrification [in soil]. J. HENDRICK. *Proc. 1st Intern. Cong. Soil Sci.* 4, 175–82(1927).—Analysis of drainage water from variously fertilized soils indicates that nitrification can take place freely and for long periods in acid, chalk-free soil in spite of increasing acidity resulting from continued use of  $(\text{NH}_4)_2\text{SO}_4$ .  $(\text{NH}_4)_2\text{SO}_4$  is almost completely nitrified when used alone or in conjunction with other fertilizers, even when relatively large applications are made. Mineral fertilizers stimulate the activity of soil bacteria responsible for the decompn. of org. matter from which  $\text{NH}_3$  and ultimately nitrate is produced. The conception that the N of fertilizers may be utilized by soil organisms and stored in an insol. form within their tissues is discredited. No evidence is obtained that N in a gaseous form is lost from soil when excessive amts. of nitrogenous fertilizers are used. B. C. A.

Ammonium salts and calcareous soils. L. DEPARDON. *Ann. sci. agron.* 46, 308–16(1929).—In the application of ammoniacal fertilizers to highly calcareous soils whether or not a loss of N occurs depends upon (1) the water content of the soil, (2) its absorbing power (colloid content), (3) the quantity of fertilizer applied, and (4) depth of covering, if any. In all expts. comparable to field conditions, i.e., applications of  $(\text{NH}_4)_2\text{SO}_4$  up to 1000 kg. per hectare, water content over 2.7%, depth of covering at least 2 cm., no real loss of N was observed. This is explained by the rapid nitrification occurring under the moisture conditions existing at the end of winter and the beginning of spring. K. S. MARKLEY

Small-scale fertilizer experiments. C. M. HUTCHINSON. *Agr. J. India* 24, 21–4

(1929).—Errors in fertilizer plot expts., due to variations in the compn. and properties of the soil, are eliminated by removing and mixing thoroughly the surface soil. A 2-ft. layer of subsoil is next removed and mixed thoroughly. The subsoil and surface soil are then replaced and the area is divided into 4-ft. squares, sepd. by partitions of hard waxed paper. This method combines the desirable features of pot and plot expts. and eliminates many of the undesirable features of both. K. D. JACOB

**Fertilizer requirements of soils.** G. BARBIER. *Ann. sci. agron.* **46**, 292–307 (1929).—Liebig's law of diminishing returns is inexact as a criterion for detg. the soil requirements of fertilizing elements. Mitscherlich's method, widely used in Germany at present, depends upon the value, for a given element, of the "coefficient of efficacy" appearing in the equation of the law of growth of factors. Wiessmann's method of detg. the requirements of assimilable  $K_2O$  and  $P_2O_5$  is based on the use of the particular soil under investigation as the fertilizer for pure sand cultures. Guittonneau's method of detg. the phosphoric acid requirement depends upon the development of *Azotobacter*, which is detd. by a macroscopic technic. Neubauer's method depends upon the amt. of absorption of fertilizing elements by the roots of seedlings kept for 14 to 18 days in a mixt of soil and pure sand, as detd. subsequently by chem. analysis. K. S. MARKLEY

**The use of coal as a fertilizer.** A. D. KISSEL. *Trans. Fuel Conference, World Power Conference, London 1928* **1**, 80–101 (1929).—See C. A. **23**, 2780. A. H. E.

**Manganese deficiency in sand cultures.** L. P. MILLER. *Am. Fertilizer*, **68**, No. 7, 21–2 (1928).—Tomato plants grown in pure quartz sand contg. a nutrient soln. prepd. from high-grade chemicals soon developed a chlorotic condition due to Mn deficiency but quickly responded on the addn. of a small quantity of  $MnSO_4$ . Similar results were also obtained with corn, cabbage, wheat, barley and tobacco. To produce plants showing Mn deficiency is considered to be not much more difficult than to grow plants showing symptoms of N, P or K starvation. W. H. ROSS

**The application of artificial fertilizing means on moor soils.** K. HEITZ. *Künst-dünger u. Leim* **26**, 171–2 (1929).—The application of artificial fertilizing means on moor soils requires a special knowledge of their sp. mode of operation. Only when one considers this and constantly keeps in mind the changes in the moor, can one manage successfully with the aid of artificial fertilizers. E. F. SNYDER

**Concentrated fertilizers for potatoes in Aroostock County.** B. E. BROWN AND F. V. OWEN. *Me. Agr. Expt. Sta., Bull.* **350**, 1–44 (1929).—Field expts. are described. Difficulty experienced in distributing certain exptl. mixts. uniformly, due to poor phys. condition, was overcome by the addn. of a relatively small proportion of cottonseed-meal, or other org. material, to serve as a conditioner. With the use of  $KNO_3$ ,  $NH_4Cl$  and  $(NH_4)_2PO_4$ , no org. conditioner was necessary. C. R. F.

**Fertilizer requirements of the plum lands of the Agenais (France) region.** G. GUITTONNEAU, J. KEILLING AND M. BÉJAMBES. *Ann. sci. agron.* **46**, 255–91 (1929); cf. C. A. **23**, 4007.—A biochemical and microbiological study was made of the plum lands of the Agenais region with particular reference to the factors limiting the soil population such as humidity, aeration, the presence of fertilizing elements, e.g.,  $CaO$ ,  $CaCO_3$ ,  $KCl$ ,  $(NH_4)_2SO_4$ , phosphates, etc. The factor limiting proliferation of *Azotobacter*, in all, except the acid soils of Cardaillac, was found to be a deficiency in assimilable phosphoric acid. The technic and advantages of the *Azotobacter* method of detg. phosphoric acid requirements of soils are outlined. Fifty-seven references are appended. K. S. MARKLEY

**Fertilizer requirements of the cotton plant.** G. CHEVALIER. *Ann. sci. agron.* **46**, 320–30 (1929).—N is rapidly absorbed in the early stages of growth, decreasing with increasing maturity; about 40 kg. of sol. N, equiv. to 200 kg. of  $NH_4NO_3$ , or 250 kg.  $(NH_4)_2SO_4$ , per hectare is required. Phosphoric acid is absorbed rapidly at first and then slowly and continuously to the end of growth. Because of the beneficial action of phosphoric acid on the cotton fibers and of the very calcareous nature of the soil, it is most effective when applied as the superphosphate at the rate of 300 kg. per hectare. The K absorption was high at the beginning of growth, declined toward the flowering stage and increased again toward maturity. In spite of a  $K_2O$  content of the soil of from 3 to 8%, K should be applied at the rate of 50 kg. per hectare because of the insoly. of the naturally occurring form. It should be applied preferably as the sulfate because of the already high content of chlorides in the soil. Lime was not required. Fertilizer applications should be coincident with seeding. K. S. MARKLEY

**Activated phosphate (neutral phosphate) and the determination of the agricultural value of phosphate fertilizers.** GEORGES TRUFFAUT AND BEZSSONOV. *Chimie & industrie Special No.*, 692–7 (Feb., 1929); cf. C. A. **22**, 1846.—"Activated phosphate" is obtained by treating natural  $Ca_3(PO_4)_2$  with an amt. (5%) of  $H_2SO_4$  slightly greater than

that required for the decompn. and neutralization of the mineral impurities (silicates, carbonates, oxides, fluorides), or approx.  $\frac{1}{8}$  the amt. used in the manuf. of superphosphate. T. and B.'s biol. method for detg. the availability of  $P_2O_5$  (C. A. 23, 231) gave results in agreement with those of agricultural tests. The true fertilizing value of a phosphate fertilizer cannot be measured by its soly. in  $H_2O$  or  $NH_4$  citrate soln., or by the ratio of sol. to total  $P_2O_5$ . Though the soly. of activated phosphate is only about 40% that of superphosphate, its agricultural value is as great as that of superphosphate. "Reconstituted phosphate," prepd. by mixing mineral phosphate and superphosphate so as to obtain the same total and sol.  $P_2O_5$  contents as activated phosphate, has a distinctly lower fertilizing value than the activated phosphate. A. PAPINEAU-COUTURE

**A root growth experiment with Hevea.** H. W. ROY BERTRAND. *Trop. Agr.* (Ceylon) 72, 317-22 (1929).—Much greater root development was obtained with rubber trees treated with  $CaCN_2$  in pot expts. than with the same amts. of N derived from  $(NH_4)_2SO_4$ ,  $NaNO_3$ , fish scrap, tankage and other sources. The effect of N in org. ammoniates does not last any longer than that from inorg. salts in Ceylon. The soil temp. ranged from  $75^\circ$  to  $85^\circ$  F. and the rainfall was also high during the expts. A. L. M.

**Report of the Imperial Entomologist.** P. V. ISAAC. Agr. Research Inst., Pusa, *Sci. Repts.* 1927-28, 71-8 (1928).—Exposure to vapors from liquid Hg and Sn-Hg alloys gave very satisfactory control of insects in stored wheat. The germinating power of the treated grain was not affected, and flour made from the wheat was used by a family for 3 years without any deleterious effect on the health. K. D. JACOB

**Analysis of insecticides.** Liquid insecticides non-miscible with water: mixed hydrocarbons, carbon tetrachloride, nitrobenzene, naphthalene, methyl salicylate. MAURICE FRANÇOIS and MISS LAURE SÉGUIN. *Ann. fals.* 22, 226-32; *J. pharm. chim.* [8], 9, 49-58 (1929); cf. C. A. 21, 2355; 22, 3255, 3948. A. PAPINEAU-COUTURE

**The use of carbon dioxide to increase the insecticidal efficiency of fumigants.** R. T. COTTON and H. D. YOUNG. *Proc. Entomol. Soc. Washington* 31, 97-102 (1929); cf. C. A. 23, 441.— $CO_2$  when mixed with gaseous  $(CH_2Cl)_2$ ,  $CH_2ClO_2$ ,  $CS_2$ , chloropicrin and ethylene oxide accelerates the toxic action of these gases upon insects, permitting a reduction in both dosage and exposure time. It also removes or reduces the fire hazard of inflammable fumigants. The use of these mixts. in practical fumigation is discussed. C. H. RICHARDSON

**Studies of substitutes for arsenate of lead as a soil insecticide.** J. WILLIAM LIPP. *J. Econ. Entomol.* 22, 600-1 (1929).—Of 26 inorg. compds. mixed with soil in the amt. of 1500 lb. per acre, only  $Na_2SiF_6$ ,  $BaSiF_6$ ,  $Hg_2O_7$ ,  $HgI_2$  and  $HgCl$  killed the larvae of the Japanese beetle (*Popillia japonica*). The first 3 compds. mentioned did not affect the growth of grasses; the others were not tested for plant tolerance.  $Na_2SiF_6$  tends to harden soil, in some cases preventing the germination of grass seed.  $BaSiF_6$  does not so affect soil and soil treated with it was toxic to the larvae for at least 2 yrs. C. H. R.

**Notes on the ovicidal action of linseed oil.** J. WILLIAM LIPP. *J. Econ. Entomol.* 22, 594 (1929).—Linseed-oil emulsion has the following effect on eggs of the oriental fruit (peach) moth (*Laspeyresia molesta*) and the codling moth (*Carpocapsa pomonella*): (1) Susceptibility of the eggs to the oil varies with their age, incubation time, and concn. of oil in the emulsion; (2) a large no. of eggs pass through a partial development but fail to hatch; (3) the raw oil is more effective than the boiled oil; (4) emulsions made of oil contg. rosin are less effective than those made of oil without rosin. C. H. R.

**A note on the use of dried poison bait against locusts in the Sudan.** HAROLD H. KING. *Bull. Entomol. Research* 20, 99-101 (1929).—A bran-molasses-Na arsenite bait is sun-dried and moistened just before use. C. H. RICHARDSON

**The dangers of sulfating and soaking of seeds.** JAGUENAUD. *Compt. rend. acad. agr. France* 15, 770-1 (1929).—The tests made on wheat with different salts of Cu (phosphate, chloride, sulfate) have given marked variations in germination. Such preps. should be handled with caution. E. F. SNYDER

**The lethal dose of arsenic for the newly hatched codling moth larvae.** RALPH H. SMITH. *J. Econ. Entomol.* 22, 599-600 (1929).—The newly hatched larva of *Carpocapsa pomonella* may ingest 0.096 microg.  $As_2O_3$  by swallowing the apple skin on entering an apple sprayed with 2 lb.  $PbHASO_4$  in 100 gals. water. As the larva only swallows a portion of the apple skin in cutting through the surface, the amt. of  $As_2O_3$  ingested is probably much less, and is estd. as 0.0024-0.096 microg. The first particles swallowed by the larva may pass so rapidly through the body that only a small part of the ingested As is retained. Many larvae probably ingest As by coming in contact with it accidentally. C. H. RICHARDSON

**Investigations in codling control and removal of spray residue from pears.** F. W. PETTEY, ARTHUR SKIBBE and FRANÇOIS DE VILLIERS. Dept. Agr. Union S. Africa,

*Sci. Bull.* 64, 36 pp.(1928).—This investigation was carried out to det. whether the standard practice in spraying pear trees with Pb arsenate for control of the codling moth could be varied in such a manner that satisfactory control of the insect could be obtained without the necessity for treating the pears to remove arsenical spray residues. The results indicate that this is not possible, since in all cases where satisfactory control was obtained it was necessary to treat the pears for spray removal. Addn. of 3% of highly refined mineral oil to Pb arsenate sprays resulted in more effective control of the codling moth but retarded considerably the removal of arsenical residues from Kieffer pears by HCl. Better control was not obtained by adding Ca caseinate spreaders and molasses to the sprays. Bait traps contg. wine and fermenting apple juice were not effective. Pb chromate sprays were not satisfactory and  $\text{Na}_2\text{SiF}_6$  caused severe leaf burning. Most export varieties of pears of smallest export grade, which had received a full Pb arsenate spray program of double-strength sprays, required treatment for at least 2 min in 1% HCl soln., at a temp. not less than 70° F., to reduce the As to well below 0.01 grain per lb., and to remove all visible spray stains. Heavily sprayed Kieffer and Louise Bonne pears from inland localities required submergence for 3 min. in 1% acid for removal of all visible spray residue. Different varieties of pears were found to have different degrees of susceptibility to injury by HCl, the Duchesse, Clairegeau and Forelle being least susceptible, and Bartlett being most susceptible. Pears as a whole are more susceptible to injury by HCl solns. than are apples. Some varieties of pears tolerated 0.017% acid in the rinsing water without injury, while other varieties tolerated as much as 0.034%. The amt. of water required for rinsing acid-treated pears may be reduced as much as 60% by addn. of 1 lb.  $\text{NaHCO}_3$  to 100 gallons, without causing injury to the fruit in storage. Fruit picked and treated for As removal early in the morning is less susceptible to acid injury than fruit picked and treated at midday when the temp. is very high. K. D. JACOB

Laboratory studies in the control of codling-moth larvae on pears. F. W. PETTEY, Dept. Agr. Union S. Africa, *Sci. Bull.* 65, 13 pp.(1928); cf. preceding abstract.—Acid Pb arsenate gave more efficient control of codling moth on pears than was obtained with neutral Pb arsenate. Ca caseinate spreaders increased the efficiency of neutral Pb arsenate sprays, but had no effect on the efficiency of acid Pb arsenate sprays, better results being obtained, however, with the latter. In orchard tests, addn. of molasses to the sprays not only failed to produce better control of the codling moth but caused rusty spots to form on the surface of the fruit. Over half the codling larvae that escaped poisoning by 2 applications of standard Pb arsenate at normal and double concns. plus Ca caseinate spreader entered the lower half of full-grown pears where the spray film was probably thicker than in the upper half. The same was also true in the case of unsprayed pears. About 67% of the larvae that escaped the standard Pb arsenate sprays, contg. no spreader, on single full-grown pears entered between the spray blotches, and the great majority of the remainder entered at the margin of the blotches. K. D. J.

Soil treatment for control of the Japanese beetle. ERNEST N. CORY AND P. D. SANDERS. *J. Econ. Entomol.* 22, 556-61(1929).—A large-scale control operation with  $\text{CS}_2$  emulsion is described. C. H. RICHARDSON

Control measures for cucumber beetles. H. C. HUCKETT. N. Y. State Agr. Expt. Sta., *Tech. Bull.* 148, 82 pp.(1929); cf. C. A. 23, 3535.—Such heavy applications of dust or spray mixts. are necessary to protect seedling cucurbits from the striped cucumber beetle, *Diabrotica vittata*, and the spotted cucumber beetle, *D. duodecimpunctata*, that the development and yield of the plant are affected. Gypsum was less harmful than  $\text{Ca}(\text{OH})_2$  in dust mixts. A mixt. of 1 part Ca arsenate to 15 parts gypsum by wt. gave the best results. The beetles were readily killed by contact with  $\text{Ca}(\text{OH})_2$  but it had relatively little lethal value when applied to the foliage. Moisture rendered dust mixts. innocuous. The use of trap crops to segregate the beetles is described. C. H. RICHARDSON

The Mexican bean beetle, 1927-1928. C. O. EDDY AND W. H. CLARKE. S. C. Agr. Expt. Sta., *Bull.* 258, 41 pp.(1929).—In preliminary expts.  $\text{CaSiF}_6$  gave promising results as a dust or spray for the Mexican bean beetle, *Epilachna corrupta*; pyrethrum soap sprays also were very effective. Spraying and dusting machinery for use in dusting beans are discussed. C. H. RICHARDSON

Investigations on *Heterodera schachtii* in Lancashire and Cheshire. II. The relationship between degree of infestation and hygroscopic moisture, loss on ignition and  $\text{pH}$  value of the soil. A. M. SMITH. *Ann. Appl. Biol.* 16, 340-6(1929).—No correlation was found between hygroscopic soil moisture and loss of the soil on ignition and the degree of infestation with the beet worm, *H. schachtii*. The rate of reproduction is therefore probably not influenced markedly by normal variations in physical

condition of the soil. Some correlation exists between the no. of eelworm cysts and soil  $pH$  when the peat soils are considered. This did not appear to be true of the sandy soils.

C. H. RICHARDSON

**Tea in northeast India.** IV. P. H. CARPENTER. *Agr. J. India* 24, 48-59(1929); cf. C. A. 23, 1203.—The fertilization, control of insect pests and blights, and the processes used in the *prepn. of tea for the market* are discussed. The chem. and biological changes occurring during the manuf. of tea are but incompletely understood. Chem. investigations on the manuf. processes have been confined principally to studies on the changes in tannin content of the leaf. The *tannin content* changes from about 22% in fresh and withered leaves to about 12% in the processed material.

K. D. JACOB

**Report of the imperial mycologist.** W. McRAE. Agr. Research Inst., Pusa, *Sci. Repts.* 1927-28, 56-70(1928).—Fertilization with superphosphate appeared to favor spread of the *wilt disease of rahar* while green manures were unfavorable to it. The results of various expts. relating to the *mosaic disease* of sugar-cane are tabulated.

K. D. JACOB

**Apple spraying experiments in 1926 and 1927.** DONALD FOLSOM AND THEODORE T. AYERS. Me. Agr. Expt. Sta., *Bull.* 348, 145-76(1928).—Leaf burning in Ben Davis and McIntosh varieties was increased by spraying with dry lime-S especially in the late season applications. S dust reduced fruit scab more than leaf scab and caused some undesirable fruit russetting.

C. R. F.

**Apple scab and its control in northern Ireland.** I. ARTHUR E. MUSKETT AND EDMUND TURNER. *J. Ministry Agr. Northern Ireland* 2, 26-42(1929).—Expts. were carried out to det. the value of various fungicides in controlling apple scab caused by *Venturia inaequalis*. The best control was obtained with Bordeaux mixt. contg. sugar or glue. Addn. of Pb arsenate and casein spreaders did not increase the value of the mixt. Lime-S did not give good results but Burgundy mixt. gave good control without causing an appreciable amt. of leaf burn in these particular expts. Bordeaux mixt. was not satisfactory for very late spraying, because it left a thin powdery film on the fruit. For very late spraying lime-S, 1 to 60, should be used.

K. D. JACOB

**Control studies on the plum curculio in Connecticut apple orchards.** PHILIP GARMAN AND M. P. ZAPPE. Conn. Agri. Expt. Sta., *Bull.* 301, 437 pp.(1929).—A study of the life history, habits, parasites and control measures for the plum curculio, *Conotrachelus nemuphar*. Of the stomach poisons tested,  $PbHAsO_4$  was most effective. In lab. expts. capryl alc. was a powerful repellent to the beetle. For orchard control 4 applications of  $PbHAsO_4$  (1.5 lbs. in 50 gals. water) are recommended.

C. H. R.

**Mosaic and its control in other cane-growing countries.** WYNNE SAYER. *Agr. J. India* 24, 25-31(1929).—Methods used in various countries for control of the mosaic disease of sugar-cane are discussed.

K. D. JACOB

**The eggplant blight and fruit rot in Porto Rico.** J. A. B. NOLLA. *J. Dept. Agr. Porto Rico* 13, 35-57(1929).—The causative fungus, *Phomopsis vexans*, was effectively controlled by drenching the soil with 1 to 50  $CH_2O$  at the rate of  $\frac{1}{2}$  gal. per sq. ft. of surface. Neither Bordeaux mixt. (4-4-50) nor chem. seed treatment was entirely reliable as a control measure.

C. R. FELLERS

**The control of ordinary or late blight of the potato in northern Ireland.** ARTHUR E. MUSKETT. *J. Ministry Agr. Northern Ireland* 2, 54-62(1929).—A series of expts. on the control of the ordinary potato blight (*Phytophthora infestans*) showed that the use of dusting powders, as obtainable at present, was neither so efficient nor so economical as ordinary spraying.

K. D. JACOB

**The relation between flag smut infection and manurial treatment.** H. C. FORSTER AND A. J. VASEY. *J. Dept. Agr. Victoria* 27, 321-30(1929).—There was a close relation between the application of lime, in the form of  $CaO$  or basic slag, up to 1000 lbs. per acre and the percentage of flag smut (*Urocystis tritici*) infection on wheat and oats. Application of local farmyard manure also increased the infection, combinations of lime and farmyard manure giving particularly bad results. Application of various amts. of superphosphate had no effect on the percentage of plants affected with the disease.

K. D. JACOB

**Wildfire of tobacco.** I. Studies on overwintering and dissemination of wildfire. E. S. MOORE. Dept. Agr. Union S. Africa, *Sci. Bull.* 54, 5-19(1927). II. Methods of seed disinfection for the control of wildfire in Turkish tobacco. E. S. MOORE AND P. J. NAUDE. *Ibid* 20-3.—The formalin method of seed disinfection is not considered to be responsible for the germination failures occasionally reported in Turkish tobacco seedbeds. In order to prevent deterioration on storage, seed treated with formalin should be washed after treatment. Exposure to 0.5% soln. of Uspulun for 1 hr. or longer did not impair germination of the seed and seemed to give good control of wildfire.

AgNO<sub>3</sub> (1:1000) had no ill effect on germination of the seed when tested immediately after treatment. K. D. JACOB

C determination in soils by means of permanganic anhydride (DeNARDO) 7. The precipitation of CaC<sub>2</sub>O<sub>4</sub> in the presence of Fe, Al, Ti, Mn, Mg and phosphates, with special reference to the determination of total Ca [in soils and soil extracts] (CHAPMAN) 7. Diazonium fluorosulfonates [insecticides] (Brit. pat. 303,527) 25.

EMERSON, PAUL: *Principles of Soil Technology*. New York: The Macmillan Co.  
LYON, T. L., AND BUCKMAN, H. O.: *The Nature and Properties of the Soil*. A College Textbook of Edaphology. Revised ed. New York: The Macmillan Co.

**Fertilizer.** I. G. FARBERIND. A.-G. Brit. 303,916, Sept. 12, 1927. NaNO<sub>3</sub> and KNO<sub>3</sub> are used together (the NaNO<sub>3</sub> being less than 60%, and preferably 20–50% of the mixt.).

**Fertilizer.** I. G. FARBERIND. A.-G. Fr. 657,646, July 18, 1928. The products obtained by heating NH<sub>4</sub>CNS, or its primary heat decompn. products such as thiourea and guanidine thiocyanate, until the cessation of gas liberation, are excellent N fertilizers.

**Fertilizer.** FRIEDRICH L. SCHMIDT. Fr. 658,076, July 25, 1928. A mixed fertilizer contg. phosphoric acid and potash is obtained by decomposing by heat the double bicarbonate of K and Mg (MgCO<sub>3</sub>.KHCO<sub>3</sub>) as aq. emulsion, the soln. of K<sub>2</sub>CO<sub>3</sub> thus obtained being afterwards sepd. from the pptd. MgCO<sub>3</sub> and used for decomposing mineral phosphate, the MgCO<sub>3</sub> being used to reform the double bicarbonate.

**Fertilizers.** RHEINLAND-KUNHEIM VEREIN CHEMISCHER FABRIKEN A.-G. Fr. 34,257, June 24, 1927. Addn. to 598,203. In the production of a fertilizer by heating mixts. of phosphorite and H<sub>2</sub>SiO<sub>3</sub> in the presence of steam and with the addn. of Na<sub>2</sub>SO<sub>4</sub> or NaCl, the amt. of H<sub>2</sub>SiO<sub>3</sub> added is reduced so that 1/2 mol. of H<sub>2</sub>SiO<sub>3</sub> is added for 1 mol of P<sub>2</sub>O<sub>5</sub>. Cf. C. A. 23, 1208.

**Fertilizers.** SOC. CHIM. DE LA GRANDE-PAROISSE, AZOTE & PRODUITS CHIM. Fr. 657,893, Mar. 2, 1927. Salts, which by their manner of manuf. contain a certain amt of volatile NH<sub>4</sub> compds. such as salts formed in the manuf. of NH<sub>4</sub>Cl by the action of NH<sub>3</sub>, CO<sub>2</sub> and NaCl, are treated with SO<sub>2</sub> to form (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> which oxidizes to (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, and are used as fertilizers.

**Limestone for use as fertilizer.** W. E. CARSON. U. S. 1,721,803, July 23. Moist limestone is mixed with quicklime and the mixt. is ground to a powder, which, with the proportions of ingredients which are used, will not contain sufficient free moisture to form a hard solid cake when subjected to a temp. below freezing.

**Flower pots which decompose in the ground and serve as fertilizing material.** J. J. H. STURMEY. Brit. 303,394, Sept. 26, 1927. A pot may be formed by passing pulped peat into a foraminous mold and compacting and drying the residue. Wood pulp with addn. of Na<sub>2</sub>SO<sub>4</sub> also may be used, and pots formed of wood pulp may be impregnated with fertilizing substances.

**Fertilizer and insecticide.** R. TOYER. Brit. 303,957, Dec. 8, 1927. A mixt. is used comprising soot, lime, sand, sawdust, coal-tar or wood-tar oil and paraffin

**Disinfectant, fungicidal and wood-preserving compositions.** I. G. FARBERIND A.-G., W. BONRATH AND W. SCHEPSS. Brit. 303,932, Oct. 17, 1927. Salts of basic dyes such as the oxalate or ZnCl<sub>2</sub> double salts (e. g., the oxalic salt of malachite green) are mixed with an arsenic or arsenious acid or salt. Various examples are given.

**Spraying agricultural insecticides.** JOHN E. SHEPHERD and EDWIN K. O'BRIEN (to Belle Mead Development Corp.). U. S. 1,723,955, Aug. 6. A blast of steam is liberated into free air and there is introduced into the blast an insecticide including fuel oil or other suitable oily liquid and a dry material such as S or Ca arsenate. An app. is described.

## 16—THE FERMENTATION INDUSTRIES

C. N. FREY

**Preparation of absolute alcohol by the use of lime under pressure.** O. VON KEUSSLER. *Z. Spiritusind.* 52, 147–8(1929); cf. C. A. 23, 2239.—At 4–5 atm. pressure only 1.5 hrs. is required for the reaction. A. SCHULTZ

**Manufacture of absolute alcohol by the alcohol-benzene distillation under pressure.** O. VON KEUSSLER. *Z. Spiritusind.* 52, 36–8(1929); cf. C. A. 23, 234.—By increasing

the pressure of distn. to 10 atm. Merck improved Young's method of manufg. abs. alc. from a min. b. p. mixt. of alc. and benzene. At 10 atm. (b. p. 144°) the amount of water removed from the alc. by the benzene is 2.6 times greater than that at 0 atm. (b. p. 65°). In practice enough benzene is used with benzine to act as a solvent between the aq. alc. and the benzine. At the higher pressure less benzene is required to facilitate the distn.

A. SCHULTZ

**The detection of isopropyl alcohol in spirits with the acid of the Griebel micro-technic.** F. WEISS. *Z. Untersuch. Lebensm.* 57, 45-8(1929).—Oxidize 0.1 cc. of the alc. mixt. with chromic acid. Boil with  $\text{Ag}_2\text{O}$  to remove the  $\text{AcH}$ . Acetone formed from  $\text{Me}_2\text{CHOH}$  is detected by means of *m*-nitrophenylhydrazine by the Griebel micro-cup technic. One % of isopropyl alcohol can be readily detected by this procedure.

C. R. FELLERS

**First chemical phases of hexose decomposition in alcoholic fermentation.** A. J. KLUIJVER AND A. P. STRUIJK. *Wochschr. Brau.* 46, 51-5(1929); cf. *C. A.* 23, 2530.—By increasing the concn. of the yeast macerate a high max. rate of evolution of  $\text{CO}_2$  in cell-free fermentation was brought about during the phosphorylation period with a low ratio of hexose monophosphate to diphosphate. According to the theories of Harden, Henley and Meyerhof the mol. ratio of the increase of  $\text{CO}_2$  during the phosphorylation period to the hexose diphosphate found should be 2:1. The authors' value for this ratio was as high as 11.4. These facts show that Robinsons' hexose monophosphate results from an active hexose monophosphate and that the hexose diphosphate is formed by the combination of 2 mols. of glyceraldehyde monophosphate.

A. SCHULTZ

**Adjustment of acidity of cane-molasses fermentations for maximum alcohol yields.** F. M. HILDEBRANDT. *Ind. Eng. Chem.* 21, 779-81(1929).—A method for obtaining the max. alc. yield from cane molasses by fermentations with the addn. of acid involves the use of the potentiometer and quinhydrone electrode. The max. yield is obtained when sufficient acid is added to prevent the  $p_{\text{H}}$  of the fermentation soln. drifting to the acid side during fermentation.

J. T. WOLF

**Glycerol from molasses.** P. V. GOLOVIN. *Zhur. Sakharnoi Prom.* 1, 22-5(1927).—Equal vols. of molasses and hot water are mixed with turf powder and boiled for one hr. By this operation free volatile org. acids are driven off. The soln. is sterilized and some substances are adsorbed by the turf. Then the soln. is dild. to 10-12° Bé. at 30°, and  $\text{NH}_4$  salts, phosphates and calcium and 5% of yeast on the wt. of sugar in molasses are added. Fermentation is accomplished in 36-48 hrs. in alk. medium in presence of bisulfites of Na and compds. of Ca and Mn. At the end of fermentation the soln. is distd. to eliminate alc. and aldehyde. The remaining liquid mass contains much sulfite, which can be pptd. by  $\text{CaO}$ . The soln. is refiltered and the alk. of the filtrate is neutralized by  $\text{CO}_2$  and  $\text{H}_2\text{SO}_4$ . The crude glycerol is concd. and distd. in a current of superheated steam. Glycerol 20%, alc. 20% (87.5°) and aldehyde 8% were obtained.

V. E. B.

**Benzoic and salicylic acids in alcoholic beverages.** F. DAELS. *Bull. acad. méd. Belg* 1, 28(1928); *Quart. J. Pharm. and Pharmacol.* 2, 83.—The following methods are recommended: 150 g. of sample is shaken with 20 cc. of Pb subacetate soln. (10%) and 5 cc. of soln. of  $\text{NH}_4\text{OH}$  (d. 0.90) and filtered. The filtrate is shaken with 2 g. of  $\text{KHSO}_4$  to remove the excess of Pb and render the soln. acid. After removal of  $\text{PbSO}_4$  by filtration, the soln. is extd. with half its vol. of ether, the ether washed with a little water and evapd. The residue is treated with a ferric salt. A pink color indicates benzoic acid; a violet color indicates salicylic acid or possibly a mixt. of the two acids. The detn. is carried out as above, 100 cc. of the filtrate being used. If both acids are present, the salicylic acid is removed by conversion to picric acid and then to chloropicrin. The residue is treated with 4 to 5 cc. of dil.  $\text{HNO}_3$  and carefully evapd. to dryness, taken up again with 100 cc. of water, 6 g. of bleaching powder added, and warmed on a water-bath for 10 min. The chloropicrin so formed is volatilized. The soln. is filtered, made slightly acid with  $\text{H}_2\text{SO}_4$  and the pptd.  $\text{CaSO}_4$  filtered out. The benzoic acid is extd. with ether and weighed. From the wt. of benzoic acid and the total wt., the salicylic acid can be calcd.

H. L. D.

**Processes for the preparation of sweet ciders.** G. WARCOLLIER AND LE MOAL. *Chimie & industrie, Special No.*, 624-32(Feb., 1929).—There are 2 types of sweet ciders, (a) those obtained by sweetening completely fermented cider by addn. of unfermented apple juice, (b) those which have been kept naturally sweet by incomplete fermentation. The various processes of production of these 2 types are described.

A. P.-C.

**Composition of fusel oils which have been separated as vapor.** B. LAMPE. *Z. Spiritusind.* 52, 190(1929).—A table giving the commercial evaluation of 7 fusel oils and their  $\text{AmOH}$  contents, obtained by fractional distn., shows that the former methods

are misleading. For the same commercial rating the difference in AmOH found by fractional distn. was as high as 20%. A. SCHULTZ

**Determination of starch value of sound and frozen potatoes, with reference to their use for distilling and drying.** B. LAMPE AND W. KILP. *Z. Spiritusind.* 52, 177-8 (1929).—Two samples of frozen potatoes were used, the one apparently sound and the other softened and attacked by bacteria. The starch contents detd. by (1) calcn. from the sp. gr., (2) acid hydrolysis and Fehling's soln., (3) hydrolysis, fermentation and detn of alc. and (4) subtracting 5.8% from the dry matter were, respectively, 16.7, 16.97, 16.82, 16.77% on the sound and 12.0, 23.45, 24.26 and 24.75% on the unsound sample. The applicability of the sp. gr. method for the detn. of starch in unsound potatoes is discussed. A. SCHULTZ

**Modern malting methods.** G. CHABOT. *Wochschr. Brau.* 46, 208-11 (1929).—The optimum  $p_H$  of the steep water is 6-7. With slightly more acid or alk. steep waters the  $p_H$  tends to adjust itself to the above value. Alk. steep water tends to darken the grain. A. SCHULTZ

**Liquefying and saccharifying powers of German malts of the 1928 harvest.** H. LÜERS AND F. WIENINGER. *Wochschr. Brau.* 46, 173-4 (1929). A. SCHULTZ

**Chemical composition of the barleys and malts of 1926 and their worts and beers.** W. WINDISCH, P. KOLBACH AND W. BANHOLZER. *Wochschr. Brau.* 46, 223-8, 235-40 (1929); cf. *C. A.* 22, 2806. A. SCHULTZ

**Determination of tannin.** B. D. HARTONG. *Wochschr. Brau.* 46, 11-15 (1929).—A method is outlined for detg. tannin in beer and wort by titrating the soln. before and after absorbing with casein with 0.01 N  $KMnO_4$ , indigo soln. being used as an indicator. A. SCHULTZ

**Practical experiments on the significance of hop tannins for wort and beer.** H. BILGRAM. *Wochschr. Brau.* 46, 137-41 (1929).—Hop tannins besides improving the flavor of beer ppt. higher albumins and thus produce a clear wort and beer. A hop tannin treatment of pale beers to remove protein material did not prevent these beers from becoming cloudy after pasteurization. A. SCHULTZ

**Hydrogen-ion action in the brewing industry. IV. 2. The effect of the hydrogen-ion concentration on fermentation.** G. HAGUES. *Wochschr. Brau.* 46, 178-82; *J. Inst. Brewing* 35, 51-60 (1929).—The detn. of the reproductive powers of 4 organisms in wort of varying  $p_H$  values has shown that the growth of *Torula* depends upon one enzyme or one group of enzymes whose optimum lies at  $p_H$  5, that the growth of *Sacch. ellipsoideus* and *Sacch. cerevisiae* depends upon two enzymes having optimum  $p_H$  at 4 and 8.5 and besides these two *Pastorianus* yeasts have a third optimum at 6.5. Growing *Pastorianus* I and *Sacch. cerevisiae* in the same wort was harmful to both. A. SCHULTZ

**Improvement of brewing waters of high carbonate content by lactic acid.** V. KOUDELKA. *Wochschr. Brau.* 46, 164-70, 174-8 (1929).—Addn. of lactic acid to hard waters used in brewing improves them more than the lime or  $CaCl_2$ . Lactic acid stimulates protease and phosphatase action but an excess retards diastatic action. A better "break" results in these lactic acid-treated worts. Also the yeast settles better and the beers are paler and have a finer flavor. A. SCHULTZ

**Rapid estimation of nitrogen by Kjeldahl's method.** H. LUNDEN AND J. ELLBORG. *Wochschr. Brau.* 46, 133-7, 147-9 (1929).—Acid digestion of malt, beer, wort, etc., can be completed in 8-12 min. For example, 1-2 g. of malt is digested over a microburner in a 500-cc. flask with 10-20 cc. of 30%  $H_2O_2$ , 0.5 g. copper wire and 10 cc. of a mixt. of 3 vols. concd.  $H_2SO_4$  and 2 vols. 85%  $H_3PO_4$ . After this vigorous action 7 g. of  $K_2SO_4$  is added and the mixt. boiled 5 min. with an ordinary burner. A. SCHULTZ
